His work in the realms of preventive medicine has never been equalled, and although not always appreciated as it ought to have been, yet it stands as a monument which time cannot efface.

To clinical veterinary medicine and surgery he has made such solid additions that the value of his observations is vividly brought before the practitioner in his daily work. For W. Hunting exposed many "fads and fallacies" in diagnosis and treatment, besides contributing several original observations on the diagnosis of lameness, and the symptomatology of various diseases. His observations led practitioners to think for themselves, to avoid mistaking the shadow for the substance, and to distinguish consequences from coincidences. Accuracy in observation, a sincere desire for the discovery of clinical facts, and a contempt for assumed skill, were leading characteristics in his nature.

In addition to the qualities mentioned, who can forget his charming manner, and his willingness at all times to discuss difficult problems in veterinary science. He was the same to the humblest practitioner as to the one of the highest standing, and this was one of the reasons why the name of W. Hunting was a household word in the profession, and why he was honoured, respected, and loved by every practitioner in the British Isles. And it can be said without exaggeration that to have known W. Hunting was in the deepest and truest sense of the phrase a liberal education, and each one of us must re-

echo the following lines while we mourn for "the sound of a voice that is stilled" :—

"Whatever way my days decline,
I felt and feel, tho' left alone,
His being working in mine own,
The foot-steps of his life in mine."

To perpetuate the memory of so great a man is the duty of the profession of which he was so truly an adornment. As to what form the memorial should take, opinions may differ, but we might well follow the sister profession by instituting a lectureship on similar lines to the Lettsomian, Harben, Milroy, and similar lectures. This would be a perpetual and living memorial, and the matter is at least worth consideration.

E. WALLIS HOARE.

THE LATE MR. WILLIAM HUNTING.

The deceased gentleman was born in Camberwell, and therefore he is by birth a Londoner; his mother (née O'Higgins) was an Irish lady. At the age of five years he accompanied his parents to South Hetton, where his father in 1851 obtained, through the instigation of the late Prof. Spooner, an appointment; he received his general education at the Edinburgh Academy and his professional education at Gamgee's New Edinburgh Veterinary College, subsequent to this he finally settled in the city of his birth—London—where he established his reputation.

Therefore, the three nations, Ireland, England, and Scotland, have all assisted in the career of the late William Hunting.

HENRY GRAY.

Iceland Ponies.

Iceland ponies are exported annually to the number of (approximately) 2,500, whose value is estimated at £12,000. They are chiefly sent to Denmark: in 1911 490 were exported to the United Kingdom, and their value was £2,332. They do well almost invariably in this country, and may be relied upon to get through a lot of work.

An admirer of these ponies thus comments: "Their early conditions, climatic and otherwise, tend to give them a good constitution, and it is a case of survival of the fittest. They are, as a rule, good-tempered and easily managed; they are hardy and willing, with plenty of stamina. Their legs and feet do not leave much to be desired, and they are fine "doers" in the stable. They seem to thrive even when the material conditions are against them to some extent."—*Live Stock Journal*.

Hunting Memorial.

It has been brought to my notice that there is a desire amongst the members of the profession and friends of the late William Hunting to perpetuate his memory.

A meeting will be held at the Royal College of Veterinary Surgeons, 10 Red Lion Square, W.C., on Thursday, Nov. 13th, at 7.30 p.m., to consider proposals for carrying this into effect. It is hoped that all those who are interested in the movement will be present.

HENRY GRAY.

23 Upper Phillimore Place, W.

Personal.

JEFFRIES.—On March 4th, at York House, London Road, Guildford, the wife of H. Haywood Jeffries, M.R.C.V.S., of a son.

The late Sir RICHARD COOPER, of Lichfield, chemical manufacturer, and one of the leading stock breeders in the country, left £519,300. He stated in his will:—

"I make no charitable bequests (in the sense in which the word charity is commonly used), because I am confident that my son will continue what appears to me the best form of charity, namely, to remember with kindness all those who have been friends or intimate acquaintances of myself and family, and will give them financial help in all cases where they stand in need of it."

OBITUARY

EDWARD NETTLESHIP, F.R.C.S., F.R.S., M.R.C.V.S., Hindhead, Surrey. Graduated, Lond: May, 1867.

Edward Nettleship, F.R.C.S., F.R.S., M.R.C.V.S.

The death of Mr. Edward Nettleship took place on Oct. 30th at his residence at the Longdown Hollow, Hindhead, Surrey, in his 69th year. He was born at Kettering on March 3rd, 1845, and was educated in his natal town. Some time after he had obtained the Membership Diploma of the Royal College of Veterinary Surgeons, he succeeded the late Mr. Wm. Hunting, F.R.C.V.S., as Professor of Veterinary Science at the Royal Agricultural College, Cirencester, but after a short stay there he returned to London to study human medicine, in which he afterwards made himself famous. Early in his career as a medical man he gained for himself a great reputation in ophthalmology, and became consulting surgeon to the Royal London Ophthalmic Hospital and St. Thomas' Hospital.

In 1891 he was consulted by Mr. Gladstone, upon whom he operated for cataract with great success, and hence his name became known far and wide.

He wrote numerous articles on ophthalmological subjects, and published a little work on "Diseases of the Eye," which became for a great number of years the standard book on the subject for students and junior practitioners, both medical and veterinary.

During the past two years he, in collaboration with Prof. Karl Pearson and Mr. Usher, brought out a series of volumes on the question of Albinism in man and in animals, including among other subjects "wall-eye" in horses. In 1912 he was elected a Fellow of the Royal Society of London, the most coveted honour a scientific man can obtain.

A few years ago Mr. Nettleship retired from practice, but during his retirement he took a great interest in many questions relating to this profession, and within the past few months published, in conjunction with Mr. A. C. Hudson, a valuable paper "On Optic Neuritis without Intra-cranial disease, in a pedigree bull," a copy of which he sent to several of his veterinary friends. He was greatly interested in the problem why roaring

in horses generally affected the *left* recurrent nerve. Hardly five weeks before his death he was in active correspondence with members of his old profession on these and allied subjects, so keen was his desire for knowledge.

Two years ago he underwent a severe operation with complete success after a prolonged after-treatment, and had an attack of influenza last spring. On the writer of this notice enquiring on Sept. 20th as to his health he replied: "Thank you, I am quite well, but find that one cannot at my age have illnesses for nothing."

In 1869 he married Elizabeth Endacott, daughter of Mr. R. Whiteway, of Compton, Devon, who survives him.

It is worthy of note that a professional training in veterinary medicine has been the starting point of many men, who have afterwards become famous in human medicine. Among such were Joseph Sampson Gamgee, Thos. Orme Dudfield, late Medical Officer of the Royal Borough of Kensington, Balfour of Edinburgh, Raymond, the successor of Charcot at the Saltpetrière, who a year or two before his death received the LL.D., Oxford (Hon. Caus.)

MR. GEORGE D. HOYLAND, V.S., Wombwell View, Barnsley, Yorkshire. Death occurred on Nov. 3rd, from Carcinoma of liver. Aged 68 years.

CORRESPONDENCE.**DIAGNOSIS.**

Sir,

I must again crave your indulgence in order to answer Mr. McKenny's question. The question is easily disposed of—the answer is in the negative, *cela va sans le dire*. But I still deny that, in any of the articles for which I am responsible, or in those which have appeared in connection with the subject, the impression could be conveyed to a reader of ordinary intelligence that the writers intended their confessed "want of skill" to apply to all members of the profession. Most of your readers understand that if a writer chooses to employ the first person plural, it does not by any means indicate that said writer "arrogates to himself the prerogative of measuring the skill and ability of others." If Mr. McKenny holds an opposite view, then we shall "agree to differ."

Fortunately Mr. McKenny has not used the first person plural, otherwise the public might expect a similar degree of skill in other practitioners. Mr. McKenny says that whenever he formed a definite opinion on a case, the cadaveric lesions most satisfactorily corroborated his ante-mortem diagnosis. He does not, however, give us the proportion of cases in which he forms a definite opinion. Very much depends on this. If he forms a definite opinion in a large number of cases and finds that said opinion is always supported by post-mortem evidence when the cases succumb, then indeed he must have exceptional skill in diagnosis.

When Mr. McKenny says that he frequently finds "most interesting specimens apart from the ailments from which the animal was suffering," does he mean to infer that no symptoms were associated with the presence of such lesions? If so, the clinical interest falls to zero.

"A good reputation and confidence in one's ability to diagnose cases," do not always go hand in hand with knowledge, nor with wisdom, but they are essential attributes to the *savoir vivre*. The days of hero-worship are getting numbered. The public are commencing to estimate the stoic, not at his own valuation, but by another standard. The man who fancies that he is immune to errors, although he still may be able to persuade certain clients of his superiority, soon loses his influence in this direction. He may fool some of the people all the time, all of the people some of the time, but he cannot fool all of the people all the time.—Yours, etc.,

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1323.

NOVEMBER 15, 1913.

VOL. XXVI.

NEXT YEAR'S REGISTER.

The Register is now undergoing revision; and all changes of address ought to be notified to the Registrar before the end of this month. As we have pointed out, this imposes a double obligation upon us all—to report our own changes of address and of others within our knowledge which are likely to be unreported. The first we do for our own sakes; the second we ought to regard as a public duty. It is to the interest of the profession and the public alike that the Register should be as accurate as possible; members generally will assist the Registrar by sending the necessary information.

SIR THOMAS ELLIOTT.

The report of the dinner given by the Royal Agricultural Society to Sir Thomas Elliott is a pleasant record of a well-deserved compliment; and the names of those attending it testify to the guest's widespread popularity. On the other hand, it marks the loss to the Board of Agriculture of one of the best servants that that body has ever possessed. In his long official career Sir Thomas Elliott has done excellent service to the nation; and we in the veterinary profession have especial cause to remember him with gratitude. Throughout his tenure of office at the Board, he was brought into close touch with its veterinary branch, and quickly realised its usefulness. This led him to encourage veterinary activity within the Department, and, as a Governor, of assisting the Camden Town School. In both capacities he has steadily furthered our development; and for many years past the profession has had no better friend outside its ranks than Sir Thomas Elliott. All members recognise this—those with inside knowledge realise it most clearly—and all will join in good wishes for his future.

THE MUTABILITY OF THE TUBERCLE BACILLUS.

Prof. Alex. James' lecture upon this subject, which we printed last week enunciates a heterodoxy which every year brings nearer to the realm of probability. Some family connection between the various acid-fast bacilli is now generally accepted; but its nature is merely surmise, and the existing differences between the species are only imperfectly understood. That being so, it would be premature to deny the possibility of a speedy mutation of one species into another because no such mutation has yet been proved. Clinical facts, such as the

comparative frequency of tuberculosis among un-housed cattle in New Zealand and elsewhere, and bacteriological experience, such as the great variations in pathogenicity known to exist amongst tubercle bacilli, support the view of mutation more or less. Assuming that such mutation is possible, it may not take place easily or rapidly in natural conditions, but it is conceivable that special circumstances may facilitate it.

The question is only likely to be settled by exhaustive comparative studies of the chemistry and biology of the various acid-fast bacilli—mostly of comparatively recent discovery, and new facts have lately been gained regarding even those longest known. Their possible mutability is being studied, with other questions, in various laboratories. It may not greatly affect the problem of tuberculosis at present; but the influence upon future work may be profound. At present, in the campaign against tuberculosis, we are concerned only with the affected animal. But when the disease as it exists now is brought under control, the mutability of acid-fast bacilli may be an obstacle in the way of its complete eradication.

TREATMENT OF "POLL EVIL" WITHOUT OPERATION.

The horse in question was affected some six weeks before my attention was directed to it, and he had been worked until he could work no longer.

The symptoms were—head very depressed, and the nose almost touching the ground. On my trying to raise it the horse almost dropped, owing, I expect, to pressure on the cord at the atlanto-axial joint. The swelling over the region of the poll extended about 12 inches from before backwards, and about 18 inches laterally, with four fistulæ on the off side and two on the near, discharging a sanguino-purulent fluid with a most offensive odour. Breathing stertorous, and animal in poor condition.

I tried to open up the fistulæ, but at the first probe the horse fell as if "pithed," so had to give that up, and contented myself with syringing out the sinuses with Hydrogen peroxide (10 vols.) until they were clear, and then injecting "Phylacogens," (P. D. & Co.)

I left instructions for the discharges to be washed off daily, and the skin to be kept clean. This was on August 15th, 1913.

August 18th.—Less discharge and very little odour. Repeated treatment.

August 25th.—Continued improvement; treatment repeated.

Sept. 1st.—Discharge absent on the near side, and horse could move head easily and naturally. Feeding well, and condition very much improved. Treatment continued.

Sept. 8th.—Been neglected by man in charge, who did not clear off discharge, which could not get away. Dressed and cleansed, and injected phylacogens.

Sept. 13th to Oct. 4th.—Injected phylacogens, but did not use Hyd. peroxide as discharge had ceased, and on Oct. 4th the skin wounds had healed; horse put to work and is still working and showing no signs of a relapse.

Being single-handed in a wide country practice, and the case some miles away, I could not attend oftener. I consider this an extraordinary cure, as I thought any treatment would be useless. From the very first dose of the phylacogens the case began to improve, and except about September 8th, when the man neglected to cleanse the parts, there was no retrogression. In future I shall leave operation for this condition alone, at least until I have tried the same treatment and failed. I am also convinced that the time of treatment could have been reduced to one half—or less, had I been able to dress the wounds and inject the phylacogens daily, or at least every other day. J. M.

TREATMENT OF CANCER OF THE FOOT OF THE HORSE BY THE INTERNAL ADMINISTRATION OF ARSENIOUS ACID.

An article was recently published by Major J. D. E. Holmes, C.V.D., on the treatment of cancer of the horse's foot by the internal administration of arsenious acid in large doses. This treatment has been tried this year in the Station Veterinary Hospital, Lucknow, on two cases, with very satisfactory results. Both were Australian horses from the R.F.A.

The first case was badly affected on one fore foot, the foot was deformed and the horse very lame, a pronounced chronic case, which had been twice previously treated with only partial success.

The second case was diseased in all four feet.

Treatment consisted in the administration of arsenious acid in bolus in three courses, with an interval of seven to fourteen days between each course. The doses, ten in number in each case, were given on alternate days, commencing with one gramme, and gradually increased to three grammes.

On the completion of the third course both cases were cured, one on May 6th, the other on July 14th. Up to the present time there has been no re-appearance of the disease, and both horses are at work.

The only local treatment adopted was pressure, and the application of a dry antiseptic dressing.

The duration of the treatment of each case was approximately 3½ months.

J. J. HILLARD, Lieut. A.V.C.

Lucknow. Oct. 15.

ABSTRACTS FROM FOREIGN JOURNALS.

SODIUM HYPOSULPHITE IN THE TREATMENT OF DISTEMPER.

Teppaz has published (*Rev. Générale de Méd. Vét.*) a communication upon this subject. He read in a sporting journal that small doses (7½ to 15 grains) of hyposulphite of sodium gave "marvellous" results in distemper. He therefore tried it, and now uses it systematically, to the exclusion of all other internal medicaments, in all cases of distemper, whatever their form. He has thus treated about sixty cases, the majority of which have recovered.

At the commencement of the illness, Teppaz gives a purgative consisting of equal parts of calomel and scammony (4½ to 7½ grains each). He follows this by giving one dose daily of sodium hyposulphite (9 to 15 grains) in milk or sugar and water, commencing the day after purgation. He considers it very useful to simultaneously employ counter-irritants in the case of respiratory symptoms.

Under the influence of this treatment, the catarrh and cough of the respiratory form of distemper diminish. In the gastro-intestinal form the diarrhoea abates, the excrements harden and develop a pronounced odour of sulphuretted hydrogen, and the appetite returns. It is rarely necessary to give the hyposulphite for more than ten days.—*Annales de Méd. Vét.*

[Finlay Dun mentions hyposulphite of sodium for distemper, stating the dose at from ten to twenty grains twice daily. Many years ago I tried it in a few cases, and obtained good though not brilliant results; but I did not use it long enough to form any strong opinion of its value. I never prefaced its administration by such a purgative as is prescribed above.—TRANSL.]

FOREIGN BODY IN THE LUNG OF A DOG.

Knitl, of Neumarkt, records the following case in a valuable hunting dog. While out hunting, a piece of bread was thrown upon the ground before the dog. He bolted it greedily, and from that moment refused all food. During the next few days no special symptoms of illness could be seen in him, beyond refusal of food and an acceleration of the respiration. On the sixth day he died.

The post-mortem examination was surprising, as it revealed a foreign body in the shape of a sharp pine twig about two inches long in the right lung. The foreign body had already penetrated the pulmonary pleura; but the canal which it had formed had not yet broken down into pus.

A peculiar feature of the case was that neither coughing nor fever was shown during the whole period of the illness, and that even examination with the phonendoscope failed to reveal any abnormal sounds in the lung.—(*Münchener Tier. Woch.*) W. R. C.

[This case suggests the possibility that similar ones may occur unrecognised more frequently than is generally supposed.—*Transl.*]

COLON-TYPHOID ORGANISMS IN HOG CHOLERA.

A bacteriological study was made with the object of determining whether or not hog cholera bacilli or related organisms belonging to the bacillus enteritidis group were present in the carcasses of hogs, which at autopsy showed lesions of hog cholera.

The results of this investigation showed that organisms of the colon-typhoid group were almost constantly present in the livers of normal hogs, but seldom in the other tissues. In the case of hogs affected with hog cholera, colon-typhoid organisms were not only present in the liver, but were quite generally distributed throughout the other tissues as well. There appeared to be little, if any, difference in the occurrence and distribution of colon-typhoid organisms in the three classes of cholera hogs studied—that is, colon-typhoid organisms were present as frequently in organs and tissues of carcasses showing slight cholera lesions as in the carcasses showing extensive cholera lesions. No organisms of the

bacillus enteritidis, or so-called hog cholera group, were found. The organisms referred to as belonging to the colon-typhoid group, presented the usual characters of the colon bacillus, some strains fermenting glucose and saccharose, and some only glucose and lactose.

There were also organisms which correspond with the classical description of bacillus fecalis alkaligenes. No organisms corresponding to the typhoid bacillus were found.

CARCASE VALUES.

The bones and trimmings were found to average per carcass as follow:—Cattle, 24 per cent. of the dressed weight; calves, 30.5 per cent.; sheep and lambs, 25.5 per cent.; and swine, 15 per cent. The dressed weight in the latter includes the lard. When these percentages are applied to the total weight of meat annually consumed, it appears that fully 3,000,000,000 pounds, or 20 per cent. of the dressed meat sold for consumption, is composed of non-edible material.

The extra-edible parts of the various animals were found to average as follows, excluding the edible tallow so as to confine our data, as before, to meat proper:—Cattle, 41·87 pounds; calves, 9·47 pounds; sheep and lambs, 1·03 pounds; swine, 25·05 pounds. The edible tallow, it may be remarked, is practically all supplied by adult cattle, the averages per animal being:—Cattle, 56·22 pounds; calves, 0·22 of a pound; sheep and lambs, 1·03 pounds. The lard of swine has already been estimated in the preceding chapter to be 27·27 pounds per animal.

It may be observed, in passing, how the above results emphasise the superior economy of the swine carcass. It is lowest in percentage of bones and waste, and highest in proportion of extra-edible parts and edible fat. In the two latter cases, of course, the size of the animal must be taken into consideration when comparing swine with cattle.

DOURINE IN FRANCE.

Schneider and Buffard maintain that in France dourine appears nearly every year in the Department of Basses-Pyrenees on the Spanish frontier. It is stated that mares get infected by the asses or horses by which they are covered. It is the custom to have a mare first covered by an ass, and if not impregnated she is then covered by a stallion. The asses operate on both sides of the frontier, and in this way introduce the disease into France from Spain, where it has been known to occur for years, especially in Navarre.

CREOSOTE IN SHEEP DIPPING.

An investigation into the effect upon the composition of coal-tar creosote baths, caused by the passage of sheep through such baths, has been continued from the previous year. It was proved that as dipping is continued, the percentage of cresylic acid contained in such baths becomes progressively less. It is probable, therefore, that as sheep pass through such baths their wool to a certain extent plays the part of a strainer, and mechanically removes from the emulsion an undue proportion of globules of oil and cresylic acid.

Of the animals which gave a positive reaction to tuberculin, 99·15 per cent. showed lesions of tuberculosis at autopsy.

F. E. P.

WEST OF SCOTLAND VETERINARY MEDICAL ASSOCIATION.

A meeting was held in the Glasgow Veterinary College on Wednesday, 22nd October, 1913, at 4.15 p.m. The President, Professor John R. McCall, in the chair. The following gentlemen were present: Messrs. Thomas A. Douglas, W. Robertson, John Taylor, Peter MacIntyre, J. G. MacGregor, Hugh Begg, W. McMurrich, David Brown, W. Ferguson, James McDougall, T. B. Hamilton, Geo. W. Weir, Robert Mitchell, Jun., Wm. Roy, Jas. Macfarlane, Jas. F. Taylor, John Baird, Wm. Watt, Jno. P. Small (Clones, Ireland), H. Gillmor, J. D. Fulton, Duncan MacLeod, P. J. Turner, J. B. Taylor, Jno. F. McIntyre.

Apologies for absence were read from Principal Bradley, Edinburgh, and Mr. Jas. G. Reynard.

The minutes of the last meeting were read and approved.

New Members.—Mr. JOHN BAIRD, Dumfries; Mr. CHADWICK, Falkirk; and Mr. CRAIG, East Kilbride, were proposed by the President, and seconded by Mr. H. Begg.

Mr. JAS. F. TAYLOR, Cathkin, and Mr. MCGEOCH, SENR., Paisley, were proposed by Mr. Hugh Begg, and seconded by Mr. Thos. A. Douglas.

THE INTERNATIONAL VETERINARY CONGRESS, 1914.

The PRESIDENT introduced the subject of the Association's donation, and as there was considerable diversity of opinion as to the amount, the matter was put to the vote whether a sum of six guineas, proposed by Mr. Hugh Begg, and seconded by Mr. James McDougall, or a lump sum of ten pounds, proposed by Mr. Jas. Macfarlane, and seconded by Mr. Robt. Mitchell, Jun., should be decided upon. Nine members voted for the six guineas, and six for the ten pounds. The private subscription list sent round to the members on behalf of the Congress amounted to thirty-four pounds, thirteen shillings; this, together with six guineas from the Association's funds (four guineas of which has already been forwarded), amounted to forty pounds, nineteen shillings.

Other business was then disposed of.

PRESIDENTIAL ADDRESS.

Professor JOHN R. MCCALL.

The PRESIDENT thanked the members for the honour they had conferred upon him in calling him to the chair. He assured them it would be his earnest endeavour to fulfil the duties of the office to the best of his ability, and he would do his utmost to further the interests of the members in every possible way. (Applause.)

The present time was a momentous one for the veterinary profession. Many changes were in the air, and never before in their history had there been more need for interchange of ideas amongst their members, and for the exercise of the spirit of co-operation; and he need hardly add that it was in the harmonious and sociable meetings of societies such as theirs that most benefit could be derived, from deliberations which bore directly upon their calling.

He knew full well there were several members there who held and had expressed the opinion that the future was dark indeed—that motor traction had largely replaced horse traffic, that the good old days were gone never to return, and if they escaped the workhouse they were lucky. Well, with these pessimists he could not agree. Their forefathers had preached the same doctrine, and probably their children would in the future do likewise. They must not lose sight of the fundamental law of compensation that bulked so largely in the history of the world's progress. He admitted that motor traffic had materially affected the incomes of the city practitioner, and to a lesser degree the country practitioner also, but, on the other hand, an enormous field of public health work was daily increasing, and must claim a large number of their graduates in the immediate future. When they remembered that this applied not only to their native country, but to their huge dependencies beyond the seas, where many epidemics were prevalent, they must realise that there was work on which to concentrate their energies, and work which was bound to bring their profession very prominently before the public, and incidentally to increase their social status. (Applause.)

The new Tuberculosis Order would devolve work of an onerous and responsible nature upon many of them, and would of necessity demonstrate the important part they were bound to play in the preservation of one of the chief assets of the nation, viz., public health. There were many other contagious diseases that must ere long be scheduled, and he need only refer to contagious abortion, John's disease, and diseases of sheep. The latter, up to the present, had practically been neglected for want of State assistance, and were annually a source of enormous loss to the agricultural community. It was questionable whether the loss from contagious abortion, directly and indirectly, did not equal the loss from tuberculosis, and it had been estimated that the annual

loss from braxy in Argyllshire alone amounted to between £60,000 and £90,000. It must be evident to all of them that in the days to come, their energies would be largely centered upon the prevention of disease, but at the same time, while they had live stock, there would always be ailments and incidental diseases, which were bound to keep the general practitioner employed.

The breeding of all classes of live stock was never so active as at present, and if they could draw any deductions from the prices being realised for pedigreed animals, it must be obvious that the future in this respect held great promise. Great Britain was the premier breeding country of the world, and although for many years large numbers of animals of most fashionable blood had been exported, the climate and conditions in other countries apparently did not favour the retention of the various breed characteristics, and the foreigners were forced to return to the old country for pure blood stock. Hence it followed that if home bred stock were becoming so much more valuable, it would be to the interest of stock breeders to employ efficient veterinary attendants.

The President then went on to refer to the decrease in students during recent years, and mentioned that many of those qualifying were seeking employment in the Government service and the Army. He expressed satisfaction at the fact that both the Scottish Colleges were now participating in grants under the Scotch Educational Department and the Board of Agriculture for Scotland.

THE TUBERCULOSIS ORDER, 1913.

Mr. THOMAS A. DOUGLAS, Kilmarnock, opened a discussion as follows:—

"It was with considerable diffidence that I consented to open this discussion on the Tuberculosis Order, at the request of our President. So much has been said and written about this Order during the past six months that the subject is almost threadbare, yet possibly after six months experience in the working of the Order, some new ideas may have come to light which may prove of interest, and be helpful both to those of us who are inspectors and those who are private practitioners.

It would be about twenty years since in meetings like this, when bovine tuberculosis was under discussion, the proposal for State control of the disease was advocated first, but it was obvious that the usual methods of stamping out were inapplicable in this case owing to the dislocation of the cattle industry that would follow any such drastic measures. The Board of Agriculture have now decided to tackle the question, and we have the first fruits of this decision in the Tuberculosis Order of 1913.

The Order is a very gentle beginning with a very big problem. The object is, briefly, to get rid of what they believe to be the two most dangerous classes of tuberculous animals, viz., those with the udder affected, and those that are emaciated from the disease.

The first class is not such a very large one, but the damage done by these animals is out of all proportion to their number. The milk from such animals cannot be given to calves without almost certainly producing the disease in them, and that at an age when they are little fitted to withstand such an infection. Although this is primarily an Order dealing with the disease amongst cattle, its bearing on public health is too great to be overlooked; the grave danger to children from tuberculous milk is now almost universally admitted, and, after what Dr. Davies told us at Hamilton the other day, of his experience in this matter, I think you will agree with me that it should be our earnest endeavour to hasten the ridding of our herds of cows with tuberculous udder, both for the sake of the farmer and for the public welfare.

The other class dealt with in the Order, the "piners" or "wasters" as they are commonly called, these will always form the majority of the cases to be dealt with.

There are several indications in the Order, and in the circular letters which were issued to the local authorities with the Order, that this is only a temporary measure, in fact five years is mentioned, and I believe alterations and amendments will be made even before that.

One of the most urgent alterations is the extension of the Order to deal not only with "piners," but also with clinical cases—animals which we believe to be spreading the disease. We know that the location of the lesions determines largely the extent of emaciation; we have seen cases emaciated from tuberculosis in which possibly no tubercle bacilli were escaping from the body, and, conversely, we find animals in quite good condition which, by coughing and otherwise, are spreading the infection all the time.

In the testing of whole herds we have noted that if there is, or has been, a "piner" in the stock, the large majority of the animals in contact are reactors, and in this way I think it is a pity that we cannot remove an animal before it has stood so long in a byre as to have become emaciated, and meantime to have been infecting all its neighbours. Desirable as this extension is, dislocation of the cattle industry of the country must be guarded against.

What the ultimate scheme will be that will deal definitely and fully with this disease I cannot guess, possibly something like the "island scheme" of Professor Delépine, viz., Bang's method in limited areas firstly. But that is outside the present subject, and until we have such a scheme, it is our duty, as veterinary surgeons, to teach the farmers the value of a tubercle-free herd; and to educate the public to the value of tubercle-free milk. The greatest help would be given to the clearing of our herds if the public would give a little more for tubercle-free milk, even $\frac{1}{2}$ d. or a penny per gallon of an increase.

We understand that the Scottish Board of Agriculture have a scheme on hand to assist farmers in the testing of their herds, but it is unfortunately at present in abeyance.

In the course of discussion the question has come up—"What is an emaciated animal within the meaning of this Order?" Our own idea is that if we find an animal obviously lean and in poorer condition than its neighbours, kept under the same conditions, and we believe this condition to be due to tuberculosis, then we would deal with the animal as suffering from tuberculosis with emaciation.

The valuation regulations have come in for some adverse criticism at previous meetings, a dual valuation being in many cases a difficult task, and a liberal single valuation would certainly have been better.

With emaciated animals they can really only have one value; the animal is suffering from some chronic disease or other, and no matter what it is, her value at this time bears little relation to what the disease is which the animal is emaciated from.

In the case of a bad udder it is rather difficult. You can say, "If this cow had a healthy udder she would be worth so much, but if, as I believe, this udder is tuberculous, then she is worth so much less." But the question arises what is the real difference in the two values, a quarter deficient in milk from any cause reduces the value.

Diagnosis is a question of some moment, and deserves a word in passing; the utmost care is required to safeguard both the owners and the public purse—as well as ourselves—and all the aids we can call on should be used.

Microscopical examination of milk, abnormal dis-

charges, etc., should be done as frequently as possible. This work becomes most interesting, and the time taken is well spent from an educational point of view, apart from its bearing on the case in hand.

There are still some people who have no faith in the tuberculin test, but I believe if you get a reaction in an animal tested under its usual conditions with reliable tuberculin, that animal is affected with tuberculosis. One interesting fact has been impressed upon us in the testing of "piners," and that is that the reaction begins early and passes over quickly. This has been so obvious to us that we now inject the tuberculin in the early morning in the case of "piners" and get the reaction during the day. We have found the temperature rise four degrees within six hours, and within twelve hours after injection the temperature is normal and the usual evidences of a reaction have disappeared. It has been said, and is widely accepted as fact, that a preliminary dose of tuberculin to a reactor will interfere with the test; we have not found this to be so, and on a recent occasion we tested a cow on two successive days and got a similar reaction each time.

As to tuberculin, I don't suppose I need tell this meeting that all that is sold as tuberculin is not reliable.

The diagnosing of cases under the Order affords a finer training in diagnosis than anything that has previously fallen to our lot; here you have an animal to examine, and within a few days you have an opportunity of examining the lesions you have located when the animal was alive. This training, if taken advantage of, should prove of great value when we get those clinical cases included in the Order.

The provision for an owner to nominate a veterinary surgeon to make the post-mortem examination might prove a decided hardship to an inspector, and we think might with advantage be deleted, and the corresponding provisions of the Glanders Order introduced, in which an owner or his veterinary surgeon can be present at the post-mortem examination, and if they see fit, object to the inspector's opinion, and the question is then referred to the Board to decide. This would safeguard the inspector as well as the owner.

The regulations dealing with suspected animals in markets are practically inoperable. No community is going to pay compensation for animals found in its markets if it can get out of it. Take Glasgow market for example; an Ayrshire farmer sells a cow in Glasgow, and a Lanarkshire farmer is the buyer, if this cow has a tuberculous udder, then Mr. Begg would find her in the course of his inspection and deal with her, but why should Glasgow be saddled with the expense which would have been incurred had she been dealt with during the few hours she was in the Glasgow market. The option of returning an animal to the premises it came from is very unsatisfactory. I am glad to know that the Board has this section under consideration for amendment. A possible solution may be to pay no compensation for affected animals found in markets in all cases where the owner should have suspected the animal himself. With a "piner" it would be obvious to the owner that something was wrong, and also in many cases of tuberculosis of the udder, and reporting them as suspected would safeguard himself and cost him nothing.

The cost of this Order is not going to be such an expensive matter as some people thought, if the number of cases occurring continues as at present. The compensation, of which the Treasury pays half, is the least of it, and I think the local authorities have a decided grievance in that the Treasury is not paying half the cost of administration as well as half the compensation.

As to compensation, we have a few cases in which the salvage has exceeded the amount payable in com-

pensation; this has arisen in this way. According to the Order any emaciated carcase in which tuberculous lesions are found is an advanced case, on which, of course, one-fourth of the value would be paid as compensation. We all know that some animals, emaciated from tuberculosis, have only a few localised lesions involving some vital organs, and when these are removed the carcase itself would be passed by any reasonable meat inspector. Take one of our cases as an example. A cow was suffering from tuberculosis of the larynx, was emaciated, and coughing persistently—obviously a case within the scope of the Order. When she was killed, apart from the larynx only a few tubercles were found in the lymphatic glands of the chest, and the case was quite clear. According to the Order, this was an "advanced case," while the whole carcase was passed as fit for food.

As to our dealings under the Order in our district of Ayrshire, we have now had above forty cases the majority of which have been emaciated animals; five negative cases.

In the early summer all our cases were animals which we had been called to see in our every-day practice, few of the owners having known anything, or at any rate not very much, about the Order. In August our county clerk issued a *résumé* of the Order to all stock-owners, and held meetings at five centres in the county, accompanied by the veterinary inspector of the district in each case, at which the provisions of the Order were explained. This has resulted in quite a number of our later cases having been reported by the owners themselves.

Here, all the work in connection with the Order has been delegated to the veterinary inspectors, so that there is no delay such as has been reported by some inspectors. On receiving a report we usually make our first visit at milking time, when the cows can be conveniently examined, and in this connection I would advise inspectors to worry the farmers as little as possible; no good can come of adopting an over-bearing manner. Having made a clinical examination of the reported animals, and of others we may suspect, arrangements are made for testing, or a sample of milk is taken for examination.

The valuation is a mutual arrangement between the owner and ourselves, and so far we have had no occasion to call in a valuer, in many cases, in fact, the matter has been left in our hands. Our diseased valuations for emaciated animals have ranged from four pounds in cases of a young heifer to twelve pounds for a pedigreed cow.

In positive cases, having examined the milk or tested the animal with tuberculin, we serve the notice of intended slaughter on behalf of the local authority.

We have all our animals killed in Kilmarnock slaughterhouse, usually removed by float by the butcher who has taken all our cases. Having made the post-mortem examination, the necessary certificate is given to the owner, and we pay the compensation due. Having got his receipt, our papers are now completed and sent to the local authority. I have here copies of the forms we use, if they are of interest to any of you.

With this way of dealing with the cases there is no waste of time; not more than three days at the most elapsing between the animal being reported and the death of the animal. The average nett compensation in the cases dealt with has worked out at about thirty shillings.

Now, gentlemen, you have been very patient; I am afraid I have wandered at times from the Tuberculosis Order, but I trust I have raised some points in connection with it, which will promote a useful and interesting discussion.

The after discussion was joined in by Mr. Peter McIntyre, Greenock, who desired to thank Mr. Douglas for his opening discussion, but differed from him as to an emaciated carcase being passed as fit for food.

Mr. JOHN TAYLOR, Cathkin, congratulated Mr. Douglas, and said that all private practitioners welcomed the Order. While he considered it to be a step in the right direction, he spoke of the difficulties affecting the general practitioner in the carrying out of the Order, and cited a case of emaciation which he reported: the animal was tested and the milk, etc., examined, result negative, still, when the cow was slaughtered the carcase showed generalised tuberculosis. He was also of opinion that one could not say when an indurated udder was tuberculous or not. In such a case he suggested that the veterinary inspector get a sample of the milk to examine and report result to the veterinary attendant.

Mr. HUGH BEGG said he scarcely agreed with Mr. Douglas when he spoke of tuberculous mammitis as being nodular in character. His experience was that the lesion was often single and whether large or small, had an irregular outline, was incompressibly hard or fibrous, and painless, and had no band of connection to the skin, such as is met with in the induration that is left from other infections that have given rise to abscess formation.

The PRESIDENT thanked Mr. Douglas for the able manner in which he had opened the discussion, and proposed a hearty vote of thanks, which was cordially responded to.

On the proposal of Mr. Begg, the discussion was adjourned.

A cordial vote of thanks was accorded to the President, who afterwards entertained the members to dinner in Brown's, Ltd., St. Vincent Street, where a most enjoyable evening was spent.

JNO. F. MCINTYRE, Hon. Sec.

Anthrax at Bradford.

An inquest on the body of Henry Wilson, 42, carding jobber, of Stirling Street, Bradford, was held by the Bradford City Coroner. Wilson was found dead in bed and a post-mortem examination showed that death was due to generalised anthrax.

It was stated in evidence that until October 2 he had been working at a wool-combing shed at Shipley, and he lodged with a man named Heald, who was employed at some other wool-combing works. They slept together and in the shirts in which they worked.

Dr. Eurich, bacteriologist to the Bradford anthrax investigation, said that Wilson could not have had anthrax germs in his blood when he left work on Oct. 2. The maximum duration of anthrax was five days. Wilson might have had it in his clothing and inhaled it, or he might have inhaled it from the clothing of his fellow lodger, Heald. He might have had infection in his own shirt after he left off working, for the bacilli lived for 20 years.

The jury returned a verdict that "Wilson had died from anthrax, but that there was no evidence to show where, or in what circumstances, he had contracted the disease."

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Nov. 10, 1913
NOTE.—The figures for the Current Year are approximate only.

The Treatment of Anthrax.

Good work that has been done all over the West Riding by the Anthrax Investigation Board for Bradford and District, whose annual reports are the best authority on the subject, deserves careful study. For example, in the year ended October 31st, 1912, 1,258 samples of wool, mohair, etc., were tested for the presence of anthrax spores, and 84 gave a positive result. Twenty-three firms co-operated in the sending of samples.

The chief risk of infection is in "skin van mohair," Turkey and Cape Mohair, and Persian wools. Blood-clots and blood-stains are the great carriers of the infection; they are "a danger-signal of the first importance"; but in the last year it has been found possible to cultivate the anthrax bacillus from materials free of any trace of blood. "This seems to have made the problems before the board more difficult of solution." Experiments are continuously being made with germicides and disinfectants—steam, hydrochloric acid and sodium chloride, formalin, cyllin, etc.—but the difficulty still remains how to ensure perfect and practicable disinfection of thousands of tons of material without injury to the material. Incessant care is taken to protect and instruct the workers; but with an industry so vast it is inevitable that cases of infection should occur. In seven years (1905-1912) the board has been notified of 88 cases. The number of cases notified last year was 18, of whom five died.

Sclavo's serum treatment has been in use about 12 years. The old treatment was to excise the place of infection, and to fight the poison with stimulants, quinine, and so forth. But excision was not always possible; for instance, the place of infection might be on the face. Sclavo's serum treatment has almost or quite done away with the need of excision. It is not a perfect treatment; no serum treatment, not even diphtheria-antitoxin, is perfect; still, there is no room for doubt that it is of very great value. Sclavo himself has published two sets of anthrax cases thus treated—one set of 67 cases with two deaths; the other set of 164 cases with ten deaths. (See Dr. Legge's Milroy Lectures on Anthrax, 1905). Dr. Eurich, who as bacteriologist to the Bradford Board, has seen more cases of anthrax in a year than most doctors see in a lifetime, has notes of 85 cases treated with Sclavo's serum, and is convinced "that a greater number of very severe cases recover under the administration than did before we used the serum here."

Salvarsan has been used in anthrax with success by Becker, Bettmann, and Laubenheimer; and in these three cases it had what we may call "a fair chance." In two other cases, where the patient was already dying, it failed, though in one of them there was for a short time a marked improvement. In the case recently reported there is evidence that the patient's previous health had not been thoroughly sound; that the disease was rapidly gaining ground in spite of the serum treatment; and that salvarsan offered the only hope of saving his life.—*The Times*.

The Dinner to Sir T. Elliott.

On Wednesday evening, Nov. 5th Sir Thomas Elliott, for twenty-one years Secretary to the Board of Agriculture, and prominent in many national and international agricultural movements within that period, was the special guest of the Royal Agricultural Society of England, at a dinner held at the Hotel Cecil, under the presidency of the Earl of Northbrook. Amongst the company were: Mr. Henry Chaplin, M.P. (under whose régime as first President of the Board of Agriculture Sir Thomas Elliott was appointed), the Duke of Devonshire, the Earl of Lichfield, Lord Barnard (Chairman of

the Central Chamber of Agriculture), Lord Blyth, Lord Lucas, Lord Morton, Sir Ailwyn Fellowes, Sir John Cotterell, Bart., Sir Gilbert Greenall, Bart., Sir J. B. Bowen-Jones, Bart., Sir Henry Wiggin, Bart., Mr. Alex. E. Parker, Mr. Ed. G. Strutt, Mr. H. L. C. Brassey, M.P., Mr. W. Anker Simmons (Chairman, Farmers' Club), Mr. Charles Bathurst, M.P., Sir John M'Fadyean, Dr. Voelcker, Mr. W. Harrison, Prof. Penberthy, Mr. A. A. H. Matthews (Secretary, Central Chamber of Agriculture), Prof. J. McCall, Mr. Thomas McRow (Secretary, R.A.S.E.), and others.

Mr. CHAPLIN, in proposing the toast of the evening, said that twenty-one years ago, after he had been appointed as the first President of the newly-created Board of Agriculture, it was his privilege to appoint Sir Thomas Elliott to the charge of that great Department. When he became acquainted with their guest he was private secretary to Mr. Ritchie at the Local Government Board. On one occasion, being called on by the late Mr. W. H. Smith to speak on a subject of which, as he protested at the time, he was extraordinarily ignorant, his leader said, "Send for Elliott, he will tell you all about it." He did so, and he believed he made an excellent speech. (Laughter). But when the time came for the Board of Agriculture to be re-constituted, he said, "There is the man," and Sir Thomas Elliott had worked with such success that the Board now occupied a high position in the regard of agriculturists. Mr. Chaplin referred to the valuable services of the guest of the evening in stamping-out the outbreak of foot-and-mouth disease while he was President of the Board, and said he wished to acknowledge the inestimable assistance he himself received from Sir Thomas Elliott while he was head of the Department.

Sir THOMAS ELLIOTT, in reply, said at the time of his appointment the Board of Agriculture was not particularly wanted by anybody. Certainly the Treasury did not want it. It looked upon it as a potential spendthrift, and all his chiefs had great struggles with it. He was not quite sure that agriculturists themselves wanted it. They were all polite, but they were suspicious. He decided that the first necessity was to command the confidence of agriculturists. They aimed at showing that the Board only wanted to do what agriculturists could not do for themselves—to bring pressure upon agriculturists in those things on which the great majority were agreed, and, above all, to remove the idea that they could teach agriculturists their business. He did not think they had been altogether unsuccessful in these aims. Now the old order was changing, and it was very possible that the Department might be merged into a much larger institution, and he recognised that it was not inappropriate that his connection with the Board should be terminated when it did. But, whatever might be in store for them, he would always remember with pleasure that he was one of the small band of workers who established the Department on a firm basis, and who had gained for it, as he believed, the confidence and good will of the great majority of agriculturists.

Clydesdales in the United States.

A correspondent in U.S.A. of *The Scottish Farmer* writing of the Washington State Fair held at North Yakima, says:—

"Mr. Wilson's expressed opinion for the Clydesdale to myself and company, is about all that is poor in the horse line. He had two colts that looked to me a very bad sample of their race, and yet he told us that one of them was fourth in its class (in the hands of Alec Galbraith) at the Chicago International, and that either of them was better than anything he had seen when

over in the old country three years ago. That being so, the old country stock must be in rather bad shape. He went on to state that over there they cared nothing if they had the feet, the legs, and the action; that they forgot all about the top line and the weight, and that from his view-point the Shire was far superior, as he could sell it here, whereas the Clydesdale was not wanted. This despite the fact that he was a Scot and that he got it hot from many friends for going back on the Clydesdale.

The Docking of Horses—Statutory Cruelty to Animals.

At the Marylebone Police Court on Wednesday, Oct. 29th, Jesse Godliman, a carman, of Park Road Mews, Carlton Vale, Kilburn, was summoned before Mr. Paul Taylor, at the instance of the Royal Society for the Prevention of Cruelty to Animals, for unreasonably causing unnecessary suffering to a horse by docking its tail.

Mr. S. G. Polhill, solicitor, prosecuted; and Mr. H. Pierron, solicitor, defended.

Mr. Polhill said that the horse in question came into the possession of the defendant in July, and was worked with its tail entire. He then took it into his head to dock the animal, and cut some inches off the tail. The wound became in a bad state, and it was contended that it was not properly attended to. The only defence offered was that the animal was in the habit of getting its tail over the reins. As regards the docking of horses, it was, he said, a mere fashion, as it was thought that a short tail looked better.

An inspector of the Royal Society for the Prevention of Cruelty to Animals gave evidence in support of Mr. Polhill's statement.

Mr. Alexander Piesse, veterinary surgeon to the Society, stated that when he examined the animal about two weeks after the operation, the end of the tail was granulating and suppurating, there was proud flesh all round it, and about half an inch of bone was protruding. He did not think there was any reason for the docking of horses under any circumstances. In this instance it was simply done to fit the animal for the cart, instead of the cart for the horse. Means could easily be taken to prevent the reins getting under the horse's tail. The operation involved the cutting of four nerves, six arteries, six veins, seven muscles, and the skin, and the searing of the flesh must therefore cause very great pain.

In cross-examination, the witness said that searing was the method invariably adopted in docking, even by veterinary surgeons, but it could be avoided by tying up the arteries.

Answering the Magistrate, the witness said that the operation was performed by persons other than veterinary surgeons, and that any butcher could operate, whether he possessed any skill or not.

Mr. Pierron, for the defence, contended that the operation was necessary, that it was properly carried out, and was, in fact, a correct thing to do.

The defendant said that the animal had a particularly long tail, and he took off three to four inches because every time the tail touched the cart or got entangled with the reins the horse kicked and bolted. Since then it had ceased to do either.

Mr. W. Cawthorne, veterinary surgeon, of Harlesden, said that the horse's tail was properly docked. Although he was against docking as a habit, he thought it was necessary in certain cases such as this.

Mr. Paul Taylor said that this summons was governed by the case of *Ford v. Wiley*, where it was laid down that the operation was not cruelty if it were necessary and for the horse's benefit. In those circumstances he was bound to hold that the operation in this case was of

such a character as not to bring it within the statute. Coming to the operation itself, he formed the opinion that it had not been rightly performed, and that no unskilled person could properly apply the searing iron without causing unnecessary suffering. He fined the defendant 20s., and in view of the general practice of docking, absolved him of any personal discredit.—*The Times*.

Alleged "Overstocked" Cows at Chester. Appeal Allowed.

On Friday, October 24th, at Chester Quarter Sessions, before the Recorder (Sir Horatio Lloyd), Thomas Keenan, cattle dealer, of Newry, County Down, Ireland, appealed against a conviction by the City Justices on a summons by the Royal Society for the Prevention of Cruelty to Animals for unlawfully causing unnecessary suffering to six cows, by causing them to be overstocked with milk.

Mr. T. Artemus Jones (instructed by Mr. T. Moore Dutton) appeared on behalf of the respondents, and Mr. Trevor Lloyd and Mr. T. H. Parry, M.P., (instructed by Mr. R. T. Morgan), represented the appellant.

Mr. Artemus Jones explained the practice followed by some cattle dealers of leaving cattle unmilked in order that they might have a good appearance. It was admitted by everybody concerned that a certain amount of stocking (*i.e.*, letting milk remain in the udder of the cow) was a practice which might not entail suffering, provided it was not carried to an unreasonable extent, and the point which was raised in this case was as to where this reasonable limit was going to be drawn. It was admitted by Mr. Keenan in the court below that in Ireland he milked his cattle twice a day; that was to say that the udders were relieved of their milk every twelve hours. Beyond the twelve hours, undoubtedly, if the udder remained unmilked it entailed discomfort. Beyond the discomfort stage, there was the stage where discomfort merged into the region of pain; and the case for the respondents was that on the facts admitted even by Mr. Keenan, to allow the six cows to remain unmilked for 19 hours resulted in causing unnecessary pain to the animals.

EVIDENCE FOR RESPONDENTS.

Edward Backhouse, Inspector of the R.S.P.C.A., in corroborating counsel's statement, said the practice of overstocking had been pretty general in late years.

Counsel: Is it a practice to allow the milk to remain in the udder, so as to give a cow the appearance of a prolific milker?—It is, to deceive.

In the case of these cattle, would you say it was normal stocking or overstocking?—I should say it was overstocking. All the cows, in my opinion, were suffering pain due to overstocking, and especially two.

In answer to Mr. Artemus Jones' further questions, witness said all the cows were suffering pain, due to overstocking, and especially in regard to two of them—the red and the light roan cows.

Counsel: Did you remain near the cows from the first time you spoke to Keenan to the time when they were milked?—Yes, the greatest distance I was away would be about twelve yards.

At that time could you see whether anybody examined them at all?—No one touched the cows from the time I first examined them until they were milked. Regarding the age of the cows, in his opinion they had all calved from three to seven days, and they would be three to three and a half years.

Cross-examined: He would be very much surprised to hear that two cows had not calved at all. He saw Mr. Storrar, the veterinary surgeon, there, but he did not examine the cows in his presence. Speaking of the

substance which came from the teats on to his hands, he said he threw it to the ground when he was told it was dirt, and he admitted he ought to have kept some of it. Twelve hours was a period quite long enough between the milking of cows. Cows might go sixteen hours without milking, and not suffer from overstocking. Witness then produced his notes and books, and in answer to counsel said he had warned Keenan on no less than six occasions for the same thing—overstocking.

Re-examined, witness said that at agricultural shows arrangements were made by which cattle could be milked there. As a rule they were very careful at shows about this matter.

P.C. Bailey, who saw the cattle at the market, bore out the Inspector's evidence as to the condition of the udders.

Professor G. H. Wooldridge, one of the professors and lecturers at the Royal Veterinary College, and formerly a professor in the Royal Agricultural College, said the description he had heard of the condition of the udders of the cows led him to the opinion that the condition must have been painful at the time they were examined. The normal period between milking was twelve hours. Overstocking caused a cow decided pain, of which there were certain definite symptoms, which he described.

Mr. James Laithwood, Chief Veterinary Inspector for Cheshire, and a large dairy farmer at Congleton, said he agreed generally with Professor Wooldridge's evidence. A period of 19 hours was unusually long for a newly milked cow to remain unmilked, and caused suffering to the animal. Irrespective of the age of a cow and its individual characteristics, there were certain well-recognised symptoms of pain endured by cows when they were overstocked. After 15 or 16 hours the discomfort of the animal became pain. He thought there were arrangements by which cattle could be milked at the Chester cattle market.

Mr. F. G. Edwards, veterinary surgeon, Chester, agreed with the conclusions of the other witnesses.

APPELLANT'S EVIDENCE.

Thomas Keenan, the appellant, said he brought hundreds of cattle from Ireland every week, and came to Chester weekly. He was with these six cows all the time, and in his opinion there was no pain. Four of them only had calved. One cow was foot-sore, but there was nothing the matter with any of the other cows. He had been coming to the Chester fair for 18 or 20 years, and Inspector Backhouse had complained about twice to him, and he had eased them to please the Inspector.

Cross-examined by Mr. Artemus Jones, witness said some cows were overstocked in order to get good prices. He had never heard of such a practice as stopping up teats, until this case. He had never seen a cow overstocked. He paid Mr. Storrar to see that the cows were not overstocked at the fair.

Peter Henshall, farmer, of Knutsford, who bought the cows, said he was perfectly satisfied with his purchase. When he bought them he did not think they were in pain, or overstocked.

Cross-examined: They did not judge entirely by the fullness of the "bag." If he were selling a cow he would milk it the day before.

Counsel: So that it would have a "good bag?"—Yes.

Witness said he had seen a cow "over-bagged" or "overstocked." He did not think "paddling" was one of the signs. If "over-bagged" a cow's hair stood up. "Have you ever seen a cat going for a dog?" asked witness, to see if counsel understood. The laughter drowned Mr. Artemus Jones' answer.

Replying to Mr. Trevor Lloyd, witness said that what the Inspector took from the teat of the red cow, and what had been referred to as "dirt," was wax which springs from the cow owing to her uncalved condition.

Alfred Gosmore, pig dealer, said he saw the cows milked at 3 o'clock the day before the fair.

Patrick Keenan said he saw the cows at the fair at 10 a.m., and they were not overstocked.

James Storrar, M.R.C.V.S., Inspector under the Board of Agriculture, and a practical farmer of 17 years' standing, said he bought cows frequently. He had attended every fair at Chester for the last twelve months. He was there for the purpose of advising farmers and seeing that their animals were properly treated. They came to him as a deputation, and said they were so humbugged by the interference of Inspector Backhouse that they asked witness to come and see the cattle. On this day he saw these six cows and he examined four. Two had calved and two had not. The roan cow was foot-sore. He examined the bags individually, and thought the roan was a bit lame. To be quite sure he ordered a man to "strip" her, and this was done in his presence. There was nothing in their condition to make him think they were in pain. They were all good cows, perfectly healthy; they were chewing the cud and looked quite happy and comfortable. After they changed hands the cows were milked and taken to the station. Cows were usually happy when they were chewing the cud. A cow would eat when it was ill, but would not chew the cud.

Cross-examined by Mr. Jones, witness said he could not say that he had ever seen a cow really overstocked. He was employed by the Irish dealers in the Chester market. He had never given evidence for the Irish dealers before. On that day he examined about 50 cows at the fair on behalf of Irish dealers.

Mr. Stafford Jackson, veterinary surgeon, Liverpool, said in his opinion the cows were not overstocked. For that opinion he had three reasons. The first was that the length of time was not sufficient owing to the fact that nature rebelled against overstocking, and the milk was liberated from the teats. The second reason was the cud, which was a most important thing. In the ruminant the cud was the first thing that was lost in sickness, and it was the last thing that was regained in convalescence. It seemed to him to be absurd to say that a cow chewed its cud when suffering pain to such an extent that cruelty was caused. He had never seen such a case. Thirdly, he had heard no evidence that these cows suffered any inconvenience to their udders the next day. In every case of bad stocking he had seen—and he had seen some very bad ones through cattle being detained on the railway—there was always some after-trouble. That was one of the reasons why a dealer had said he would not buy a cow that was overstocked.

Cross-examined: "Paddling" was a symptom of "overstocking," an arched back might be in some cases, not in all. A hard udder would be a symptom, but not necessarily a distended udder. If a cow were in great pain witness would not expect it to chew the cud. He agreed that if the milk were retained in the udder, discomfort would ensue, but when it did, the gland would relieve itself naturally. He agreed that if colloidion were used to block up the teat artificially the gland could not relieve itself. If colloidion had been used to block the teat, it was one of the most brutal cases of cruelty he had known, and he (witness) would not be there.

In reply to Mr. Trevor Lloyd, witness did not believe colloidion had been used in this case. "If it had been colloidion, Backhouse would have had it here. I have known Backhouse for twenty years." (Laughter.)

James Wilson, veterinary surgeon, said he had had considerable experience with dairy cows, and agreed with what Mr. Stafford Jackson had said. If the animals were suffering pain, the practical farmers would have noticed it.

Cross-examined: Witness would expect increased

respiration—the animal blowing—if the animals were in pain through overstocking. His opinion was that if the animals were in pain they would not have been chewing the cud.

Mr. Trevor Lloyd intimated that he had three more veterinary surgeons, but he thought he would take the responsibility of not calling them, and leaving the evidence where it was—unless the court intimated that more evidence was wanted.

His Honour shook his head.

John R. Turton, farmer, Storeton, said in the depth of winter they milked at night about four o'clock, instead of at noon. Witness did not know that this caused any pain or inconvenience to the cows. If he thought so he would alter the times of milking. At the Wirral Show he had been cattle steward for many years, and there they had the pick of the cows in the country. He had seen these cows milked at six o'clock at night in the presence of the stewards, and milked again on the following morning in the presence of the judges at eleven o'clock, and sometimes nearly twelve. He had not known these cows suffer pain through being left to that extent of time.

Richard Jeffs, farmer, said he milked his cattle at five in the morning and one in the afternoon.

John Foster Pickering, another farmer, said he saw these particular cows on the day in question, and advised his son to buy them if he had a chance. He did not see the cows were suffering pain. They were perfectly comfortable and happy. Cattle did not chew their cud when in pain.

John Minshull, farmer, Mollington, said he knew some of the symptoms of overstocking, but when he heard that the cows were chewing their cud he could not believe they were in pain. A cow in pain would not chew her cud.

THE APPEAL ALLOWED.

In allowing the appeal, the Recorder said there was no evidence to satisfy him that the cows were suffering from the complaint alleged at the time of the sale. On the contrary, there was a large amount of evidence which showed that, so far as outward appearances went, they were in proper condition. He attached importance to the evidence of Mr. Pickering, as one who saw the cows at the market, and advised his son to buy them, and he was a man who had been farming all his life. It was impossible to overlook evidence like that. All the evidence pointed to the same conclusion, that the cows were in a proper condition, and not undergoing any unnecessary suffering.

Mr. Artemus Jones asked the recorder to state a case upon the point that the cows had not been milked for nineteen hours. The Society, he said, were anxious to have the matter definitely settled.

The Recorder declined to state a case, stating that he found there was no unnecessary suffering, whereupon Mr. Artemus Jones said he would have to take other steps.

A Milk Consumer's Complaint.

The following letter was received by the Medical Officer of Health of a large town and handed over to the Veterinary Inspector:—

Dear Sir

I am writing to you about the Milk Supply to S—— will you see in this matter.

Mr. — of — his bringin Milk whare he keep Pig whare he keep Cow and ware he Sile the Milk he ass Pig and it Seem dredfull for I am a Milk consumer but i Shall not By aney more Milk from that farm Til thing his put right and i think that he dose not out to sell Milk in this way.—I am a rat Payer of S.

The Hunting Memorial Fund.

The meeting to inaugurate this Fund was held at 10, Red Lion Square, on Thursday evening. Prof. Macqueen was elected Chairman, and Mr. Henry Gray, Secretary and Treasurer. It was decided to commence by erecting a monument upon Mr. Hunting's grave, and to at once purchase extra ground for that purpose. What further steps will be taken will be decided later—a students' prize competition and an annual lectureship were both suggested as fitting memorials. The General Committee of the Fund was then constituted as follows: The Presidents and Secretaries of all existing Veterinary Societies in England, Scotland, Ireland, Wales, and the Colonies; the Members of Council of the R.C.V.S.; the Principals and Professors of all English, Scotch, Irish, and Colonial Veterinary Schools; all veterinary officers of the Board of Agriculture and of the Department of Agriculture and Technical Instruction of Ireland; all officers of the Army Veterinary Service at home and abroad; and all officers of the Indian Civil Veterinary Department. An Acting Sub-committee—five to form a quorum—was then elected as follows:—Prof. Macqueen, Mr. H. Gray, Sir John McFadyean, Sir Stewart Stockman, Maj.-Genl. Smith, Vet.-Capt. G. Rees-Mogg, and Messrs. R. C. Irving, J. Emerton, Hugh Begg, W. Roger Clarke, Wallis Hoare, H. A. MacCormack, and Prof. G. H. Wooldridge.

The next meeting of the Sub-committee will be on December 12th, 7.30 p.m., at 10 Red Lion Square; and there will be a meeting of the General Committee in January, on the evening of the day of the R.C.V.S. Committee meetings.

The Fund is thus in working order, and Mr. Henry Gray will be pleased to receive subscriptions at 23, Upper Phillimore Place, w. Below is a list of sums already received or promised at this early stage:—

Subscriptions Received up to 7.30 p.m., Nov. 13th, 1913.

	£	s.	d.
Mr. Joseph Emerton, Wandsworth	5	5	0
Henry Gray, Kensington	5	5	0
Granville Gray, Kensington	1	1	0
C. Roberts, Tunbridge Wells	1	1	0
Albert Farrow, Kensington	1	1	0
William Stevens, Westminster Bridge Rd.	1	1	0
Pugh, Buckingham Palace Road		10	6
Marshall, Denmark Hill	1	1	0
Henry Boyer, Paddington	1	1	0
Mulvey, Chelsea	1	1	0
S. W. Pratt, Shanghai, China	1	1	0
Rushie Grey, Royal Vety. College		10	6
	£19	19	0

Subscriptions promised at close of meeting:

Prof. Macqueen	3	3	0
Mr. W. J. Watt, West Brompton	2	2	0
Hugh A. MacCormack	1	1	0
R. C. Irving	10	10	0
W. L. Harrison	1	1	0
Vet.-Capt. G. Rees-Mogg	1	1	0

Foot-and-Mouth in Sussex.

The existence of foot-and-mouth disease among cattle at Street farm, Westham, near Eastbourne, East Sussex, was confirmed on Wednesday.

The Board of Agriculture announce that the usual precautions have been taken to prevent the spread of the disease, and an Order has been issued prohibiting the movement of animals in a large area surrounding the affected farm.

As a precautionary measure the Irish ports have been closed against all cattle from England.

Limitations of the Tuberculosis Order.

At the annual meeting of the Aspatia Agricultural Co-operative Society, Mr. H. THOMPSON, speaking on the new Tuberculosis Order which came into operation on the 1st of May this year, said: Although a step in the right direction it does not go far enough, as it only deals with three forms of the disease. The Order mostly relates to the udder and milk. There is nothing in the Act which empowers the Veterinary Inspector to deal with tubercular disease of the chest—one of the worst forms for spreading the disease—unless the beast be emaciated as well.

Mr. Thompson also gave a good explanation of the methods in use for combating Contagious Abortion, in the course of which he pointed out that abortion in cattle is almost as bad as tuberculosis to the stock breeder and feeders. As a preventive, experiments have been carried on in Oxfordshire from 1911 to 1913. According to the return, there are about 23,824 cows and heifers in that county; 16,390 of these are in milk, and the quantity of milk is estimated to be about 9,014,500 gallons a year, valued at £300,500. Experiments have been carried on in 14 herds, and so far have been considered very successful.

Mr. Thompson's paper was listened to with great interest, and he was thanked at the close.—*The West Cumberland Times*.

Donation to R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following donation to the College funds for 1913:

Mr. Geo. Garnett, Hove, Sussex £1 1

Superstitions.—One of the speakers at the recent meeting of the Central Chamber of Agriculture said he "read the other day that there was a widely-spread idea among farmers that they could avoid abortion in cows by cutting off the cows' tails." He added that "instruction was needed to cure such ideas." Not long since, investigations as to the cause of a smoky chimney in a farmhouse occupied by a farmer who despised superstition, disclosed a couple of bullocks' hearts pierced by dozens of pins—an operation that had been performed to remove a "spell."

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Nov. 11.

REGULAR FORCES. ARMY VETERINARY CORPS.

The following Lieuts. (on probation) are confirmed in their rank:—

H. E. A. L. Irwin, T. J. Davis, J. Going, and F. B. Sneyd.

Personal.

Mr. T. CHAMBERS, M.R.C.V.S., was elected on the 10th inst., for the third time Alderman for the County Borough of Dudley.

Mr. T. DUNLOP YOUNG, Chief Veterinary Officer to the City of London Corporation, arrived in Buenos Ayres by the R.M.S. "Andes" on Tuesday evening, 14th ult. Mr. Young, who is accompanied by Senor del Castillo, the veterinary representative of the Argentine Ministry of Agriculture in London, was met on his arrival by the Director of the Live Stock Depart-

ment, Dr. José Leon Suarez, representing the Minister of Agriculture, and a Secretary from the British Legation. Mr. Dunlop Young has come to this country on the invitation of the Argentine Government to make an inspection of all the details of the conditions under which meat is prepared for export.—*Review of the River Plate*.

OBITUARY

ARTHUR VICTOR WILLIAM SEWELL, M.R.C.V.S., Wickford Essex. Graduated, Lond: Dec., 1902.

The Southwark Coroner, on Friday, 7th inst., opened an inquest concerning the death of Arthur Victor William Sewell, aged 34, a veterinary surgeon, of Wickford, Essex, who was found unconscious on the platform at Mark Lane Station, and died on the way to Guy's Hospital. A bottle labelled "Poison" and a packet of cigarettes soaked in prussic acid were found in his pocket. It was stated that he had no troubles of any kind, but in his pocket was found a letter addressed to his brother, in which he said: "Please forgive me, but I have been through a terrible mental strain."

The inquest was adjourned for the attendance of a medical witness.

Dr. S. Taylor, of Guy's Hospital, whose absence had caused the inquiry to be adjourned, explained that the message from the Coroner's officer was not delivered to him at the hospital until the inquest had been adjourned.

Suicide whilst insane was the verdict on the dead man.—*The Evening News*.

CORRESPONDENCE.

DIAGNOSIS.

Sir,

Under this heading, Mr. Wallis Hoare, in your issue of the 8th inst., replies to a letter of mine which appeared in your issue of the 1st inst.

I am pleased that Mr. Hoare agrees with me that no one has a right to publish an article "in which the writer admits his want of skill in such a manner as to make it appear that necessarily all members of the profession are equally unskilful," but I am sorry that he should consider it necessary to deny that in any article written by him he was guilty of so doing, especially as I avoided making any personal remarks.

I do not accept his pronouncement that, "if I form a definite opinion in a large number of cases, and find that in these cases my opinion is always supported by post-mortem evidence, then indeed I must have exceptional skill in diagnosis." No matter how confident Mr. Hoare may be from his experience, I consider it a calumny to make such a statement *re* the ability of the members of the profession in this matter—that it is exceptional for anyone to diagnose the majority of ailments in cases submitted to him for examination. I have no doubt that most of the members of the profession would consider it an insult to be told that they did not know what the majority of their patients were suffering from, and it is writing in this vein that I consider objectionable, whether it is written in the "first person plural" or otherwise.

I have read many of Mr. Hoare's articles with much pleasure, and gained information from them, but I suppose that so prolific a writer cannot be expected to give to us nothing but the golden grain, and now that he agrees with me I hope that his ready pen will in the future uphold, in no equivocal manner, the ability, integrity, and honour of our profession.—Yours truly,

JAN. MCKENNY.

Dublin. Nov. 11.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1324.

NOVEMBER 22, 1913.

VOL. XXVI.

THE HUNTING MEMORIAL FUND.

Last week we reported the inauguration of this fund, and a subscription list which, though no public appeal has yet been made, fell little short of £40. To-day we publish a second subscription list, and it is possible to add some further information.

At last week's meeting, it was decided to erect a monument upon Mr. Hunting's grave, and to purchase additional ground for that purpose. This purchase has been completed, and the monument will be proceeded with; but this will only require a comparatively small portion of the sum it is hoped will be raised. The major part will be devoted to some veterinary object which will help to preserve the name of William Hunting to future generations of our members—such as the annual lectureship or prize competition which have already been suggested, but the decision will not be made hastily. It cannot well be made until the approximate amount of money which will be available is known; and it will not be made before the profession has had ample opportunities of considering the matter.

The fund will probably remain open till towards the end of next year; and in the meantime all suggestions regarding its application will receive full consideration.

The large Committee which will make the final decision is so thoroughly representative of all sections of the profession that its choice must surely be a suitable one. It is probable that the money will be transferred in trust to the R.C.V.S., for, whatever form the memorial may take, that body will probably be the fittest to administer it.

We wish well to the fund. William Hunting's life and work are still fresh in all our minds; and the profession for which he did so much will welcome this opportunity of perpetuating his memory.

DIAGNOSIS AND CONFIRMATION.

Mr. T. A. Douglas recently pointed out that the Tuberculosis Order "affords a finer training in diagnosis than anything that has previously fallen to our lot." He said "You have an animal to examine, and within a few days you have an opportunity of examining the lesions you have located when the animal was alive." This is quite correct; and a veterinary inspector working carefully and keeping notes might succeed in advancing our knowledge of the clinical diagnosis of tuberculosis. We note the point as a suggestion to clinicians. It is one of those chances of carrying on research in daily practice that are more common in our work than some men realise.

YEW POISONING.

W. R. DAVIS, M.R.C.V.S., Enfield.

Most of the cases of poisoning by yew that I remember to have seen recorded are described as having run a rapidly fatal course. Six years ago I myself saw a horse die a few hours after eating yew twigs, it in fact died in the road very soon after being taken out of harness. Every animal poisoned by yew, however, does not succumb quickly.

Recently I had a telephone message at night requesting my attendance next day to advise about a Jersey cow that was reported as not seeming well. As I did not deem the case urgent, I put off the call until the afternoon. At mid-day I had an urgent call to come at once, and on arrival found the cow dead.

I was informed that up to the previous morning the cow was alright, when she appeared to be dull refused food, ceased to ruminate, and gave much less milk than usual, and had slight diarrhoea. She remained in this condition all that day and up to nearly mid-day of the day she died. The cow was then found going round the box, staggering, holding the head low, shaking the head, and pushing with it against the walls. There was some salivation and grinding of the teeth. After the onset of these symptoms, the cow lived about a couple of hours. I suspected some acrid narcotic poison, but was informed that there were no poisonous plants in the field where she had been at pasture, and particularly that there was no yew.

I made a post-mortem, and as a result of it was convinced that I had to do with vegetable poisoning. A careful examination of the field and the hedges was made, and in the shrubbery next the field some yews were found, and a break in the fence showed where the cow had got to one of them. I am glad that I did not attend on the previous evening or on the morning of the cow's death. I hardly know how I should have diagnosed the case then.

There are two poisonous principles in yew toxin, an alkaloid with a powerful narcotic action and a formic acid-like principle, which produces intense irritation of the digestive mucous membrane. In the case recorded here it looks as though the brain disturbance from which the cow evidently died was delayed until absorption of the toxin was more or less complete, and it was in sufficient quantity in the blood to affect the nerve centres.

EXTENSIVE RUPTURE OF THE STOMACH IN A FOAL.

D. C. GREENE, M.R.C.V.S.

The subject was a cart foal between six and seven months old, which had been running out at grass until two days before the illness, when she was brought in owing to bad weather.

The animal was first noticed to be dull and off her feed on the morning of the 12th inst., and the owner, suspecting a chill, sent for me early in the afternoon.

The symptoms then presented were:—The animal stood with her head hanging down and was disinclined to move, the temperature was 101.7 F., and the pulse did not seem to denote anything very serious; the respirations seemed normal, except that they were very shallow; there was no pain, no sweating, nor any sign of ingesta coming from the nostrils, neither was there any sign of vomition.

The treatment consisted in the administration of sp. etheris nit., with quinine and some linseed oil.

The owner noticed the animal sweating slightly, and occasionally looking round to her sides during the course of the evening, and about three o'clock in the morning she died suddenly.

Post-mortem at 10 a.m. On cutting into the abdomen a quantity of gas escaped from the peritoneal cavity, and on the incision being enlarged, a large quantity of ingesta was seen covering the bowels. This was removed, the amount being estimated at four gallons. The stomach was found to be ruptured along its greater curvature to the extent of quite fourteen inches, and was almost empty.

The case seems worthy of recording owing to the obscure cause, the absence of any symptoms which would lead one to suspect stomach trouble, the extensive rupture, and the enormous amount of ingesta found in the peritoneal cavity.

ABSTRACTS FROM FOREIGN JOURNALS.

THE EARLY STAGES OF BOVINE MAMMARY TUBERCULOSIS.

Zoest and Kracht-Palejoff published last year (*Zeitschr. f. Infektionskr. u.s. w.d. Haustiere*). They carried out researches upon the udders of sixteen cows, all of which animals were affected by general tuberculosis. None of the udders showed any abnormality to the naked eye; but inoculation into guinea-pigs proved the presence of tubercle bacilli in the supra-mammary glands in eight cases—equalling 50 per cent. of the whole. In four of these eight cases—that is, in 25 per cent. of the whole—histological examination demonstrated tuberculous lesions in the halves of the udders appertaining to the supra-mammary glands containing bacilli. From these results the authors draw the highly important conclusion that in general

tuberculosis of cattle an udder tuberculosis is far more frequent than has hitherto been supposed.

After a histological study, the authors divide this early and purely microscopic tuberculosis of the udder into two forms, viz., a disseminated sub-miliary tuberculosis of the inter-alveolar tissue, and a more diffuse tuberculosis of the excretory ducts. In both forms the process begins, not in the epithelium of the cavities of the gland, but in the connective tissue, and probably in connection with capillaries. In both forms, also, the epithelium of the alveoli and excretory ducts is quickly lost at the places adjacent to the tuberculous centres, so that the latter break out into the excretory system. In other words, bovine mammary tuberculosis is a disease with open lesions almost from the beginning of its course; and these lesions may be open before any clinical symptoms appear to cause even a suspicion of tuberculosis.—(*Berliner Tier. Woch.*)

[If these views are well-founded, they are obviously of great importance in the working of our Tuberculosis Order.—*Transl.*]

THE TREATMENT OF TETANUS.

Prof. Schmidt, in a report of the work of the Veterinary High School of Dresden, for the year 1912, compares the results of nine cases of tetanus in the horse. Two were treated with morphia and chloral hydrate alone, and the other seven with tetanus anti-toxin. The two first-named horses were both slaughtered as incurable, one after 12 hours and the other after 3½ days of treatment. Of the other seven, one was slaughtered, two died, and four recovered.

The antitoxin was given intravenously, and in large doses. Five horses received 1000 units each, one 900, and one 500. The one treated with 500 units died, and the one treated with 900 units recovered. Of those treated with 1000 units, one died and a second had to be slaughtered, while the others recovered. The periods taken for recovery in the four successful cases were respectively 16, 23, 28, and 33 days.

In Schmidt's view, these results point to the following conclusions. Even when large doses of antitoxin are employed in the treatment of tetanus, they have no especially favourable influence upon the percentage of mortality. But when recovery does take place under large doses of antitoxin, the duration of the illness is sensibly shortened. Under other methods of treatment a period of from six to eight weeks may be expected before the tonic spasms disappear. In these four cases they disappeared in from 16 to 33 days; and the average period required for recovery was exactly 25 days.—(*Münchener Tier. Woch.*)

ECLAMPSIA IN A MARE.

L. Hub, a district veterinary surgeon of Buchloe, records the following case. He was called to a mare which was due to foal in eight or ten days, and which had been for an hour in the most violent convulsions. Before Hub arrived the mare was

brought out of the stable on account of the danger to other horses which her struggles occasioned; and he found her lying upon straw in the meadow. By this time the convulsions had almost ceased, and only now and then the mare showed spasmodic movements of the hind limbs.

A most careful examination revealed nothing abnormal beyond a moderate acceleration of the pulse and respirations. During the whole examination the mare lay apathetically upon the ground as if unconscious, and only when the vagina was explored did she show some convulsive movements of the hind limbs. Hub now attempted to get her up, but failed completely. When raised she collapsed helplessly to the ground again, and lay there with closed eyes almost unconscious.

Although Hub had no great apprehension that premature parturition was imminent, yet it now set in, and a living foal was quickly delivered. The after-birth came away naturally a quarter of an hour later. Cold douches were then applied to the head, and half an hour after parturition the mare raised her head of her own accord, and managed to assume a sitting position. After another half-hour, by the aid of four men, she was brought to her feet and supported back into the stable. Slings were improvised, but these soon become unnecessary, as she was speedily able to stand well.

At first, recovery was rapid. The next day the mare appeared perfectly well and lively, and on the fourth day she was put to light work. Eight days later Hub received the tidings that she was again showing a similar convulsive attack. On his arrival he found her lying in the stall completely covered with sweat, grinding her teeth, and rolling her eyes. As quickly as possible he resorted to cold applications and an injection of morphia, but half-an-hour after his arrival the mare died in convulsions. The post-mortem examination yielded *completely negative results*—*Münchener Tier. Woch.*

W. R. C.

THE STUDY OF LOOSE COMBINATIONS OF OXYGEN IN SOME COLOURED BACTERIA AND FUNGI, K. SHIBATA (*Jahrb. Wiss. Bot.* (Pringsheim, 51 (1912), No. 2, pp. 179-235).

As a result of the author's investigations, carried out with bacteria and other lower forms, the number of bacteria known to bind oxygen loosely was considerably extended. The same capability was found in cases of yeast and of *Monascus purpureus*. The stored oxygen begins to be gradually given off as soon as the pressure of the surrounding oxygen sinks to zero, and this separation continues for a considerable time in an atmosphere such as that of hydrogen, carbon dioxide nitrous oxide or other indifferent gas, as is easily demonstrable by use of aero-kinetic index bacteria. Pure or dilute carbon monoxide displaces the stored oxygen in the bacteria in question. The process is reversed on a sufficient increase of oxygen pressure. The same relation with oxygen is exhibited by some other gases.

The capability of coloured bacteria to store oxygen is retained for some time after the bacteria are killed by moderate heat or by narcotization with ether or chloroform gas. It is not possessed at all, however, by the colourless varieties. The loose combinations of oxygen are modified in characteristic ways by certain oxidizing and reducing agents and by cyanogen.

Parts of various higher plants, containing such colouring matters as carotin or xanthophyll, have been investigated for evidences of such loose oxygen combination, but as yet without positive results. It was found that the bacteria studied were obligate-aerobic, but able to thrive under very slight oxygen pressure. The various bacteria and fungi cultivated in air containing dilute carbon monoxide showed limitation of growth in characteristic ways. This is thought to be attributable to the direct poisonous influence of the carbon monoxide until a very low oxygen tension is reached, when disturbances of respiration set up other marked injurious effects.

It is claimed that the oxygen-binding agents are the lipochrome colouring matters. In case of *Monascus* this process was associated with a colour-change which was studied spectroscopically.

By this method of gas analysis, the separation of loosely combined oxygen was found to be, in general, less than the corresponding change in case of haemoglobin to which it is said to be analogous. These bacteria are said to function as storers, but not as carriers of oxygen.

The biological significance of this storing of oxygen is claimed to be that in case of a temporary exclusion of oxygen, these bacteria can live for a time upon the supply given off from their own colouring matters. These, in this sense, are regulators of oxygen pressure, in a degree removing the aerobic bacteria from the danger of quick oxygen starvation.

SOME DATA ON THE INHERITANCE OF HORNS IN SHEEP.—T. R. ARKELL. (*New Hampshire Sta. Bul.*, 160, pp. 3-35, tables 7, figs. 43).

This contains a review of evidence of other investigators on this topic and a continuation of experimental work, previously noted (*E. S. R.*, 25, p. 373).

In studying inheritance in horns the common measure adopted in comparing size was the ratio of circumference to length. Horns measured every month from birth showed that they reached maturity at about 18 months of age. Tables are given which summarise the various matings that are made, their hypothetical somatic and gametic composition as to horns and other data.

"At three months of age the rams possessed on an average a ratio (length divided by circumference) of in round figures 2, the ewes 1.6; at six months the rams 2.6, and the ewes 2; at one year the rams 3.25, the ewes 2.5; and at 18 months the rams 3.4, and the ewes 2.7. The average ratio of a matured horn, according to our measurements of 48 Dorset horn rams and ewes, was for the ram 3.44 and for the ewe 2.72. Where reciprocal

crosses were made of long horned sheep (Dorset horn) with a hornless sheep (Down), the females were invariably polled and the males always possessed some indications of horn growth, varying all the way from minute scars to a medium-sized horn. The longest horn from such a cross had a ratio of 2.86, and the shortest consisted of a scur with a ratio of 0.32. . . . Matings between hornless sheep invariably produce hornless females, and males that are either hornless or possess intermediate (simplex) horns. The hornless females may be pure or simplex, which selective breeding alone will show, unless their lineage for several generations is known. The hornless males cannot reproduce a horn. . . . The knob condition which seemed to be present only in Merino sheep was found to exist in some cases, without producing a scur or horn, through successive generations. It is thought that the knob represents the duplex condition of the Merino horn, as records show that when crosses with other breeds were made the knob disappeared, the F1 female offspring possessing either an entire absence or a long horn, according to the nature of the mating. When a ewe bearing the knob character was crossed with a long horn ram other than a Merino, the offspring of both ram and ewe possessed a long horn. The length of the horn of the F1 offspring though the ratio of length to circumference was somewhat less than that of the long horns of the Dorsets, clearly entitles the inclusion in the long horn class.

This patently proves that the Merino bearing a knob must possess two horn determiners in her germ plasm; otherwise we should have some hornless females, and males with simplex horns. It further proves that the potent horn determiner of the Dorset is not offset by the weakness of the Merinos, determiner, but rather strengthens it, for the two together are capable of producing a heavy horn almost as large as the pure Dorset horn. The offspring from matings between a hornless ram and a ewe bearing knobs are in every respect similar to a hornless and a long horn sheep; the females show an entire absence of horn growth, and the males bear the usual simplex condition of horns. . . . A peculiar feature of the simplex horn in the offspring arising from the Merino crosses, comprehends a striking irregularity in size between the right and left horns of many individuals. . . .

The wide variation of the simplex horns in the different males is worthy of notice. Apparently the horn determiners and inhibitors do not always exist in equal degrees of strength. The inhibitor at times may so predominate over the single determiner as to reduce somatic appearance of horn growth to a considerable extent. A wide variation was found in simplex horns in Southdown-Dorset crosses. With the exception of the Merino crosses, no extracted females possessed the slightest vestige of horn other than a perfect long one, which shows how completely the single horn determiner is held in abeyance by the double inhibitor.

In the F2 individuals obtained from Merino crosses with hornless sheep, a reappearance of long horns in the rams occurs, although the ratios of

these horns are somewhat less than the average for the horns of Dorsets. The ewes either bear knobs, scabs, or are hornless. The striking dissimilarity between the lengths of the right and left horns of Merinos, especially simplex, is also shown."

F. E. P.

NORTH MIDLAND VETERINARY ASSOCIATION.

The quarterly meeting was held at the Grand Hotel, Leopold Street, Sheffield, on Tuesday, October 21st, the President, F. L. Somerset, Esq., in the chair. Also present: Messrs. J. S. Lloyd, Hon. Sec.; H. Thompson, Sheffield, Hon. Treasurer; G. Green, S. E. Sampson, E. G. Johnson, T. Bowett, T. C. Fletcher, H. P. Lewis, A. D. Morgan, J. Abson, H. R. Laycock, W. Collinson, C. S. Smith, W. Brown, W. Murgatroyd, G. J. Furness, and S. H. Nixon. The visitors present were—Messrs. H. Sumner and H. W. Dawes, junr.

The minutes of the last meeting were read and confirmed: also the report of the Council meeting held on Oct. 7th.

Arising out of the latter the Association decided to affiliate with the Northern Branch of the National Veterinary Medical Association.

The chief matter for consideration was a discussion on "Veterinary Politics," introduced by HENRY SUMNER, Esq., of Liverpool, and as Mr. Sumner had to leave to catch an early train the President immediately called on him to introduce his paper.

VETERINARY POLITICS.

By HENRY SUMNER, F.R.C.V.S., Liverpool.

Gentlemen,—I trust you will excuse my temerity in appearing amongst you to initiate a discussion on the politics of our profession; discussions are now popular, and rightly so, and have been the means of inducing a free expression of opinion; I hope to-night's will in no way fall short of that ideal. There are many matters, in my opinion of supreme importance, upon which as a member of Council I am anxious to learn the sense of the profession.

I claim in our politics there is no "party." Every member of our governing body is animated with one desire—to uphold and advance the best interests of our profession. It is a most conservative body, to which principle I subscribe, realising that the principle must be a progressive one, for without progress we will have little indeed to conserve. At present our reserves are becoming "smaller by degrees and beautifully less."

The first possession to conserve and preserve is our one portal system. Those who have gone before did valiant service in acquiring for us complete protection of our professional entry. Like every form of protection the absence of competition may lead us to a sense of inertia; it is up to our generation to maintain and advance the position gained for us. The cost of that portal is not yet paid and we have had recent evidence that the interests which were then combined have not ceased safeguarding the rights of its licensees; nor has the list of existing practitioners approached a point which can be described as vanishing. In this remark I do not wish to disparage a most useful and generally well conducted group of veterinary practitioners; they have both disabilities and privileges which are not ours.

In regard to the one portal may I say that the University of Liverpool never entertained the idea of licensing for practice. What she has done and is doing is with the desire to advance the dignity of our profession

and open her doors to the admission of students to the veterinary side of medicine.

Not only has the Royal College to guard the portal by examinations and provide the expenses, but our "free" profession has also had the advantage of the individual rights of its licensees being guarded and protected at very considerable cost to the College. Much has been done by recommendation of the Registration Committee; more might have been attempted had funds been available. I fear the members of our body do not sufficiently appreciate the difficulties of that Committee.

It is at times depressing to find evidences that fraternal feeling in those in close quarters is often sadly wanting, and many of the complaints require more evidence than is forthcoming. When such cases are remitted to the complainant for that purpose, they usually "drop out." The practice of the law is akin to ours, and a "lost" case leaves a bad impression, consequently great care is exercised in selecting cases for prosecution. At the present there is much which causes anxiety and requires careful handling.

Further, expensive work of the College to safeguard the rights of its licensees pertains to a careful watching of all Bills relating to animal life and products. It is more than ever apparent that direct Parliamentary representation is desirable, and should be effected at the earliest possible time.

Whilst the V.S. Act (Amendment) Bill falls short of much of its early expectations, it will give further rights and responsibilities to "E. P's." I do not regret the price, it is in our best interests that these practitioners are amenable to the disciplinary powers of the College; further it gives power to deal with an offending company as with an individual.

What then is our position? Is there danger to our possessions? In answer to the first—our position financially leaves much to be desired, we are compelled to liquidate the funds of the College on a falling market to meet absolutely necessary expenses. Such a system must come to an end, and it is estimated that, without greater income, at the present rate of expenditure our funds will have vanished in a period of ten years.

From whence came these funds? From the profits of examining candidates for our licence. This has now ceased to exist through the very serious decline in the numbers seeking our qualification, owing to various circumstances; primarily in the raising of the preliminary examination and extension of curriculum, and secondarily in the fear generated by the coming of mechanical traction that the horse was doomed, and with him veterinary surgeons. We know how fallacious is the latter; the vanishing horse has reduced that side of our work; but the law of adjustment has brought very rapidly and prominently forward the work of the veterinarian in all that pertains to milk production. Hence if we are not to cease to exist, we must have money from somewhere, and while we have enjoyed all the privileges of our licence without cost, I cannot understand any opposition to the Bill now before Parliament to provide funds necessary for our very existence.

So much for what may be called our "domestic" position. What is our position in comparison with holders of one of the licences to practice medicine? In answer, I think all are agreed that our licence is of equal merit to theirs, and as professional men we have an equal standard. We have individuals who, unfortunately, fall below—and so have they.

This brings me to a point of some moment. The medical schools have given notice that after the completion of this year they will require a higher standard for the preliminary examination. Hitherto most of the veterinary students have taken the same examination as students for licence in medical dentistry, etc. I refer to

the examination held by the Educational Institute of Scotland. Due notice of the proposal came before the Council, and after consideration it was decided, in view of the shortage of entrants, that it was undesirable to follow the lead of the General Medical Council, and it was arranged that the Scottish and other bodies would continue to examine our candidates on the present standard. However, it appeared that the change adopted by the General Medical Council was not so serious as at first anticipated; it was a raising of the pass marks together on certain results, allowing the examination to be taken in two parts. The matter was reconsidered, with the result that the Council accepted the recommendations of the Preliminary Examination Committee, and decided that after November, 1914, candidates for our diploma would be required to take an examination equal to that required by the General Medical Council. When this matter came up for confirmation it was referred back to the Committee. This is a question of policy.

Without wishing to add to the difficulties of the candidate, I certainly am of opinion that the veterinary surgeon should continue to be on equal educational footing with those who practice medicine.

Perhaps it will be fitting at this stage to ask for how long shall our portal be closed to women? A short time ago an enquiry was addressed to the College as to the eligibility of women for our diploma, with the resulting answer that the College had no power to admit women to its examinations. This prompted another enquiry from the same source, as to which body the College could direct him in order to acquire the right of women to those qualifications now enjoyed by men. A courteous reply was sent. Courtesy may not suffice, and definite action may become necessary, and it would be well for this meeting to consider carefully the point raised. So far as I am aware, the profession has not given an opinion as to the desirability of admitting women to our qualification. The noted trial in by-gone years was ended in a quibble as to location of the College.

Now as to progress. Notwithstanding the financial difficulties, the College is at present offering to vary and add to the diplomas which it grants. After long and repeated consideration it has decided that the conditions both in the qualifying period and in the examination for the Fellowship diploma should be varied, allowing a qualifying period of two instead of five years a wider range of subjects, encouraging specialised work and the subject for which the diploma is granted to be stated; the eligibility of candidates under the original conditions is for a period which should obviate any disappointment or hardship. In the opinion of the Council the change will add to the dignity of the diploma, and it allows a large field for special work.

It has also been decided to institute a new diploma in V.S.M., which entails a considerable increase in the period of study, that post-graduate diplomas are of importance goes without saying, and with their coming has arrived the time for specialism in our profession.

Power for this progress has to be sought in a new Charter, which has been before the Council. In our present condition it was a desideration that nothing of a contentious nature should be sought; the draft Charter simply seeks additional power for the alteration in the Fellowship and authority for new diploma; there is one further clause to allocate to the new member of Council receiving the lowest number of votes, the position, with its corresponding period of service, of any member who retires from the Council other than by the completion of the period of service to which he was elected. At present the position is allocated by ballot, and the member receiving the highest number of votes at the last election has this year to go again to the poll.

As a result of the findings of the recent Royal Commission on the Veterinary Services, the bye-laws of the College are being altered in order to allow the degree graduates in Science, Arts, and Medicine of any University in the United Kingdom, also licentiate or member of the Royal College of Surgeons and the Royal College of Physicians, a remission of the subjects of the first examination, excepting junior anatomy; the combined portions of anatomy to be taken in the second or B examination. By the vote of Council the remission is confined to those who have acquired the degree, etc., but I hope at no more distant date than twelve months, necessary under the bye-laws, that all those who pass the intermediate examination which includes the subjects may also be permitted the exemption.

As to the general policy of our profession, we cannot live alone, and every member should be associated with a Society of his fellows. The combination of Societies in the National is one which offers great opportunities. Politically, the profession is apathetic. Our last annual meeting of the Royal College was evidence that notwithstanding the very important matters which were proposed and being carried, there was no discussion and no voice raised, for or against. The time may arrive when candidates will be required to state their views on matters professionally political. With the exception of those for and against the Bill, no party cry has of recent years been raised.

Another item in general policy is the necessity of every member doing something to assist in making the coming International Congress a success. Veterinary science neither begins nor ends in this country, and I feel that the great majority of our members fail to appreciate the significance and honour of that body meeting in our country next year. At present the subscriptions to the necessary expenses are confined to a few, but there is still time for the many to come forward and help.

Thanks to the success of veterinary surgeons employed in National and local positions, in the dual capacity of safeguarding both human and animal health, an increasing necessity for such help is apparent, and the relationship between the M.O.H. and the veterinarian is distinctly improving.

In reference to the Schools, all I wish to say is that they require more money for the efficient teaching than it is possible to acquire from the fees paid by students, and that veterinary education has as great a claim on the Government of this country as any other system.

It is not for me to direct discussion; I have dealt with principles of policy, and upon those points I feel I am not alone in desiring guidance from the profession.

DISCUSSION.

The PRESIDENT, in opening the subject for discussion, said: We have listened to Mr. Sumner's address on the very important subject of the politics of the profession to which we belong. In my position to-night it is not at any rate for me to have very much to say on the matters brought before you. That they are of great importance, and that there may be probably more than one opinion on some of them, there can be very little doubt, but in my mind, judging from the inside view which we have been able to get as to the doings and intentions of our governing body, the question of the low financial state of the Royal College, and the question of the establishment of new degrees, stands at something in the relation of "cause and effect." It almost appears as if the Royal College not only had the view that it is to the advantage of the profession, speaking professionally of course, that new degrees should be established, but also they may prove a source of income, and so to some extent stop the very serious depletion of funds which is occurring, and which we have been informed to-night will, in the space of ten

years, unless it is checked, lead to a condition of bankruptcy. I did not notice in the address to which we have listened any reference to the question of an annual fee from any member of the profession. That is a question which has certainly been omitted. Whether we have to take it that the Council has dropped it or not, perhaps we shall hear later on. In my opinion it would not be a hardship to the profession if the members were asked to contribute yearly a fee to the funds of the College, and it is probable that that would be a means of establishing the financial stability of the Royal College. That is perhaps a subject on which an expression of opinion from members present would be advisable. The subject of the address is now open to discussion and I hope that it will be freely ventilated.

Mr. SUMNER here remarked that provision for a proposed annual fee of £1 1s. is still in the Bill to be brought before Parliament.

Mr. ABSON (Sheffield): I do not know how to open the discussion, because Mr. Sumner has covered the ground so completely, and I am so much in accord with all that he has said, that I cannot raise contentious matter. I might refer to this proposed new Fellowship examination. There is no question, but that the old Fellowship examination was obsolete, and it has become absolutely necessary to introduce an examination worthy of the name, and I do not think the Council could continue on the old lines. Then with regard to the Diploma in Veterinary State Medicine, that has been practically thrust upon us. We know that two Universities have been issuing such diplomas—Manchester and Liverpool—and others have threatened to do so. We cannot stand aside; we ought to be the pioneers in these matters. To allow that sort of thing might jeopardise the one-portal system. The President had referred to the question of an annual fee. Of course that is provided for in the Bill, and I think no one will object to contribute to it. The Essayist states that ten years will see the extinction of our funds. I think that is a very liberal allowance, and that seven years would be nearer the mark, and that would mean that the buildings and everything belonging to us in Red Lion Square would go. We are in a predicament, and there is no other means of raising funds than the proposed annual fee. We cannot raise the fees of the students for they are high enough already, and we must look to ourselves to raise the necessary funds to keep us going.

Mr. BROWN (Worksop) strongly objected to women being allowed to enter the profession, and suggested that any who wished to do so should marry veterinary surgeons and assist their husbands in their practices. He said there are two things we have to consider—(1) the Colleges are short of funds owing to lack of students; (2) The Royal College is short of funds owing to lack of examination fees received from students, but if the new Bill passes there will be adequate funds for the latter. If the standard of the preliminary examination is raised you will still further decrease the number of students, and if you wish to see a better quality of men entering the profession we shall also have to contribute towards the training of them by rendering financial assistance to the Colleges. Taking into consideration the inroads made into veterinary practice by motor traction, there is very little encouragement to students to enter the profession.

Mr. SUMNER then narrated his experience of women students and made some interesting remarks.

Mr. JOHNSON (Brighton) said: The Essayist has so completely covered all the important data in connection with the matter under discussion that I have nothing to add and no questions to ask. Before leaving to catch my train, I should like to say that the hour spent in this room hearing Mr. Sumner's remarks completely justifies the step which the members of the veterinary

profession in Sheffield and district have taken in forming this new Association. With regard to the doings of the College Council we have received some valuable information, and there are numerous interesting points upon which we can go away and reflect. What I should like to say about the depletion of the funds of the College is this—If we can promote unity, and if we can co-operate as we ought through our various societies, I am convinced myself that the members of the profession will rally and will only be too ready to contribute something, whether it be a guinea or less. I feel sure the members of the profession will not allow the Council to see its old traditions and institutions broken up through the want of assistance. I gather from the Essayist's remarks that he would like an expression of opinion as to the advisability of raising the standard of the preliminary examination. Whilst not desiring to put any strain upon parents or young people desirous of entering the profession, I am strongly in favour of the Council keeping the standard of our preliminary examination on a level with that of the medical profession. Without saying any unpleasant things about those worthy men who came into the profession under the 1881 Act, or those older members of the profession who are of the old-fashioned schools where there was only one examination, and so on, our desire should always be to give our *confrères* a "leg up," rather than a "push down," and I certainly think the only way to do it, is to keep alongside the sister profession with the preliminary examination by which our profession is entered. We are encouraged to believe that there will be very important work in connection with Public Health which veterinary surgeons will have to do. Incidentally this will probably have to be done with motors, owing to the wide area to be covered, instead of working in a confined area with horses. In order to do this work I do not think the standard of education should be lowered. It seems to me that we should support the Council in keeping the standard up. On the subject of our co-operation with the medical profession, and particularly with Medical Officers of Health, I think we should make it known by tactful means that we should like a little more appreciation than we get. I do not wish to go into details, but I would like us to get a little more consideration as regards our professional status. What I mean is this—I think the world would appreciate us more if, without being too blatant or anything of that sort, we could in some quiet and gentle way express our desire for further recognition.

Mr. T. C. FLETCHER said: I should like to thank Mr. Sumner for his very interesting paper, but I must say that I cannot agree with Mr. Brown in the slightest. I think the whole world is progressing in educational matters, and I think the veterinary profession should do the same. The school boy of to-day is far better educated than formerly, and if the school boy of to-day is to be a veterinary surgeon, he will both expect and be able to pass a higher preliminary examination. I quite agree with Mr. Sumner in his expression of opinion that as the Medical Council are raising the standard of education, the veterinary profession should do the same. I hope Mr. Sumner will go away from Sheffield confident in his own mind that we appreciate his kindness in giving his important paper. If it is any honour to him to know—this is the first topic introduced to the new North Midland Veterinary Association for discussion. I have great pleasure in proposing a very hearty vote of thanks to Mr. Sumner for his paper.

Mr. ABSON, in seconding the resolution, said the members were greatly indebted to Mr. Sumner for giving his very lucid paper. He has covered a lot of ground, and I think we were all thoroughly interested in the matter he has brought forward. We are most grateful to him for coming.

The resolution was carried with acclamation.

Mr. SUMNER, in reply, said: I have no apologies to make for coming. I appreciate the honour of the invitation which my friend Mr. Lloyd has given me. It has been a delight to me. I think you have rather missed the drift of the argument that I have tried to bring home, and that was not our present condition. At present our ordinary members are equal to the ordinary medical licensee, our standard is equal, and we can meet them in any place. Now the time has come, in my opinion, when they might have a little advantage. The standard of the examination for the entry to the medical profession is to be raised, and our equality will suffer. The medical profession will then be able to say that the standard of veterinary education is not equal to theirs, and that is a thing I do not wish the medical profession to be able to say. Consequently, I hope we shall be able to say in the future that we are absolutely on an equality with the medical licensees. I can only add that I have been glad to have been here.

After Mr. Sumner had left it was decided by the meeting that the discussion should continue.

Mr. SAMPSON said: I have been pleased to hear Mr. Sumner's remarks, and have greatly enjoyed hearing from a Member of the Council remarks on the policy of the profession. It is very seldom you find a Member of Council getting up at meetings of Societies and giving his views on the politics of the profession. Were it not for verbatim reports in *The Record* we should not know how the business of the Council is transacted, and when one has heard Mr. Sumner's account of what takes place in Council, one can appreciate the difficulties the Councilors have to meet. Whilst on this subject, I should like to speak with regard to veterinary jurisprudence. I think forensic medicine should be added to the curriculum of the College. I fail also to know how a new graduate is to become acquainted with the ethics of our profession under the present course of instruction. It would be well if young practitioners could get help from Members of Council so as to learn what they should, or should not, do in regard to professional conduct. With regard to the finances of our College, I should have liked to have asked Mr. Sumner, had he been present, what has the Council done to try and cut down expenses in connection with the examinations? Have they done all that a body of business men could in this matter? Surely when they knew that their expenses were exceeding their income they would endeavour to cut down the expenses of examinations by having all the students examined at one centre. I should like to know what are the cost of the examinations at different centres, and what would be saved if the examinations were conducted at one centre. There will be no question of finance assuming that the Bill becomes law, but what is the Council going to do with the amount of money received from the annual fee. I think the profession has a membership exceeding 3000, and before the Bill is passed it is only right that members of the profession should know what the Council intends to do with this amount of money. To me it seems a rather large amount every year to be thrown into our funds for our College to deal with. We only hope that if they get this money they will take steps to amend the law so as to deal with such cases as "Kennard—Canine Surgery," so that persons running such places cannot come along and take money out of the pockets of the men who have paid for their college education. With regard to equality with the medical profession, I am at one with Mr. Sumner that we are quite justified in raising our standard to that of the medical profession—lately every education authority has been raising its standard.

THE HON. SECRETARY (Mr. Lloyd) said: The first matter Mr. Sumner dealt with was the one-portal

system, with which, no doubt, we all agree, and then followed on with the new Fellowship diploma. I, and no doubt the profession generally, will agree that something wanted doing with the Fellowship diploma. A few years ago, before the number of students decreased, the amount saved per annum by the Council about equalled the amount received from the Fellowship examination fees, but since the number of students has been reduced the Fellowship examination fees have been swallowed in the general expenses. The matter of expense in connection with examinations mentioned by Mr. Sampson is a very important one, and I cannot say what are the expenses of taking the examiners round to all the different Colleges; I know it is an immense amount of money, and it has often been put to the Examination Committee, would it not be possible to considerably reduce these expenses by having the students examined at one centre? Students from all the Colleges would then be examined under equal conditions. It is true that at present there is not power to compel the Colleges to send their students to be examined at one centre, and the Council has so far never made any attempt to cut down their expenses by trying to get such power put into the new Bill. The only powers sought in the Bill are to deal with existing practitioners—a constantly decreasing number; limited liability companies—an insignificant number; and the extraction of £1 1s. out of the pockets of members of the profession.

Another matter which could have been inserted in the new Bill is power to deal with "Kennard—Canine Surgery," (appeal dismissed), "Marshall—Veterinary Surgeon Operator," (appeal abandoned), and such like violations of our present powers, but nothing at present is being attempted to increase our powers to deal with such cases. Although having been a Member of Council for nearly four years—I am, I may say, a Member for the last time, as I do not intend to seek re-election—I have so far been unable to find out in what way the Council intends to spend the 3400 guineas received from the annual fee provided in the Bill. Matters which have been mentioned, however, are the selling of the present College buildings, and the purchase, or building, of new offices in a front street. Another matter mentioned has been the re-organisation of the library and the renovation of the museum, but what advantages these are going to be to individual members of the profession I fail to see. A word about the new diploma in Veterinary State Medicine. As mentioned by Mr. Abson, this diploma has practically been forced upon the Council, owing to the action of various Universities in instituting such diplomas. The Council, however, had the opportunity of taking the initiative in 1899, when they were approached by the University of Aberdeen in regard to post-graduate education, but in spite of the efforts of the late Professor Owen Williams, who desired to bring this about, the Council refused to take action. The result was that the University of Aberdeen did not do anything, but later the Liverpool University instituted the diploma in Veterinary Hygiene, and the Manchester University instituted the diploma in Veterinary State Medicine, but neither desire to grant their diplomas except to graduates of the Royal College of Veterinary Surgeons. They, however, did want to receive the fees for educating veterinary surgeons in order to take such diplomas. Had the Council instituted such a diploma and allowed the Universities to do the teaching, the Council would have been able to conduct the examination and to receive the examination fees. In their present attempt to institute a new diploma in Veterinary State Medicine, I think the Council are still making a serious mistake, as they are insisting upon intending candidates taking a six months' course of instruction at an affiliated school in order to

bolster up the veterinary schools, thereby shutting out any candidate who is now holding a public health appointment, as such candidates would have to give up their present appointments in order to be able to attend a College. It is still, however, open for any University to institute a diploma in Veterinary State Medicine so long as they do not interfere with the one-portal system, and should such courses of instruction be made easier than that of the Royal College, it is almost certain that intending candidates will go for the University examinations and so cheat the Royal College of the examination fees, at the same time having a diploma which, in the eyes of the public, will be equal to that granted by the Royal College.

Regarding the appointment of Dr. Leighton as Medical Veterinary Inspector to the Local Government Board (Scotland), when the matter was first brought forward by the Association of Veterinary Officers of Health it was never intended that a medical man should receive the appointment, and had not Dr. Leighton been the Professor of Pathology and Meat Inspection at the Edinburgh Veterinary College, there is no doubt that he would not have received the appointment. It is consequently up to the veterinary colleges to see that only veterinary surgeons are appointed as Professors at such Colleges.

Mr. FLETCHER (Sheffield) said: I had not finished my remarks when previously speaking. Members of the Council ask for votes at a particular time of the year through some little paragraph in *The Record* or some other periodical, and then having got the appointment of Member of the Council, we never hear from them of the workings of the Council. I only wished to thank Mr. Sumner for his outspoken reference to this work. It is good for us to know the difficulties that attend the deliberations of the Council, and it is good for us to hear that they are doing something for us, and something to warrant us giving them our votes. I am very sorry to hear Mr. Lloyd is not seeking re-election.

Replying to a question from the President, the Hon. Secretary stated that the expenditure of the Council under the new Bill would be subject to the approval of the Privy Council. The President thought the Council were standing in their own light by not clearly indicating to the profession what they desire to do with the money.

Mr. ABSON (Sheffield) asked leave, as a Member of Council, to reply to Mr. Sampson's remarks.

So far as regards reducing the expenses of the examinations as they now exist, I do not think it is possible to reduce them. The only way of reducing the expenses is to have the examinations at one centre, and I have suggested that the examinations ought to be held at York as a convenient centre. The schools, however, will not send their students to one centre, and we have no power to compel them to do so.

Regarding the annual fee received under the new Bill when it becomes an Act, the Council will have no difficulty in spending the money. We cannot do anything at present for shortage of funds. There are hosts of ways in which the money can be spent to the advantage of members of the profession generally.

In reply to the Hon. Secretary regarding the diploma of Veterinary State Medicine—it is true we might have had this diploma some time ago, but we have maintained that the teaching of the veterinary surgeon of to-day is of such a character that he should be able to undertake any post, public or otherwise, which is offered to him. It is true that we might have instituted this course three or four years ago, but it is easy to be wise after the event. I am in favour of upholding the preliminary examination, and making it equal to the preliminary examination of the medical student.

The meeting then proceeded to discuss the ordinary business which had been postponed in order to take Mr. Sumner's paper.

The HON. SECRETARY reported that he had received promises of papers to be read in 1914 by Mr. Brown, of Worksop, and Mr. Noël Pillers, of Liverpool, and hoped to be favoured with promises from other gentlemen.

New Members.—Mr. J. A. HODGMAN, Barnsley, was nominated by Mr. Smith and Mr. Fletcher.

Mr. H. W. DAWES, JUN., Sheffield, by Mr. Laycock and Mr. Abson.

Mr. G. HOWE, Buxton, by the President and Mr. Sampson.

Mr. W. C. WILKINSON, of Mansfield, was then elected a member of the Association.

ELECTION OF OFFICERS.

On the proposition of Mr. Brown (Worksop), seconded by Mr. Sampson (Sheffield), the officers for the year 1913 were re-elected, it being felt by the members present that it was undesirable, seeing that the officers had only held office for six months, to make any change.

SPECIMENS.

Mr. G. GREEN (Rotherham) brought forward a Cyclopean monstrosity, namely, the head of a hackney foal. The mare had carried the foal, which was born dead, practically the full period, but it was known to be alive the day before its birth, as the fetal movements on that day were noticed to be very vigorous.

FRONT VIEW.—A small piece of paper has been placed on the eye in order to bring it out more prominently.—J. S. L.

Parturition was easy and uneventful, except that the mare retained the membranes for some time. The body of the foal was normal in every respect. The head was as now presented to you after preservation. The upper lip and jaw had been arrested in development leaving nearly two inches of the tip of the tongue and the bottom jaw exposed; the termination of the upper lip, however, was adorned with "feelers." In the centre of the forehead was a single eye provided with two eyelids and eyelashes, one on either side of its upper border. The eyelids on the lower border were devoid of

eyelashes although rudimentary eyelashes and "feelers" appeared lower down on either side of the face. Mr. Green also stated that unfortunately he was not able to make a dissection of the optic nerves, otherwise it would have been very interesting to have noted their arrangements. The owner on being asked if he knew any reason for the monstrosity had said that he thought the mare must have been frightened by a motor car.

ULCERATION OF HEAD OF FEMUR AND ACETABULUM.

Mr. S. E. SAMPSON (Sheffield) said: The subject was a Shire filly foal, born April 12th, 1913. On April 22nd I attended the foal for pervious urachus, which was treated in the ordinary way with disinfectants and sutures. On April 29th, the foal was reported lame on the near hind leg, and I visited next day and suspected joint evil. I gave nuclein hypodermically every third day, along with a liniment over the joint. On June 1st I noticed a purulent discharge from vulva. The lameness had by this time become very acute, the limb being nearly always "carried." At other times, when the vulval discharge almost ceased, there was a good deal of pain and no movement of the limb. Various agents were tried both locally and internally, but with no improvement, the foal dying on August 12th from septic pneumonia. The post-mortem examination revealed a large abscess outside the sacro sciatic ligament, containing about a quart of semi-purulent matter. From the specimen exhibited it will be seen that nearly all the

cartilage from both the head of the femur and the acetabulum has become completely eroded.

Mr. SAMPSON concluded his remarks by asking, "What is the nature of the complaint? Is it injury of the round ligament, or is it a case of joint evil?" He also drew the attention of members present to the amount of erosion that had taken place in a given time—about 12 to 13 weeks.

The PRESIDENT remarked that Mr. Sampson's exhibit and his statement of the history of the case were of particular interest to him inasmuch as he had seen a very similar case this summer. Unfortunately he did not see the subject—a cart filly foal—during life, and obtained a meagre history only from the owner. Briefly it was about a fortnight before death the foal became lame on the near hind leg; this lameness was at the time

attributed to an injury, which it was supposed might have been caused by the overturning of a tripod for raising timber, through the dam rubbing herself against it. Subsequently a purulent discharge from the vagina was observed. The foal eventually died from septic pneumonia. A post-mortem revealed the presence of about three gallons of serous fluid in the abdominal cavity, due to peritonitis, and an abscess in the pelvic cavity containing rather more than half a pint of thick yellow pus. The latter was situated on the left side of the pelvic floor. The left half of the pelvis was removed and the bones boiled. That portion of the pelvis immediately above the acetabulum exhibited a heart shaped area, measuring $1\frac{1}{2}$ inches in each diameter, where the dense bone tissue was completely eroded. A portion of the exposed cancellated tissue about the size of a hazel nut had become segregated and could be easily moved from side to side, but could not be lifted out while the specimen was fresh.

This case corresponds very closely with that brought before us by Mr. Sampson, except that in his case the erosion of bone took place in the cavity of the acetabulum instead of immediately above it. In his (the President's) opinion both cases arose from the entrance of the pyogenic micrococci per umbilicus, constituting an interesting and somewhat unusual variation of the well known navel or joint evil.

On the proposition of Mr. Fletcher (Sheffield), seconded by Mr. Collinson (Anston), it was resolved that the specimen exhibited by Mr. Green be photographed, and that copies of the photograph be sent to the veterinary press.

On the proposition of the President, seconded by Mr. Brown (Worksop), a hearty vote of thanks was given to the gentlemen who had brought forward specimens.

The Hon. Secretary then proposed, and Mr. Fletcher seconded, a hearty vote of thanks to the President for conducting the meeting.

REPORT UPON THE PUBLIC HEALTH IN THE CITY OF DUBLIN, FOR THE YEAR 1912.—By SIR C. A. CAMERON.

In this report the Veterinary Surgeon does not make a separate report, but his name follows that of the Assistant Medical Officer of Health in the list of officials, and his work appears in the sections on the Dairies and Cowsheds Order, and on the Inspection of Meat Food, etc. Sir Charles Cameron recognised and generously acknowledged years ago the part which the veterinarian should take in Public Health work.

The outbreak of foot-and-mouth disease occupied the Veterinary Inspector's time so fully that he was unable to give as much attention to the udders of the dairy cows as he usually gives them. It will be seen from above figures that there are diseased conditions of the udder other than tuberculosis. Tuberculosis of the udder is by no means the only diseased condition that demands interdiction of the milk, for instance, a common pathological condition of the cow's udder is inflammation, technically called mastitis. Milk from such an udder, if used for human consumption, would be highly dangerous. Prof. Holst, of Christiana, found that milk from an inflamed mammary gland caused acute catarrh of the stomach and bowels in four adults and four children who resided in three different houses. They had all partaken of milk, which came from the same dairyman, on whose premises was a cow affected with mastitis, and the owner admitted mixing the milk from this cow with the milk of other cows. The identical organisms causing the mastitis were isolated in each case, proving the illness of humans originated in the bovine and was transmitted through the medium of the milk.

[This statement does not satisfy Koch's postulates, but it carries the matter so far that the necessity for further careful observation by both medical and veterinary practitioners is clearly indicated].

INSPECTION OF MEAT, FOOD, ETC.

The inspection of food is conducted by the able veterinary surgeon of the Corporation, Mr. Andrew Watson, by four meat inspectors and myself.

R.S.P.C.A. Prosecution—Dismissed.

At Folkestone on Tuesday, 11th inst., Robt. Chittenden was summoned for working a horse in an unfit state, and Fredk. Brown (Bridges and Co.) was summoned for causing the horse to be so worked. Defendants pleaded not guilty.

Mr. G. W. Haines prosecuted on behalf of the R.S.P.C.A., and Mr. Rutley Mowll represented both defendants.

Inspector Bennett, of the R.S.P.C.A., said that on the 28th October he was in Foord Road, where he saw the defendant Chittenden driving at a trot a brown gelding attached to a four-wheeled van containing parcels. Witness noticed that the animal was going very lame on the off fore limb. He stopped defendant, and pointed out the lameness. He replied, "It's all right at a walk." Witness examined the animal and considered that the lameness was due to side-bone and a badly contracted foot. The animal flinched distinctly every time he touched it. The foot was hot. The animal, in witness's opinion, was totally unfit for work. Defendant said, "The horse has been like it for about a week. It was lame on the other leg before this, and that is why it is shod with pads. I know it has a side-bone. Mr. Brown knows it is shod with pads, because of its lameness. He is responsible for the horses." On the 3rd November, witness saw Mr. Brown, who said: "I haven't any explanation to make. We know it's lame, and have had it shod with pads to ease the concussion. I know what is the matter with it; it has got a corn. I haven't seen it since I've been back, but I didn't consider it unfit for work."

Cross-examined by Mr. Mowll: Witness had not previously noticed the horse to be lame. When the horse was taken out of the cart it became restive and kicked about. Witness had not known a lame horse to kick about before.

Mr. Mowll: This was the first.

P.S. Burniston, who was in company with Inspector Bennett, said the horse was going very lame. Witness noticed the horse before Inspector Bennett spoke.

P.C. Pritchard, who was in company of Inspector Bennett and Sergt. Burniston, said the horse was lame, and was in pain.

Mr. Gillard, veterinary surgeon, said the lameness was not very pronounced, but when trotted the horse went very lame indeed on the off fore leg. Witness found side-bone on the outside of the off-fore leg, and enlargement round the pastern coronet joint. In certain horses side-bone caused lameness. The foot was contracted, and did not expand on pressure. This condition had existed for some considerable time. All the circumstances, taken together, would predispose the horse to a bruised foot. The following day witness saw the horse again. The shoe was removed and the india-rubber pads taken off. On the outside of the foot was a bruise. The sole was in a bruised condition. Some horses with a very little bruise might go very lame. The horse, without the shoe, still walked lame. When witness saw the horse it was undoubtedly suffering pain. It had no doubt for a long time had a shuffling action of the off-fore leg.

Cross-examined: The horse had been lame for some time. The bony deposit might or might not cause pain. The bony deposit interfered with the free action of the

foot. Witness thought that the existence of the bony deposit in this case gave rise to pain. The horse's foot was considerably contracted, and it was quite possible for contraction to cause pain. Witness had no hesitation in saying that, apart from the corn, the condition of the horse would render it unfit for work on the road. The corn appeared to have been in existence about a fortnight. The horse, when witness first saw it, jumped and pranced about, but the fact that the horse put its fore feet on the ground and kicked its hind legs in the air was not inconsistent with the fact of pain in the off-fore foot.

THE DEFENCE.

Mr. Mowll, in addressing the Bench, said the horse had been going about the town for 4½ years. He submitted that the lameness that was distinguishable must have been due to a corn. The horse had not been neglected, for on the 27th September some trouble was discovered on the near fore-leg, and the horse was put "in leather." Later it was fitted with rubber pads, which assisted to take off the jar as the horse's foot came to the ground. He thought that to have prosecuted the firm without any warning might be a good advertisement for the Society, but he suggested that it was scarcely fair to the defendants.

Mr. George Ibbotson, a registered shoeing smith, of Bradstone Road, said he had gained a number of prizes for shoeing in competitions open to the United Kingdom, and had also been granted the freedom of the City of London. He did the shoeing of Messrs. Bridges and Co.'s horses. On the 27th September he was shoeing this horse. He found that there had been a corn on the near fore-foot for some time. He put on leather between the hoof and the iron shoe, the object of this being to lessen the concussion. There was no reason why the horse should not have been used. On October 5th witness put rubber pads on the horse's feet. There was at that time no sign of a corn on the off-fore foot.

Cross-examined by Mr. Haines: Witness had seen the horse at work since he put on the rubbers, and it was then going perfectly sound. The corn that had developed in the off-fore foot was a new corn.

Mr. Thos. Clyde, veterinary surgeon, of Dover, said he agreed that the horse had an awkward gait. There was a sidebone in the off-fore leg, but it caused no pain. There was a very small amount of contraction. There was also a corn. Witness was prepared to take the responsibility of having the horse worked at once on the roads.

Cross-examined by Mr. Haines: The horse was a little lame when witness examined it, but it was as sound now as it had ever been during the three years witness had known it. It had an awkward gait. Eighty per cent. of certain classes of horses used for commercial purposes had this sidebone. There was no heat in the foot when witness saw it on the 29th October.

Mr. T. C. Toope, veterinary surgeon, of Dover, said that when he examined the horse on the 29th October there was a little lameness on the off-fore leg, noticeable only to the skilled eye. The horse suffered no pain from the sidebone. He found that there had been a bruise to the sensitive sole, and the lameness sprang from that. Before he left the premises the horse went, to all intents and purposes, quite soundly.

Cross-examined: The horse was suffering some pain—discomfort, like a lady wearing a tight shoe.

Mr. Fredk. Brown said that he had carried on business at Messrs. Bridges & Co.—of which he was sole proprietor—for 34 years. Defendant Chittenden had been with witness for 20 years. He had been a fairly large owner of horses during 34 years. This horse had from the first had rather an awkward gait. He had seen the animal working, and it seemed to be going all right; otherwise

it would not have been at work. He saw the horse at work after the rubber had been put on, and it was perfectly fit and sound. There was nothing to detect with the exception of the awkward gait. He saw the horse on the Tuesday in question, and it was then all right.

Cross-examined: On the day in question the horse started out at 7.30 and returned from 9.30 to 10. It was then quite sound. He knew that the horse had been stopped. The very fact of the crowd of people who appeared to see the show was sufficient for that. It was a good advertisement for the Society.

The case was dismissed. The costs were remitted to the Society.

Cruelty Case at Cheriton.

At Elham County Bench, held at Seabrook, Fredk. Tong, of Faversham, was summoned for cruelty to a horse by working it in an unfit state.—Mr. H. Myers defended.

P.C. Enfield said on October 7th he saw a bay mare attached to a four-wheeled van in Cheriton. It was trotting, and witness noticed it was very lame. He whistled to defendant to stop, but was apparently not heard. Witness subsequently saw the animal in High Street, examined it, and found it in pain and lame on the near fore foot. Witness told defendant to take the horse out, which was done.

P.C. Kenward said he saw the animal at Miss Nicholls' stables at Cheriton. It had ringbone and went lame when walking.

Sydney Bennett, Inspector of the R.S.P.C.A., stated that the horse went lame when walked, and very lame indeed when trotted. There was ringbone in the four pasterns, the near fore leg being particularly bad. There was also a sandcrack. Defendant admitted that he knew the horse had ringbone, and that it went lame when trotting, but said he never trotted it.

In reply to Mr. Myers, witness said he had not seen the van, but would say it was cruelty if the horse was driven in a van. Witness did not tell defendant that he could walk the animal home to Faversham.

Mr. F. C. Gillard, veterinary surgeon, stated that the horse walked perfectly lame, and in trotting was worse. It was an aged mare in poor condition. There was ringbone in all four pasterns in various degrees, the worse being that in the near fore leg, while there was a sandcrack on the near fore foot. There was no bleeding from the sandcrack. The mare was intensely lame, and quite unfit for any kind of work.

In reply to Mr. Myers, witness said it was cruelty to the animal even if it was only put to a walking pace, though an inexperienced man might then not notice any lameness.

Defendant went into the box, and said he was a fruiterer, of Dargate, near Faversham. He had no great experience of horses. He had no warranty with the one in question, but when he bought it for £12 he knew it had ringbone. He had never noticed any lameness, but he always walked the animal, though it was trotting when the constable saw it. He had a contract with the Council of Faversham, and the mare was working for that Corporation at the present time.

Herbert Foreman, in the employ of the defendant, said the horse had shown no signs of lameness during the four years he had known it.

Mr. H. B. Eve, veterinary surgeon, said defendant brought the horse to him on October 7th. The mare was in a fair condition, but to him, as an expert, she seemed slightly lame on the road. The ringbone had been present about five years. The horse had flat feet, and he assumed there were corns. Witness attributed the lameness primarily to what was known as a "false

quarter," which had been stated to be a sandcrack. The ringbone, and, possibly, corns, were merely contributory.

Mr. Myers said he acknowledged that the R.S.P.C.A. was doing a grand work, but one could not help thinking that some of the officials were not beyond criticism.

The Chairman said the Bench were of the opinion that the case was one of negligence, but taking into consideration that defendant took the horse out of the van when his attention was drawn to its lameness, they had decided that he should be merely ordered to pay the costs (£1 15s. 6d.)—*The Folkestone and Cheriton Herald*.

"Overstocking" Appeal—Justices to Convict.

In the High Court of Justice, King's Bench Division, on Wednesday, 19th inst., before Mr. Justice Darling, Mr. Justice Rowlatt, and Mr. Justice Atkin. *Waters v. Braithwaite*—a case stated by Banbury Justices.

Mr. Stewart Bevan appeared for the appellant; the respondent was not represented.

An information was preferred against the respondent under Section 1 of the Protection of Animals Act, 1911, charging that he unlawfully did "cause to be cruelly ill-treated" a certain cow by allowing her to be overstocked. The respondent, Thomas Braithwaite, was a farmer and breeder, and on June 12th, 1913, he caused the cow and her calf, which was muzzled, to be walked from his farm to Banbury market, a distance of five and a half miles. The cow was a heavy milker, and was in full milk. On her arrival at the market at 11 a.m. her udder was found to be very much distended. The teats were also distended, and they were hard and hot and felt like the skin of a drum. When her legs came into contact with the distended udder, milk was forced out, and there were inflamed patches on the udder. Her back was arched, she had great difficulty in walking, and had to be constantly struck to keep her moving. She was overstocked with milk. The cow had not been milked for 19 hours, and the expert evidence was that cows in full milk should be milked every 12 hours, and that overstocking caused pain and was harmful. For the respondent it was contended before the justices that it was a well-known custom of farmers throughout the country to keep cows unmilked for a like period before offering them for sale, and that it caused no substantial pain, and that interference with the custom would be detrimental to farmers.

The justices found that the udder was overstocked and that the cow suffered pain, but that as it was an old-established custom in the district to expose cows for sale in this condition, they dismissed the summons.

By Section 1 (1) of the Protection of Animals Act, 1911:—"If any person (a) shall cruelly . . . ill-treat . . . any animal . . . or, being the owner, shall by . . . unreasonably doing or omitting to do any act . . . cause any unnecessary suffering," he shall be guilty of an offence.

Mr. Bevan said that in *Ford v. Wiley* (23 Q.B.D. 203) a case of dishorning cattle, where a similar defence was set up, and in addition the magistrates found honest belief that the operation was for the benefit of the animals, the respondent was convicted.

Mr. Justice Darling: Has the case of the docking of horses arisen?

Mr. Bevan said that it had come before the High Court, but that magistrates showed a tendency to convict in such cases. He drew attention to *Lewis v. Fermor* (18 Q.B.D., 532), in which it was held that the operation of spaying a sow, being customary, and performed for the purpose of benefiting, the owner was not

guilty of cruelly ill-treating, abusing, or torturing it within the Prevention of Cruelty to Animals Act, 1849. In the present case the only result of this treatment might be to put a few pounds into the owner's pocket.

JUDGMENT.

Mr. Justice Darling said that it was found that this treatment of cows was customary, the object being that the udder should be very much distended, so that possible purchasers might see that the cows were heavy milkers. It was not denied that this caused great pain; no one alleged that it produced any benefit to the cow, but, on the contrary, it was stated to do her harm. The only benefit there was might be that of the owner. It was said that the respondent caused the animal unnecessary pain. The case proved that the pain was unnecessary as far as the cow was concerned, and the respondent did cause unnecessary suffering by omitting to have her milked, or preventing her from being milked by muzzling the calf. If the custom of doing this did exist, it was time that it ceased, and people must find some other means of judging whether a cow was a good milker or not. That class of case had been considered in *Lewis v. Fermor* (*supra*). The headnote was: "A person who, with reasonable care and skill, performs on an animal a painful operation, which is customary, and is performed *bona fide* for the purpose of benefiting the owner by increasing the value of the animal, is not guilty of the offence of cruelly ill-treating, abusing, or torturing the animal within the meaning of 12 and 13 Vict., c. 92, section 2, even though the operation is in fact unnecessary and useless." Some parts of Mr. Justice Wills's judgment did not seem to go that length; he said at page 536:—"In my opinion the proper view is that if the person who performs the operation entertains an honest belief that what is done will benefit the animal, he is not liable to be convicted. The belief may sometimes be erroneous, but we must be careful that we do not try to teach new, though perhaps improved, views on matters within the area of fair scientific discussion by means of the criminal law." But even if the case decided what the headnote said it did, it had been considered in the later case of *Ford v. Wiley* (*supra*). Mr. Justice Hawkins said at page 225:—

"If the law were that any man, or any body of men, could in his or their own interests, or for his or their pecuniary benefit, cause torture or suffering to animals without legitimate reason, and could, when charged with cruelty, excuse himself or themselves upon the ground that he or they honestly believed the law justified them, though in fact it did not, it is difficult to see the limits to which such a principle might be pushed, and the creatures it is man's duty to protect from abuse, would oftentimes be suffering victims of gross ignorance and cupidity."

Lord Coleridge at page 216 said:—"Upon the decision in *Lewis v. Fermor* (*supra*) we are not called upon to observe. It is upon a different operation, and is open to different considerations. But if my brother Hawkins is right in the view which he has taken of the reasoning in that case, I desire to say that I concur in the observations he has made upon it, and I respectfully dissent from it." They were not bound, therefore, to follow *Lewis v. Fermor* (*supra*) if it went as far as the headnote stated. There was ample authority in *Ford v. Wiley* (*supra*), and in the statute itself to enable them to say that where unnecessary suffering is caused by some act of an owner it could not be justified on the ground of old custom and of benefit to commercial persons. The case must be remitted to the justices with a direction to convict.

Mr. Justice Rowlatt gave judgment to the same effect, and Mr. Justice Atkin concurred.

RUPTURE OF THE UTERUS AFTER THE USE OF PITUITARY EXTRACT.

Dr. Germ Espent records (*Münchener Medizinische Woch.*) this mishap in a human patient. The pituitary extract known as "Pituglandol" was given subcutaneously on account of weakness in the labour pains, the dose given being 1·1 c.c.

The labour pains did not strengthen; and an hour-and-a-half later, as parturition had not advanced the same dose was repeated. Five minutes later violent labour pains set in, and caused a rupture of the uterus.—*Münchener Tier. Woch.*

[I am not aware that this accident has followed the use of any pituitary extract in veterinary practice. That it has occurred in the human subject is a fact worthy of remembrance—for the drug has yet been comparatively so little used upon animals that no one is entitled to call it free from danger.—*Transl.*]

W. R. C.

New Process of Producing Salt.

On the invitation of the International Salt Co., Ltd., 158, Bishopsgate, London, E.C., a representative of the *Meat Trades' Journal* paid a special visit to Belfast and the Carrickfergus works of the company on Saturday last to witness a demonstration of the "Tee" salt process.

Since mankind turned from a wandering to a settled life the obtaining of salt has been the most important of industries. In recent times inland African negro tribes have been known to prize salt above gold. Mungo Park related that some negroes had a way of referring to an extremely wealthy man as one who "seasons all his food with salt," the most extravagant form of luxury they could conceive. The rarity and dearth of salt in ancient times were due to difficulties of manufacture. With the progress of science and civilisation, the manufacture of salt has grown in importance. At Hayling Island, near Portsmouth, and at a later period at Salterns, on the western shore of Langston Harbour the manufacture of salt from sea water was carried on long before the Conquest; but the brine pits of Cheshire, Worcester, and Durham are worked so well and economically that sea salt making has long been an unprofitable occupation in this country. In the early seventies Dr. Mond embarked his little capital in acquiring the English rights in the Belgian Solvay ammonia soda process. He was joined by his friend, Mr. J. T. Brunner, and the two partners erected their works over the Cheshire salt deposits. After a trying and anxious time during the first year, when it is said everything that could explode exploded, and everything that could break broke, the process was improved, and success followed. There came later the electrical method of splitting common salt immediately into sodium and chlorine, adopted by Hargreaves and Bird, at Middlewich, and which has proved a commercial success.

Although the old method of evaporating the brine is the simplest process, it is by far the most expensive method of production; consequently an invention that successfully takes the rock salt direct from the mine, eliminates all the impurities, and delivers into the warehouse an anhydrous salt ready for immediate sale at a fraction of the cost of the ordinary process—performing all this in an hour and a half, as against two to three weeks for the finer grades by the brine process—is an invention that may fitly be described as "revolutionary."

The process invented by Mr. Harry Tee, and perfected by the International Salt Co., Ltd., is another example of the effect of modern science when applied to ancient methods.

The "Tee" process refines by fire. Rock salt fuses at a temperature of about 1750° Fahr. Its impurities have a far higher fusion point. This difference in melting temperatures renders it therefore theoretically possible to separate pure salt from the clay, iron, etc., with which it is associated. Many attempts have been made in this direction, but without success. From experiments made in the laboratory, it occurred to the inventor that agitation might have a beneficial effect by releasing the impurities held in suspension in the molten salt. This was effected by blowing air through the molten salt. A great improvement in the colour was at once noticed, but there was still an insufficient separation of the heavier impurities. After further experiment the salt was maintained in a molten but quiescent condition after "blowing" with a view to permitting the foreign matter to settle out by virtue of its greater density. It was then found, when the solidified mass was turned out of its crucible, that the whole of the earthy impurities had been deposited at the bottom of the vessel in a distinct stratum, the separation showing a clean cut line, the mass above it consisting of pure white salt of the highest quality.

It remained to perfect the plant for dealing with large quantities, and to procure a greatly increased yield of salt per ton of coal. Both these desiderata have been successfully overcome, and after about two years of costly experimental work the process has been perfected, and is being operated at the works upon an industrial scale.

Melted in large gas or oil fired furnaces, the liquefied salt, after passing through a series of settling chambers, emerges into large cauldrons, where, by a simple mechanical process, it is rapidly crystallised, and delivered to the screens in a warm state, any grade and quality of absolutely pure, dry salt being produced at will in a few minutes. This new salt has been aptly registered under the name of "Alsalt," and the Company make special points of the sterilisation and purity of the salt, and of its containing no added ingredients whatever. The saving in fuel may be characterised as amazing. Whereas by the old method a ton of coal produced about two tons of salt, the new "Tee" process, with the same amount of fuel, produces about twelve tons of finished purified salt. The situation on the shores of Belfast Lough is most advantageous and accessible. The reserve of rock salt is unlimited.—*Meat Trades' Journal*.

The Treatment of Horses in the Recent Army Manœuvres.

We wish to call the attention of the authorities at the War Office to the condition of the horses which came through the recent army manœuvres. Some of these horses were seen by the Editor of *The Animals' Guardian* in the Horse Market at Brussels and on the wharves at Antwerp. *The Daily Telegraph* in October contained numerous advertisements of sales of horses fresh from the manœuvres, which might have been retained in the service, or certainly disposed of in the country. They bore most evident signs of very hard usage, and had been bought by dealers for the continental market. These were mainly horses supplied by contractors, but from information which has reached us from Woolwich, the condition of the army horses proper, which had been returned there at the end of the operations, was such as to arouse indignation and astonishment among many army men. They have been

described to us as "wrecks" and "clothes-horses." The British Army costs the British public many millions of money in the course of the year. Who are the transport officers responsible for the proper feeding and care of these animals on the line of march and in the operations which were carried on during the early autumn? We hear a great deal about the increasing efficiency of the army. Well, we accept it; but what about the horses? Who is responsible for them? We should not be at all surprised if some pretty significant questions were asked when Parliament reassembles concerning this serious state of affairs.—*The Animals' Guardian*.

Ireland and Cattle Disease.

The Irish Department of Agriculture has been informed by the Board of Agriculture and Fisheries that 51 Irish cattle, which had recently been brought on to this farm of Mr. S. H. Weston, at Westham, East Sussex, on which there has been an outbreak of foot-and-mouth disease, have been examined, and that no evidence of the disease has been found among them.

The Milk Question again.

"You are charged with selling adulterated milk," said the magistrate.

"So I understand, your worship. I plead not guilty."

"But the testimony shows that your milk is 25 per cent. water."

"Then it must be high-grade milk. If your worship will look up the word milk in your dictionary you will find that it consists of from 80 to 90 per cent. of water. I'd ought to have sold it as cream."

Royal Veterinary College Annual Dinner.

The annual dinner took place at "The Trocadero," on Friday evening, 14th inst., Principal Sir John McFadyen in the chair, supported by Professors Macqueen, Shave, and Wooldridge, with visitors: Messrs. H. A. MacCormack (Central V. Society), and G. J. Harvey, late G.V.S., Cyprus. The company numbered just under 90. After the dinner—which was judiciously selected and, as usual there, well done—Sir John gave "The King," which was loyally honoured, and with "permission to smoke" the musical programme was commenced. Songs were given by Messrs. R. M. Bamford, T. H. Lockley Turner, A. G. Lalor, and T. J. Dixon, backed by Messrs. Harry Hall and George Blackmore. Musically, Mr. F. H. Stainton's violin solos were an easy first, and were vigorously encored, as, indeed, were the other contributions. Mr. R. H. Lucas proposed "The College," and took the opportunity of airing some of the students' grievances—none of them serious, some of them fancied rather than real. Professor Wooldridge, in replying, referred to one of them—a lack of enthusiasm on the athletic side—and pointed out that while some of the students might feel that they could ill spare the time, athletics, judiciously used, are a healthy and necessary tonic, and often sent the man back to his studies with a clearer brain and a freshened grip of his work. Prof. Shave proposed "The Chairman" in the only suitable terms, and Sir John replied briefly. "The Visitors" was given by Mr. W. J. O'Connell. Mr. G. J. Harvey, in reply, complimented the students on the style and tone of that night's dinner as compared with his student days; and Mr. MacCormack, who also replied, recalled the time when their annual dinner was held at "The Horseshoe." He also advised the students, as soon as they obtained their diploma, to join the National Society, preferably through a local Society—the Central he would say—and pointed out the undeniable advantage of the member-

ship, both to themselves and to the profession as a whole.

Prof. Macqueen gave a well-deserved toast not on the programme—the Dinner Committee, with the Hon. Sec., Mr. E. E. Jelbart. He, too, complimented the students on the whole tone of the function and compared it with earlier experiences, when "the atmosphere had been too thick for him, and he had given up attending them for some years." The evening was a success, and the appearance of the contingent present gave promise of maintaining the prestige of our oldest school for another generation of veterinary surgeons.

Dinner to Mr. Robertson.

The esteem in which Mr. William Robertson, M.R.C.V.S., is held by citizens and farmers alike was evidenced on Saturday evening, October 25th, when he was entertained at a complimentary dinner at Steinmann's Hotel, Grahamstown, by a gathering which Dr. Drury described as consisting of "farmers, doctors, and oddments."

Mr. T. T. Hoole presided. The company, numbering over 60, included the Mayor, Dr. Griffiths, Dr. R. T. Harrison, Prof. Williams, Dr. Drury, Dr. Duerden, Prof. Bowles, Colonel Greener, Dr. Lea, Canon Wyche, and Prof. Schwarz.

After the loyal toasts,

Dr. Drury, in the unavoidable absence of Dr. Saunders, proposed the health of the guest of the evening. Dr. Drury said Mr. Robertson ranked very high in the class of men who worked. If one tried to sum up all one knew of Mr. Robertson, he would say he was a hog for work. He came from a place north of the Tweed where the people went in for low living and high thinking. (Laughter.) Ever since he came to Grahamstown he had been characterised by his hard working. They were sorry when he left for the north, but he (Dr. Drury) did not know of the return of any prodigal son which had been so welcome. (Hear, hear, and laughter.) He was a colleague and a friend; a man of wide reading. No one had ever appealed to him in vain for help for his dog or any other animal. Speaking as a medical man, he was jolly glad he had returned to Grahamstown. (Cheers.)

Mr. Charles Gardner, of Alexandria, supported the toast, and said he voiced the feelings of all the farmers when he said he offered him a very cordial welcome on his return to this part of South Africa. He was their good and true friend. As a sportsman he was not to be beaten, and one always welcomed a visit from him to a farm. (Applause.)

Mr. Robertson, who was cheered on rising to reply, stated that within the short space of thirteen months he had experienced speeding and parting, and welcoming the coming guest. It had been said by a man who had travelled very widely through the Union of South Africa that there were only two places worth living in—one was Capetown, and the other Grahamstown. He (Mr. Robertson) had had the pleasure of living in both, and he certainly preferred the latter. (Applause.) He had been connected with Grahamstown, Upper and Lower Albany, Alexandria, and Bedford for nearly sixteen years, which was no inconsiderable part of the working span of a man's life. During that time he had come mostly in contact with the farming community. Sixteen years ago he was mighty green in regard to the stock diseases of the district, but during that period he had received very much assistance from the farmers, and many valuable hints in his work of investigation of animal diseases in the Eastern province. He had, moreover, always received the utmost kindness and courtesy. He did not think he had a single man who had a spite against him in his professional capacity. When he went

to the Transvaal he felt he was called upon to do so but he soon learnt the difference between the two places. It was only when one found himself removed from civilization—(oh, oh)—yes, he was seven miles out of Pretoria, beyond the sanitary dumping heaps—and found farming conditions different and no personal comfort that he realised the advantages of Albany. There was no part of the country which had made such vast strides in the matter of stock and personal comfort as the district he had mentioned. Fifteen years ago there were no houses to compare with those now built, and so it was with stock. They had probably the finest cattle to be found in the Union. He had inquired in England where were the Ayrshires and big cattle, and he was told that the men in South Africa and the Argentine were buying them, and that South Africa had better cattle than were being bred in England. Here was a lovely country, an equable climate, a splendid rainfall, nothing to trek for, and one of the finest labour supplies through the whole of the Union. He thanked those present very heartily for their welcome to him and trusted the kindly feeling existing between the men in the district and himself would continue. (Cheers).

Songs, recitations and anecdotes brought an extremely agreeable evening to a close.—*Grocott's Penny Mail.*

THE LATE WILLIAM HUNTING.

Mr. Trevor Spencer writes:—"I should like to tell you with what sorrow I received the sad news of the death of the revered Editor, and how conscious I am of the blank which his loss means to every member of the profession the world over. In my opinion he was one of the greatest all round men who has ever adorned our ranks, and it is difficult to believe that his place will ever be really filled. This humble word of appreciation is somewhat belated, but I have had one hand disabled, and that has interfered with my correspondence."

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons (Limited), official sale agents in England and Wales for Parliamentary papers and Stationery Office publications, have published the following, the price including postage: Foot-and-Mouth Disease in Ireland: Report for 1912, 1s. 10d.; Irish Milk Commission Final Report, 8d.; Milk and Cream (No. 2) Circular, 1½d.

CORRESPONDENCE.

PATENT MEDICINES FOR ANIMALS.

Dear Sir,

Prof. Hobday and Dr. Lander are to be heartily congratulated upon the course they are taking with regard to patent medicines for animals. It is quite time that something was done to enlighten the public as to the very harmful effects some of the terrible concoctions have.

One very widely advertised specific, to my knowledge, has caused the death of several horses and a number of cows, besides being the means of an unfortunate cowman losing an eye through a drop falling into it while drenching a beast. It is so irritating that whenever given to horses it has removed nearly all the epithelium from the mouth—to say nothing of the pharynx and stomach, and must have caused the most excruciating pain. When injected per vaginam for the removal of the afterbirth (as recommended on the bottle) it has caused severe sloughing of the mucous membrane, straining, and sometimes death.

At my suggestion the R.S.P.C.A. have taken up the matter and warned the manufacturers of its irritating character.

One can hardly comprehend—unless one visits the stands at our large shows—how it is such mixtures are bought at all, but the fact remains that large quantities are so purchased by a confiding public.

If Dr. Lander and Prof. Hobday can lessen this evil they will have earned the gratitude not only of veterinary surgeons but of every horse lover.—Yours faithfully,

G. P. MALE.

Reading, Nov. 18.

REBATE ON PETROL.

Sir,

I am obliged to Mr. B. P. J. Mahony for having so promptly taken up the question of a rebate on petrol. When a suggestion which concerns our profession is made by an individual, it is too often passed over and there is no more heard of it. How differently do members of the medical profession act.

Mr. Mahony's spirited offer is to be admired, and I would gladly take on myself to do as he desires, were it not that I consider concerted action by our Societies would prove more effectual—especially as I am not sure of its being a question for the Law Courts in the sense that Mr. Allen's case was. The latter would depend upon whether the rebate to the sister profession was inserted in an Act of Parliament to "the medical profession," or was merely an after concession granted by a Minister of the Crown.

A consultation could be more conveniently held at a general meeting, and as one will be held by the V.M.A. of Ireland during this month, let us hope that members will make it their special business to attend in large numbers and set the petrol ball rolling.—Yours truly,

JOHN HOLLAND.

Athy. Nov. 1st.

THE UPKEEP OF MOTOR CARS.

Sir,

I read Mr. Woods' letter on "the upkeep of motor cars" with interest. If the cost of repairs to the car is roughly £1 per week, is 20% depreciation sufficient to allow? What does the item "car, chauffeur, and depreciation at 20% per annum" mean? Why put the chauffeur in along with the depreciation?—Yours truly,

G. MAYALL.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1325.

NOVEMBER 29, 1913.

VOL. XXVI.

THE INTERNATIONAL VETERINARY CONGRESS.

To-day we print a subscription list from Mr. Garnett which shows that this fund is making rather better progress than when we alluded to it a few weeks ago. At that time over £300 was needed to reach the minimum, then fixed at £3500. To-day the shortage only amounts to about £200. But as the Congress approaches it is becoming clear that an unusually large number of foreign visitors may be expected to attend it, and therefore it has been found necessary to raise the figure of the minimum sum required. It is now estimated that £4000 will be wanted to make a successful Congress, and Sir John M'Fadyean, in the personal appeal he has circulated within the last few days, states that amount as necessary. At present, then, £700 is still required for success.

If most of our members had already subscribed to the fund, it might be difficult to raise another £700. But so many have not yet subscribed at all that the task ought to be easy. If half the men who have not subscribed were to give half-a-guinea each, the whole sum would be raised at once. This large proportion of non-subscribers amongst us is alluded to by Sir John M'Fadyean in his circular letter. He suggests that many who could afford to subscribe "have not done so because they have not realised to what an extent the honour of the profession is pledged to see that the Congress in London shall be no less successful than any of those previously held." This is a crucial point—most of us do not yet recognise how much is at stake. If the Congress should fail for lack of funds, the whole discredit of the failure will fall upon English veterinary surgeons; a little thought will convince everyone of this. And the sum now required is comparatively small.

THE UPKEEP OF MOTOR CARS.

Recently Mr. W. Woods published the second year's upkeep cost of his motor car. Thanks are due to him, and we wish that other veterinary motorists would follow his example. An increasing number of practitioners now use motor cars—or think of doing so, many of the latter know little of their working cost, and to these such reports are valuable, so also would be similar reports of the smaller cars, cycle cars, or even of the single motor cycle, which is very useful in some practices. One year's report is enlightening, reports extending over a series of years, such as that furnished by Mr. Woods, are more so.

IS ANTI-TETANIC SERUM CLINICALLY EFFICACIOUS AS A PREVENTIVE?

On page 264 of *The Veterinary Record* for October 25th, 1913, Mr. W. G. Burndred, in his paper before the Lancashire Veterinary Medical Association, described an accidental penetration of the abdominal wall of a horse.

"Case No. 5.—By morning, urgent symptoms were relieved. Tetanin was injected as a preventive. The wound kept healthy; and there was no discharge. Tetanus developed on the ninth day, and in spite of further injections of tetanin, the animal grew rapidly worse and died on the eleventh day."

In the discussion which ensued,

"Mr. Noël Pillers referred to the case in which tetanin was injected as a preventive, and he presumed that anti-tetanic serum was meant. If so, he failed to see why tetanus should supervene, as the serum was reliable. Was the serum from a good firm, and was the dose sufficient?"

In his reply, Mr. Burndred said:

"In Case No. 5 he did use anti-tetanic serum which was obtained from the Pasteur Institute."

In the report of the annual meeting of the North Wales Veterinary Society in *The Veterinary Record* for November 8th, 1913, page 309, Mr. L. W. Wynn Lloyd, in describing the progress of an operation for umbilical hernia in a horse, says:

"As we had attended a case of tetanus on this farm, we injected a dose of anti-tetanic serum on September 6th as a precaution. On the 23rd we went to remove the clam, and were surprised to find that tetanus had set in. The clam was removed, and serum injected daily for eleven days. He was taken out for exercise on October 14th, and has since maintained good progress."

Thus, within a short time, we have two records of the failure of anti-tetanic serum to prevent lock-jaw. The question naturally arises in one's mind as to how many cases of failure are met with in practice, and not recorded. Following upon this, many would like to know the reasons why the disease supervened. The serum, the method of use, the patient, and the surroundings have to be investigated.

Bacteriology tells us that anti-tetanic serum is in reality a dose of bodies which will neutralise the toxin of the bacillus.

In the above cases, was the proper dose used? Was it carefully made, and was it fresh and uncontaminated? If bacteriology is correct, and the material was used as directed and was fresh, are the manufacturers liable for the animals?

Possible chances of error creep in with the method of injection, especially if some of the

injection escapes; the patient one would imagine to be a constant factor, but it is conceivable that a surrounding teeming with tetanus bacilli might allow the wound to become so affected as to generate toxin enough to neutralise the anti-toxin.

It would be interesting to hear what Messrs. Burndred and Wynn Lloyd have to say in explanation of their cases. Unless there is some satisfactory explanation, one must not think that a dose of serum will do away with insurance in standing-operation castration cases.

"PRE-HISTORIC."

CANKER.

By W. R. DAVIS, M.R.C.V.S., Enfield.

It has been said by Chabert that canker is the opprobrium of veterinary medicine. If he had made that statement with regard to mammitis I would have agreed with him. As to canker, I have found it to be a disease very amenable to treatment. Every case that I have undertaken to treat during the last ten years has recovered, and has got better quickly.

I have adopted a method of my own after having had failures when applying some of the lauded remedies. I have tried the hot iron, which is barbarous; caustics, which are cruel; bits of tightly rolled tow, which are fantastic; arsenic internally, which it is said is of service in the other branch.

If one reflects a little it becomes apparent that in canker we have to do with a skin disease, for the part affected is the keratogenous membrane, and what is this but a slightly altered skin? The disease is a chronic catarrh of slightly altered skin. Why then should it not be treated as eczema? This is how I presented the case to myself, and I found my assumptions abundantly justified by the results obtained when putting them into practice.

There is a great difference in the gravity of the cases presented. Supposing the frog only is affected, four to six dressings should put the case right, even if all four feet are affected. When the disease has extended to the sole a longer period of treatment is, of course, necessary, say ten or twelve dressings.

Where the wall is involved the case assumes increased gravity. If the horse is not a valuable one I would not attempt treatment if the wall in all four feet was badly diseased; not that such a case cannot be cured, but that economically it is not worth undertaking.

As a rule, when the wall is affected it is that of the hind foot. If the wall of both hind feet together with the sole and frog are diseased, a cure may be looked for in three or four months.

I have a mare under treatment at present that had all four feet diseased; frogs and soles of both fore feet, frogs, soles, and wall of both hind feet. The wall of the off-hind foot was so severely affected that the disease had nearly reached the coronet on the inside, and on taking hold of the heel the wall and bar could be moved to and fro, so great was the destruction of the laminae. I admit

that she has been a long time under treatment—nine months—but then she has worked more than seven months of that time every day, and was only dressed once a fortnight, or once in three weeks. The fore feet were cured in a couple of months, and then to dress the hind feet, the mare—a very spiteful brute—had to be cast every time the dressings were applied, except the last time, when she stood perfectly. I am convinced that only one more dressing is required to effect a cure in this case, as the only trace of disease now is a little hole at the heel on the inside of each hind foot.

This is the worst case that I have ever seen. The animal was very lame, and was unable from this cause to work for the first two months. I believe that a horse with canker is best at work if there is no lameness.

I do not propose to publish my method of treatment for the benefit of grooms, farriers, quacks, and clever farmers, but I am not unwilling to answer letters from members of my own profession who have difficulties in the treatment of the malady.

[We entirely endorse Mr. Davis' reticence in this matter. It is not a "scientific" attitude, but it is common prudence. Most men who touch country practice become acquainted with cases of cruelty—the cruelty of ignorance and conceit—some of them abominable, in the "doctoring of animals."]

ABSTRACTS FROM FOREIGN JOURNALS

THE CONTAGIOUS MAMMITIS OF MILCH COWS.

Fernand Espouy has published (*Le Progrès Agricole*) an article upon this subject. The disease is known in Germany and Switzerland, where it is very common, under the name of Gelbert Galt. It is caused by various microbes, and especially by the streptococcus of Nocard and Mollereau, from which the name of streptococcic mammitis has also been given to it.

The first symptom is simply a diminution in the quantity of milk. The appearance of the milk is normal, but it "turns" rapidly, and causes the coagulation of other milk with which it is mixed. Later, the udder hardens, an indurated nodule ranging from the size of a pigeon's egg to that of a baby's fist, appears about the base of the teat, and the milk secreted by the affected quarter becomes still less in quantity, and is watery and bluish. In other respects the animal's condition is not altered, the appetite and spirits are maintained.

The lesions only develop very slowly, but after a few months the induration has involved from one-third to one-half of the affected quarter. The milk has now lost its ordinary characters and is viscous, reddish brown or yellow in colour, salt in taste, and contains numerous fragments of casein in suspension.

At first the inflammation is confined to one quarter alone, but later it affects the other quarters in succession. The milk diminishes more and more, and finally disappears.

Contagion from cow to cow is not direct, and infected litter plays no great part in disseminating the disease. The great factor in contagion is the intermediance of milkers, perhaps by neglecting to wash their hands after each milking, perhaps by the common practice of rubbing the teat with previously drawn milk before milking. The milker thus transmits the disease, not only from quarter to quarter in the affected cows, but also from cow to cow. The microbe, brought to the teat by the milker's hands, penetrates the milk duct to the interior of the gland, and there multiplies and causes the disease.

This contagious mammitis only occurs sporadically upon farms where the calves suck directly from the teat, while it assumes an enzootic form upon farms where the cows are milked by hand.

The causal streptococcus may be encountered in the litter, and may at a given moment manifest virulence and provoke infection. This, however, is a rare mode of contagion. Most frequently the disease appears in a cowshed through the introduction of an infected cow, and is then transmitted from cow to cow, and from cowshed to cowshed by the milkers.

Treatment can only have good results when it is undertaken at the commencement of the disease. Intra-mammary injections are used—either a 4 per cent. solution of boric acid (Nocard), or a 1 in 1000 to 1 in 200 solution of fluoride of sodium (Moussu). These injections are repeated two or three times at intervals of five or six days, and the treatment is completed by applications of an "anti-mammitis ointment." By degrees the indurated nodule disappears, and the milk regains its normal characters.

When the lesions are old, and the induration considerable, complete recovery cannot be hoped for. The simplest treatment then is to remove the source of contagion by completely drying up the diseased gland. This may be effected by injecting either a 10 per cent. solution of boric acid, or a solution of nitrate of silver (Weber), or Schmidt's solution (equal parts of absolute alcohol and glycerine, 125 grammes each). When several quarters are affected, they are treated successively.

Prophylaxy is more important than treatment. Separation of the healthy from the diseased animals is of prime moment, and thus the early diagnosis of the disease becomes very important. Microscopical examination of the milk is the best method of effecting this. But the microscopical examination of milk demands apparatus and advanced technical knowledge, and a method more within the reach of agriculturists is desirable. Trommsdorff, Ernst, and others have supplied one. They have found that chronic mammitis is accompanied by a considerable augmentation of leucocytes in the milk, which may be demonstrated by collecting milk in graduated capillary tubes, and allowing them to stand for a few hours, or preferably centrifuging them. A deposit is thus obtained, which is clearly visible upon a black ground, and which, although slight when the cows are healthy, is very abundant in diseased animals. The graduation of the tubes

permits the amount of the deposit to be measured. This method is commonly practised in Germany, and is sufficiently precise to give useful indications, and to permit the detection and isolation of cows in the early stages of the disease.

The author mentions some prophylactic measures which will suggest themselves to all clinicians, such as separate attendants for diseased and healthy animals, disinfection of milkers' hands after each milking, removal of litter, and disinfection of cowsheds, etc. The milk from affected quarters should not be spilled upon the ground, as is often done, but should be drawn into special receptacles and sterilised by boiling. It may then be used for feeding pigs.

Lastly, in regions where contagious mammitis is enzootic and permanent, it is important to pay great attention to newly-purchased cows. Their udders and milk should be carefully examined, and they should not be placed in the general cowshed till they have first undergone a period of quarantine.—*Annales de Méd. Vét.*

W. R. C.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, AUG. 3—8, 1914.

Since you published my last list in *The Record* of May 3rd, I have received the following donations, either promised or paid, to the Organising Funds of the Congress.

I have not yet reached by some £200 the minimum which the Committee thought would be necessary to carry the Congress through with credit to the profession, and they now find that the minimum they first named must be very largely increased. With this end in view therefore, Sir John M'Fadyen has addressed an appeal this week to all those who have not yet sent a donation.

I shall be obliged to anyone calling my attention to errors in the present list. Donations to the Organising Fund should be sent direct to, yours faithfully,

FRANK W. GARNETT, Hon. Treas

Dalegarth, Windermere.

Nov. 22nd.

CENTRAL VETERINARY SOCIETY.

An ordinary general meeting was held at the Holborn Restaurant, on Thursday, November 6th. Prof. G. H. Wooldridge in the chair.

The minutes of the previous meeting were taken as read and confirmed.

CORRESPONDENCE.

The Hon. Sec. read the following letter from the Secretary of the Royal College of Veterinary Surgeons:

"Your letter conveying a resolution passed by the Central Veterinary Society with regard to the Anaesthetics Bill was laid before the Parliamentary Committee here on Thursday last. As, however, the Bill is no longer before Parliament, it was decided that the letter be allowed to lie on the table."

The Hon. Sec. announced the receipt of Memoirs of the Department of Agriculture in India. "Some cases of Surra treated in the field and in the laboratory during the autumn of 1911," by Major J. D. E. Holmes, M.A., D.Sc. I.C.V.D. The Hon. Sec. was requested to write and thank Major Holmes for sending the Memoirs.

Letters and telegrams were received from the following regretting inability to attend the annual dinner: The Right Hon. W. Runciman, M.P. Sir F. Low, K.C., M.P., Dr. Bashford, Dr. O. C. Bradley, Prof. McCall, Prof. Mettam, Messrs. J. H. Carter, J. T. Angwin, M. Tailby, S. Villar, W. L. Harrison, and C. Roberts.

Elections, Nominations, and Resignations. Vet.-Maj. W. A. PALLIN, The Royal Horse Guards, Windsor, and G. P. MALE, Esq., Reading, were unanimously elected Fellows of the Society.

Messrs. W. NORMAN THOMPSON, M.R.C.V.S., Midland Railway; B. A. McGUIRE, M.R.C.V.S., 469, Oxford St., W.; W. H. ANDERSON, M.R.C.V.S., Rochester House, Uxbridge; and M. G. BYERLEY, M.R.C.V.S., 56, South Street, Greenwich, S.E., were nominated Fellows of the Society, and will come up for election at the next meeting.

Vet.-Major E. P. BARRY, and F. O. PARSONS, Esq., tendered their resignations. The Hon. Sec. was instructed to write these gentlemen asking them to reconsider their decision.

THE LATE MR. WILLIAM HUNTING.

The PRESIDENT: We have now a very sad duty to perform, namely, to record our irreparable loss in the death of Mr. William Hunting, one of the founders, and, therefore, one of the oldest members, a past President, and one of the present members of the Council of this Society. When we heard of his decease your Secretary arranged for a floral tribute to be sent, and he and I attended the funeral as your representatives, as well as on our own personal behalf.

Mr. Hunting was so well known to all of us that each of us feels that he has lost a close personal friend. His

personality was absolutely unique. Indeed, when anybody had a few minutes conversation with him in a crowded room he always made you feel that you were in reality the one person above all others in the room that he wanted to talk to. Of whom else could such a thing be said? He was one of the most regularly attending members at our meetings, frequently introducing subjects for discussion, and always ready to join in and give us the benefit of his opinion, which was so valuable on account of his wonderful power of introspection and his unique experience. Moreover, he was never dogmatic in his opinions, and he showed the greatest tolerance and respect for the views of others who did not agree with him. No doubt it was these qualities that made him such an ideal examiner. In an examination, he made his candidates feel so much at ease that he could always get the best out of them, and it was not until afterwards, on reflection, that the examinee realised the great extent of the ground he had been taken over. His idea was not to find out what a student didn't know, but to find out what he did know. Students have indeed lost a good friend also.

Of Mr. Hunting's professional and other attainments much has been written, and I do not wish to refer to them now, beyond saying that he was an ornament to every branch of the work which he undertook. He might have amassed a large fortune if he had devoted himself to his own personal interest, but Hunting lived for his profession, and I feel sure that you will all agree with me when I express the opinion that there has never been a man in our day, or any other day, who has done more for the general welfare of the veterinary profession and its members. His name will be handed down to posterity as one of the giants of the veterinary profession, through some of the most critical periods of its existence.

In addition to his serious side, Mr. Hunting possessed the keenest sense of humour, and though this is not quite the time to refer to it, I am sure that many of us could contribute some interesting note that would be worthy of including in any "Memoirs of Hunting," if anybody would undertake to compile them.

In conclusion, gentlemen, I can only express the sadness at heart that I feel in the loss of one whose friendship I was more than proud. It is really difficult to realise that we shall not have him at our meetings any more. I now propose to you that a vote of condolence be passed, and that a letter be sent to Mr. Fred. and Miss Hunting expressing our deepest sympathies with them in their very great loss.

The resolution was passed in silence, the members standing.

THE ANNUAL DINNER.

Immediately following the meeting of the Society the annual dinner was held, to which 85 sat down. Prof. G. H. Wooldridge presiding.

Following an excellent dinner, the President proposed the usual loyal toasts, which were accorded musical honours.

Sir STEWART STOCKMAN, in proposing the toast of "The Central Veterinary Society," in the unavoidable absence of the President of the R.C.V.S., said the Society claimed to be the largest, and very nearly the oldest, Society of its kind in Great Britain; it claimed to exercise a considerable influence upon what might be called the veterinary thought of the country, and to exercise a benign influence on the destinies of the veterinary profession. It fell as a duty to him sometimes to collect sums of money from the profession for benevolent and public objects, and he had always met with a generous and courteous response from members of the Society. He had much pleasure in proposing the toast, and in associating with it the name of Professor

Wooldridge, whom he congratulated upon the position he occupied, and desired to convey to him that our members considered it a great honour that he should occupy the position of President. (Cheers.)

The toast was accorded musical honours, "For he's a jolly good fellow" being heartily sung, and three cheers being given for Prof. and Mrs. Wooldridge and family.

The PRESIDENT, in responding, said he felt it a very great honour to occupy the chair, an honour he owed entirely to the kindness of the Fellows of the Society. He thanked them for the very hearty way in which the toast had been drunk. He thought there might be a good reason for the heartiness of its reception. It reminded him of an old Scotch toast in which the members rose and drank to themselves, saying, "Here's tae us, wha's like us," and if they realised they had been drinking to themselves in that way, it might to some extent account for the heartiness of its reception. The International Veterinary Congress was to be held in London next year, and as it would occur in his year of office it made him particularly anxious for its success. As Sir Stewart Stockman had already pointed out, the Society had not been backward on previous occasions when assistance for such objects was required, and he was sure he would have their assistance and hearty support next year in making that Congress a success, though the responsibility for its success rested largely upon the whole of the veterinary profession. He was, like Mr. Alfred Lester, an optimist, and always looked on the bright side, and he was sure he would not look in vain when he asked the members of the Society to rally round him on that occasion. He was an optimist of the same order as the small boy who, when asked what an optimist was, said "He is a man with one eye who is thankful he was not bow-legged. (Laughter). He hardly thought they were serious in what they sang after drinking the toast. (Cries of "We were.") It made him feel something like the prisoner at the bar, or rather the man who was hauled up to answer for some misdemeanour, and who was acquitted, and a friend said to him when he got outside "Look here, Bill, you did do that, didn't you?" and the man replied, "I thought I did until I heard the lawyer make that speech on my behalf, and now I hardly think I did." (Laughter.) He was pleased that they did not omit a cheer for the little Wooldridges. They consisted of a nice little pug dog and a cat, but as they were members of the family, he was very pleased they were not omitted. (Laughter.) He again thanked them for the way in which they had honoured the toast, and with them hoped the Central Veterinary Society would continue to flourish and to carry on the good work it was doing for the general welfare of the veterinary profession.

Sir SYDNEY OLIVIER, K.C.M.G., who on rising to propose the toast of "The Royal College of Veterinary Surgeons," was received with loud cheers, said he felt it a great honour to be asked to propose the health of the Royal College of Veterinary Surgeons, which was the organising body of that important profession. He shared the regret which had been expressed at the absence of the President, Mr. Carter. He felt a special degree of sympathy with the toast, because he represented the Board of Agriculture, the Government Department which must most vividly recognise the importance of their profession. For a good many years, he had been as the Governor of a very large and important Colony, greatly interested in the rearing of stock and the preservation of the health of men, and through his Colonial experience he had learnt very fully to appreciate the function which their profession performed, not only in respect of the life of animals, but in respect of the life of man. Nothing had been more remarkable than the great broadening of the provinces of almost every department of medical science during recent memory. At the International Medical Congress an

important paper was read showing how the boundaries between what was considered the medical and the surgical had been broken down by great discoveries in regard to the causes of disease, and in like manner there had been a breaking down of the barrier between veterinary science and medical science. Many diseases of animals directly affected man, and they could not study the diseases of animals without studying the diseases of man. Conversely, the study of the diseases of animals afforded analogies to those which afflicted the human race—(hear, hear.) He recognised the enormous importance of the veterinary profession in advancing the health as well as the wealth of humanity. In attending to the health and welfare of animals they had an important function in maintaining the wealth of the community so long as animals were regarded as subsidiary to the wealth of mankind.

He was sorry to find that at the present time veterinary and medical science seemed to be suffering from an atmosphere of depression. There seemed to be a spirit of panic with regard to the future of their profession, and to his great concern, and that of the Board of Agriculture, the Royal College of Veterinary Surgeons was to some extent in financial difficulties, so that it had become necessary for them to promote a Bill in Parliament in order to re-enforce their position as a College by imposing a levy upon the profession to enable the College to carry on its necessary work. The Board of Agriculture were in favour of that Bill, and he only regretted that the enormous congestion of public business last session rendered it quite impossible for the President of the Board of Agriculture to say that the Government would lend its active support to it. They had to sacrifice a good many of their own Bills, and could not take up the Bill, which, nevertheless, they recognised was very necessary to those special interests which the Department had to watch over. He hoped that in an early session of Parliament they would be able to obtain that strengthening of the organisation of the Royal College of Veterinary Surgeons which the leaders of the profession had come to regard as necessary. (Hear, hear.)

There was a certain amount of despondency and hanging off from the profession, which he thought was quite mistaken. At the present time the Board of Agriculture were unable to fill appointments for Inspectors in their Department, and Professor Wooldridge had just told him that he was constantly applied to by veterinary surgeons to nominate assistants, but was unable to do so. The Department of Agriculture felt the disadvantage of that state of things so much that they had taken the step of recommending to the Treasury the doubtless very staggering proposal that they should increase the inducements offered in their Department to veterinary surgeons for entering their ranks by increasing the initial salary and allowing it to go up to a higher rate. (Cheers.) It was essential that the British Government should co-operate with the Royal College in its endeavour to place the profession on a sounder and more promising basis. The Board of Agriculture felt that need, and were endeavouring to respond to it. In recent times a Development Commission had been established whose function it was to pay attention to the needs of the community in regard to the encouragement of such sciences as veterinary surgery, and although the Development Commission had not yet actually published or authorised the plans which they proposed, they had shown a desire to frame recommendations on the lines which were foreshadowed in the report of the London University, and to endeavour to strengthen that University, and the veterinary profession which dealt with animal pathology generally, by linking up various Colleges and Institutions with the University of London, and by giving the University of London and those Colleges larger funds to work with.

A few months ago he had received at the Board of Agriculture a very influential deputation from the University of London, which represented the great difficulty of maintaining one of their subsidiary institutions, namely, the Brown Institute, which, in the opinion of very eminently qualified authorities, was doing valuable work in the pursuit of animal pathology. This gave an example of the need which was felt all over the field of their operations for additional support to institutions for veterinary education and research. Secondary and advanced educational institutions could not be maintained without some kind of endowment, whether State or private. There were from time to time persons who would endow such institutions as the Lister Institute, but in many branches of necessary education for the advancement and maintenance of the interests of the State they must depend more and more upon assistance from public funds, and he rejoiced that Parliament had had sufficient forethought to establish a Development Fund from which such institutions as instructed the veterinary profession could hope to have some assistance.

There was some apprehension that the motor development of the carriage and mechanical traction would displace a great part of the animal creation to which their attentions had been greatly devoted, but it was ridiculous to suppose that the motor industry would affect the whole stock breeding industry of England. He believed as much attention was being paid to stock breeding as ever, and that in the future more attention would be paid to it. They had for years led the world in stock breeding, and they were not going to abandon that lead. We must make a point of maintaining the health and increasing the security of their flocks and herds, our heavy horses, racehorses, and hunters, and those kinds of horses would be by no means extinguished by any development of motor traction. The matter of stock breeding was receiving as much, and even more, attention from the public and the Board of Agriculture than it had before. There was a demand that these valuable animals should be properly tended and cared for, and those who devoted themselves to that branch of activity would be well rewarded. In England they were at the present time bringing the veterinary interests more into line with the ordinary medical interests than had been done before. They had not only attempted to deal with such comparatively insignificant diseases as anthrax and glanders, which were inimical to the human subject, but they had joined hands in dealing with tuberculosis. In regard to glanders, he was sorry the Government had not seen its way to complete, or allow the veterinary profession to complete, the work which had been done by the local authorities in the administration of the laws for the suppression of glanders. The local authorities had done a great deal, and spent much money in stamping out that disease in their localities, and had confined the disease to such measurable limits that, so far as the home-grown disease was concerned, it could probably be extinguished, but it was still liable to be imported from abroad. In the opinion of the Board of Agriculture it was unfair upon local authorities that they should have to deal with the whole of the inspection and regulation of the imported horse trade, which went through certain ports to all parts of England. He regretted that the English Government—and he spoke of it collectively—had not found it possible to place at the disposal of the Board of Agriculture the necessary funds to provide inspectors to carry out the regulation of the imported horse trade so as to stop the increase of glanders, and thus complete the work which local authorities had done in dealing with the disease. The Government had passed an important Tuberculosis Order in advance of the Milk and Dairies Bill. He did not blink the fact that from time to time erudite and resolute men assured him that the whole of the Tuber-

culous Order was founded on a mistake, but if there was still any doubt, that was one of the points upon which the profession had to make up its mind—was tuberculosis, or was it not, communicable from bovines to man? They were acting under the belief that it was communicable, and so long as they thought it was, they felt it their duty to come in aid of the medical profession and do their best to stamp out the plague. If there was any uncertainty upon the matter, was it not evidence of the need for further promotion of veterinary study and work in their laboratories—for which they were asking for further assistance from the State, in order that their Colleges and laboratories might settle such questions? More and more they were coming to realise that veterinary science must become fused with the general pathological study of the human and animal races, and must co-operate to determine such questions. In that direction there were just as great openings for the exercise of genius, and for the rewards of genius, in the veterinary medical branch as there were in any other branch of the profession. They regarded the whole of the study of pathology as one. Those who had specialised in animal pathology were not going to help them simply with regard to the diseases of sheep and cattle, but were going to help in the general development regarding the national life depending upon the health of men, women, and children, and the animals with which they consorted, and on which they depended for their happiness, life, and sustenance—a body of creatures whose lives and health depended upon one another.

He coupled with the toast the name of a most distinguished and admirable member of the profession—Sir John M'Fadyean—to whom the Board of Agriculture and the kingdom owed a great debt of gratitude. (Cheers).

[The toast was duly honoured].

Sir JOHN M'FADYEAN, LL.D., who was received with loud cheers on rising to respond, said he joined in the regret that had already been expressed that Mr. Carter was not present to respond to the toast. Had Mr. Carter been present he (the speaker) was sure he would have begun by saying what a great pleasure it was to all of them to have Sir Sydney Olivier with them that night. (Cheers). It was a great gratification to them that Sir Sydney Olivier had consented to propose the toast, and he had proposed it in terms which showed his appreciation of the services which their profession was capable of rendering to the great national industry of Agriculture. There were some things connected with the Royal College of Veterinary Surgeons which he thought Sir Sydney did not know, although he could not help being struck with the remarkably comprehensive grasp which Sir Sydney had already taken of the duties and functions of that profession. The Royal College of Veterinary Surgeons had a most democratic form of government. The domestic affairs of the profession were managed by a small Parliament of 32, who were elected by universal suffrage on the principle of one man, one vote. (Hear, hear). Every member of the profession who was accessible by post had an opportunity of voting at every election. The provisions of the Charter compelled one quarter of the members of the Parliament to retire annually, and it was thus possible for the electorate in the course of four years to absolutely change the composition of the representative body, and in half that time to absolutely dispose of any possible majority. Provision was thus made for securing that the will of the electorate with regard to domestic veterinary matters should prevail. He regretted that there was one matter on which the Royal College remained determinedly Conservative—it would not consent to pay its elected representatives. (Laughter). Although as a rule people did not like to be taken too seriously in after-dinner speeches, he was sure they would all feel in future that they had in Sir Sydney at the Board of

Agriculture one who was well-disposed towards them. (Hear, hear, and cheers). Sir Sydney would, he hoped, always be disposed to help them in any matter in which he felt satisfied that their interests and the public interests, and more particularly the interests of stockholders in this country were not in opposition. During his twenty years membership of that small parliament he had plenty of opportunities of gauging the manner in which the members of Council did their work and the impulses that moved them, and he ventured to say it would not be possible to find any similar body of men who did their duties with a more single-minded purpose, to promote the public interests. Their constant aim had been to join with the various teaching colleges in order to provide this country with the necessary number of veterinary surgeons educated up to the highest possible degree in all that related to the diseases of animals. The Council recognised that they had a function outside that of merely endeavouring to prevent or cure the diseases of domesticated animals; they felt that they had a not insignificant part to play in conserving human health. Sir Sydney had alluded to that in very eloquent terms, and had referred more particularly to the work which now devolved on veterinary surgeons in connection with the administration of the recently introduced Tuberculosis Order. He was a little surprised to find to find that Sir Sydney had some slight doubt as to whether bovine tuberculosis was communicable to man or not. He (Sir John) was under the impression that the important Royal Commission, on which medical and veterinary science were represented, had proved that beyond the shadow of a doubt; but if there still was a doubt as to whether tubercle bacilli coming from the udders of diseased cows could cause tuberculosis in children, then in his opinion it was the children and not the cow that ought to have the benefit of the doubt. (Hear, hear, and cheers). There was no ground, whatever, for staying the proceedings of the Tuberculosis Order until this doubt had been removed.

The Council of the Royal College of Veterinary Surgeons had always regarded it as its main duty to provide the country with properly qualified veterinary surgeons, but it was also their duty to protect the public from the deception which arose through uneducated and unqualified people taking to themselves the title of "veterinary surgeon." Both those duties were plainly laid upon the Royal College by its Charters and by the Veterinary Surgeons' Acts, but when those duties were imposed, it was not foreseen that it might involve an expenditure for which the assigned resources of the Royal College would not be sufficient. But that was what had actually happened, and as a consequence the insolvency of the Royal College of Veterinary Surgeons was a matter of certainty within a comparatively near period unless some means of increasing its income could be provided. It was in what he ventured to call a spirit of commendable self-sacrifice that the College agreed to tax themselves to provide the necessary money, and that was really almost the whole of the power that was sought in the Bill which, as Sir Sydney had reminded them, had been twice before Parliament without reaching the second reading. They would all go home cheered by what Sir Sydney had said with regard to that Bill; they were now quite assured that they had his sympathy, and he expressed the hope that the influence of the Board of Agriculture might be employed to induce the Government to give their support to the Bill when it was introduced into the next session of Parliament. (Loud cheers). In conclusion, he thanked Sir Sydney for having proposed the toast in such a kindly and sympathetic manner, and also thanked the Fellows for the hearty way in which the toast had been drunk. (Cheers).

Mr. T. SALUSBURY PRICE, on rising to propose the toast of "The Past-President" (Mr. McIntosh), said he

felt rather reluctant after the speeches of Sir Sydney Olivier and Sir John M'Fadyean. We now know if the veterinary profession requires to be uplifted or benefitted in any way, and if Sir Sydney can do it he will, as his speech denotes such a friendly feeling towards the advancement of the veterinary profession, and after such speeches I feel at a discount in standing here to propose the toast of the Past-President. I understand Mr. McIntosh has been a member of the Central Veterinary Association for about six years, and I wonder how it is that a new member should make such a rapid advance. I was a member of the Central for twenty-five years before I became President, but Mr. McIntosh did it all in six years. I don't know, unless it be that he comes from the north. (Applause). I also understand that he was one of the Governors of the Dick College for several years. He was also the President of one of the Scottish Associations for two or three years, and also on the Council of one of the municipalities of Scotland, and I expect and hope he will soon become one of the Mayors of London. They all knew that the Past-President had done remarkably well. The Past-President was what he called a stout President. (Laughter). This year they had a thin President, but after this year he was sure they would be satisfied with Professor Wooldridge's presidency as they had been with Mr. McIntosh's. Next year would be a grand year for the veterinary profession to show its colours; 1,200 to 1,400 members were coming to the Congress from all parts of the world, and a fund of £5,000 was required to make the Congress a success. £3,200 had been subscribed by about 300 veterinary surgeons, and there were 2,700 veterinary surgeons who had not yet been tapped, but he understood Mr. McIntosh and some other members of the profession were busy tapping them, and he wished them luck. He asked them to drink to the health of Mr. and Mrs. McIntosh and to wish them long life and happiness, and that health and prosperity would go with them wherever they went. (Cheers).

[The toast was accorded musical honours].

Mr. J. W. MCINTOSH, in responding, said when the Fellows placed him in the chair twelve months ago he recognised in that honour great responsibilities—responsibilities which he accepted with a certain amount of misgiving. That feeling, however, soon disappeared, because of the warm support and courtesy extended to him by the Fellows. In their expression of approval of his efforts to uphold the usefulness and dignity of the office he felt sufficiently rewarded. It had been a great pleasure to him to preside over the members of the Central Veterinary Society, and although reduced to the ranks again, he hoped he would be still able to give that support to the chair and to the Association which every member ought to give. (Hear, hear). He wished success to the new President, and offered his sincere thanks to the Fellows for their support and their forbearance, and to the office-bearers who assisted him in his efforts, he acknowledged himself profoundly indebted, and profoundly gratified. (Cheers).

Professor J. MACQUEEN, in proposing the toast of "The Ladies," said that he felt in a very peculiar position, because he did not remember ever having had to propose this toast before. He had very little experience of ladies, and might repeat the reply of the boy to his aunt when she said to him, "Teddy, don't you think you are getting rather too old to play with the girls?" "No, auntie, the older I get the better I like them." That was his experience, so far as it went. (Laughter). A lady advocate of women's rights, who got on a platform to make a speech, began by saying "Why am I here?"—a long pause—"Why was I born?"—another pause—and then a boy in the gallery said, "We give it up." (Laughter.) He did not know why he had been selected to propose that toast, but he would give an

indication of what he might have said if there had been more time. He was going back to the days of Adam. There was a great deal to be said about Adam. He was referring to Adam when he was working quietly on his allotment—(laughter)—and probably anticipating some of Mr. Lloyd George's reforms. Adam was ably seconded by Eve. Eve had her troubles no doubt, but she was a pioneer of hygienic clothing, and in the 20th century they were beginning to realise the importance of too much clothing. (Laughter.) In those days it was discovered that it was not good for man to be alone, and he supposed that that was the reason why the toast of "The Ladies" was now so frequently introduced. A distinguished and religious Frenchman had said that a beautiful woman was Hades to the soul, purgatory to the purse, and Paradise to the eyes. (Laughter.) He (the Frenchman) was not acquainted with veterinary ladies or he might have reversed the order of his estimate. (Cries of "Oh," and laughter.) There were many things he might have said about the ladies, but he could see that gentlemen present had had ample experience of the ladies themselves, and they would be able to form their own opinion and their own estimate. (Hear, hear, and laughter.) There was a certain responsibility attaching to the toast, though it was, perhaps, not the same sort of responsibility that appealed to the farm boy who was in the habit of receiving Sunday lessons from the farmer's wife. The farmer's wife asked him, "Tom, what is responsibility?" and after a deal of consideration the boy replied, "It is when my breeks are held up with one button and a pin." (Laughter.) He would ask all those present, gentlemen batchelors, bachelors, monogamists—(laughter)—misogamists, and polygamists (if any such were there), in drinking to that toast to make their practice fit the precept, and not to follow the lead of a certain alleged teetotaler. The teetotaler, he need hardly tell them, was a Scotsman—(laughter)—and it was noticed from his bearing and rubicund countenance that there might be good ground for suspecting that he was unfaithful to his pledge. The result was that the Timothy's of temperance made enquiries, they brought the old man before them and asked him if he ever indulged at all. "Na, na," he said, "What I do is to put a wee drop of whisky into the bottom of the tumbler just to warm it, but you ken I never drink down to the whisky." (Laughter.) He hoped that in response to the toast they would not imitate the old Scotsman, but would drink heartily to the ladies, who were their charming friends, and with the toast he coupled the name of a very charming lady, Mrs. John Willett, the wife of a prominent member of the Central Veterinary Society.

Mrs. JOHN WILLETT, in responding to the toast, said she received great enjoyment from such happy evenings, and only regretted that the Society did not ask the ladies more often. If the gentlemen would only arrange a ladies' night once in three months, the ladies would willingly accept the invitation, and, apart from that, they would know that their husbands went straight home. (Laughter.) She had heard several ladies wished to become veterinary surgeons. Personally, she preferred to be a veterinary surgeon's wife, and she was quite sure they could all help the profession a great deal in their own homes by assisting their husbands and brothers, because the ladies wished them to feel they were really their helpmates, and not merely women to look at. (Hear, hear.) On behalf of the ladies she thanked Prof. Macqueen for his kindness in proposing the toast, and for all the pretty things he had said about them, and also the gentlemen for the warm and hearty manner in which they had received it. (Loud cheers.)

Mr. W. R. DAVIS, in proposing the toast of "The Visitors," said that he hoped that the visitors had spent an enjoyable evening, and he assured them that their presence had added to the enjoyment of the members.

(Hear, hear.) Somebody had said that there were sentiments woven into the texture of our nature, some of them as old as the understanding itself, such as reverence and awe, and the religious feeling, but he thought hospitality might also be classed among those sentiments. (Hear, hear.) The demand for the satisfaction of that feeling of hospitality had been more than met by finding so many distinguished and fair visitors there that evening. (Cheers.) The sentiment of hospitality had, like other sentiments which were part of one's nature, been used as a cloak for crimes and cruelties. They had an example of that in their own country in Edward the Martyr, who, when offered a drink, had a knife stuck into him while quaffing it. He did not know whether Edward the Martyr was called a martyr on account of the way he died, but if all the men who died drinking were canonised, then there would be more saints than niches. He coupled with the toast the names of Dr. R. Leiper and Mr. Wooldridge.

Dr. R. T. LEIPER, in responding to the toast, thanked the Fellows sincerely for the very kind and generous hospitality which had been shown to the visitors that evening. There was an old saying that wine, women, and song made the heart glad, and he was quite sure that the hearts of their visitors were simply dancing with enjoyment. He felt he must allude to the loss the profession had recently sustained in the death of Mr. Hunting. Mr. Hunting was exceedingly kind to him years ago in helping him to get into touch with the veterinary profession, as Secretary of the National Association. The subjects of tropical medicine and veterinary science were very fortunate in each having had a personal leader. The whole modern movement of tropical medicine had been due to the personal inspiration of Sir Patrick Manson, and the veterinary profession had been equally fortunate in having Sir John M'Fadyean as their leader. Wherever he had gone in the tropics he had heard references to the inspiration of Sir John M'Fadyean in veterinary work. The visitors appreciated very heartily the hospitality which had been shown them. (Cheers.)

Mr. F. R. WOOLDRIDGE (brother of the President) who also responded to the toast, said he felt that he had been included in a previous toast. Someone called out for a cheer for "the little Wooldridges," and he thought that included him. (Laughter.) But as their President in his reply seemed to take it that it referred to the pug and the cat, he was not quite sure where he stood, and so far as he was concerned he had better therefore leave it alone. (Laughter.) He felt it a great honour to be present that evening and to see such a splendid gathering. He represented an entirely different phase of society from the veterinary or any other science which appealed rather to the body; he represented a profession which had to do more with the soul, the artistic profession. The artistic profession went further back than any of the other professions could possibly think of, over 30,000 years. In the British Museum it would be found that artists had given in their language some of the finest representations of animals in the world of the type which were then inhabiting the world—he spoke of the Stone Age with its most wonderful carvings on ivory and bone. They might think that art had nothing to do with veterinary science, but art had to do with everything in life. Without art the veterinary surgeon would not be able to exist as such, and he would not be able to get through his study without it, while his books depended upon the artist for illustrations. Again he thanked them for the very pleasant evening he had spent with them.

During the evening an excellent musical programme was rendered by Miss Bessie Jones, Miss Edith Estherley, Mr. Archie Anderson, Mr. Geo. Blackmore, and Mr. Thomas Noakes.

HUGH A. MACCORMACK Hon. Sec.

ANNUAL REPORT OF THE PUNJAB VETERINARY COLLEGE.—By COL. H. T. PEASE, Principal.

[ABSTRACT]

Col. H. T. Pease, C.I.E., was in charge of the office of Principal and Professor of Medicine during the year. Mr. S. H. Gaiger, the Professor of Sanitary Science, was granted an extension of leave on medical certificate, and was absent during the whole year. Mr. R. Branford was transferred to Hissar. Major G. K. Walker was appointed Professor of Sanitary Science in June, 1912.

Fifty-two students were admitted on the 20th April, 1912, and with five remanded formed the first year's class of fifty-seven.

There were fifty-nine students in the second, and sixty-six in the third year classes.

In June, 1912, six final year's students who had been remanded were examined and passed. Fifty-seven students appeared in the first year's examination, and fifty-four or 94.7 per cent. passed. Fifty-eight were examined in the second year's class, and 47 or 81.03 per cent. passed. Sixty-six students of the final year's class were examined by the Board of Examiners in April, and fifty-six or 81 per cent. obtained the diploma.

The results of the examinations are satisfactory, and show a considerable improvement over last year. The percentage of passes is high considering the very large classes which have to be taught.

Besides the ordinary work of teaching veterinary assistants, a class of dressers from the Transport Department was held during the summer vacation, and fifty men were trained.

A class for the training of farriers was also held, and twelve men were trained practically and passed the examination.

The demand for graduates is still very great, and though our classes are far too large, we are unable to meet it. The scheme put forward and sanctioned for providing means of increasing the number of graduates from this College is being reconsidered, but no decision has so far been arrived at. In the meantime we are keeping our classes at about sixty, which is too large.

The training in some of the subjects taught has been greatly hampered by lack of accommodation. The want of a dissecting room has again been very badly felt, and the results in the examination in this subject have not been at all satisfactory. The laboratory building has also not been extended, and the present accommodation is totally inadequate.

The Principal's and the translator's spare time has been occupied in re-writing the text-book on Equine Medicine, which is now in the press.

A new edition of "Principles of Horse Shoeing" has been published by them during the year.

I am glad to say that the prospects of veterinary assistants in the Transport Department have been materially improved and may now attract some men to that service.

His Honour has selected a site for the new College, and plans and estimates for the proposed buildings have been prepared and submitted to Government.

As usual, the staff have worked loyally and well, and I think take some pride in the progress of the institution. I am glad to say that Raja Ghulam Hussain Khan, one of our old teachers, has at last been rewarded for his service by the grant of the personal distinction of Khan Sahib.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Tuberculin at the Perth Sales.

"A feature of the sale was the fact that all the bull calves from the three expositors had been subjected to the tuberculin test, and the results were announced by the auctioneer in every case. In no instance, save perhaps one, could a re-acting calf be started above 25 gs., and the cases were rare in which prices at all in agreement with the merits of the animals, apart from the results of the test, were obtained."

"The cause of this significant change of front on the part of the Northern breeders is said to have been the results of last year's sales. It is currently reported that two of the highest-priced bull calves sold last year for export have not gone out of the country. They reacted to the test, and it was useless to ship them. . . . Hence the fact that almost all the bull calves sold on Tuesday were tested by Mr. Manuel, whose charts were handed over to the buyers when desired, and their results were announced in every case."—*The Scottish Farmer*.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Lieut. J. G. Coleman to be Capt. Dated Aug. 11th.

OBITUARY

GEO. WM. TENNANT, M.R.C.V.S., Newcastle-on-Tyne.
Graduated, Edin: July, 1882.

Mr. Tennant died on Nov. 24th from cirrhosis of the liver, ascites. Aged 56 years.

THE LATE SIR GEORGE BARHAM.

Sir George Barham died on Sunday, 16th inst., at Snape, Wadhurst, one of his estates, in the county of Sussex. Sir George Barham, or plain Mr. Geo. Barham, as he then was, first came into prominence in London

in 1865 about the time of the cattle plague. He was then a dairy keeper in the City, and London being threatened with a milk famine he set himself to import large quantities of milk into London from the country districts, and did much to develop country milk trade even in late years. The introduction of modern dairying in India was also the outcome of Sir George's public-spirited action in sending out, at his own expense, a Commission of experts, equipped with the most improved scientific and mechanical appliances, to give demonstrations in modern hygienic dairying methods. As a member of the Committee on Milk Standards in 1900 he issued a minority report, the essential features of which were adopted by the Board of Agriculture. Sir Geo. Barham took an active part in philanthropic work, and founded the Metropolitan Dairyman's Benevolent Institution. A self-made man, he started in the dairy business in a small way, and rose by his own energy and exertion, and as Chairman of the Dairy Supply Co., Ltd., and the Express Dairy Co., Ltd., he controlled two of the largest dairying companies in the Metropolis, and was a leading supporter of the British Dairy Farmers' Association, while on three or four occasions he presided at their annual conferences. He received in 1904 the well-deserved honour of knighthood for his services.—*N. B. A.*

Hon. Sec. & Treas: Mr. Sidney Smith, JUDR., M.R.C.V.S.,
37 High Street, Lowestoft
Meetings, Second Tuesday, Feb., July and Sept.

LINCOLNSHIRE AND DISTRICT V.M.S.

Pres. Mr. C. W. Townsend, F.R.C.V.S.,
Long Stanton, Cambridge
Hon. Sec. & Treas: Mr. Tom Hicks, M.R.C.V.S.,
Boston Road, Sleaford
Meetings, Second Thursday Feb., June, and October

ROYAL COUNTIES V.M.A.

Pres: Mr. David Wyllie, M.R.C.V.S., Tudor House, Staines
Hon. Sec. & Treas: Mr. G. P. Male, M.R.C.V.S., Reading
Meetings, Last Friday, Jan., April, July and Nov.

SOUTHERN COUNTIES V.S.

Pres: Mr. G. H. Livesey, M.R.C.V.S., Hove, Sussex
Hon. Sec: Mr. A. H. Archer, M.R.C.V.S., Southsea, Portsmouth
Hon. Treas: Mr. E. W. Baker, M.R.C.V.S., Wimborne
Meetings, Last Thursday, Mar., June and Sept.

SOUTH EASTERN V.A.

Pres. Mr. James Crowhurst, F.R.C.V.S., Canterbury
Hon. Sec. & Treas. Mr. Theo. C. Toope, M.R.C.V.S.,
34 High Street, Dover
Meeting, Second Wednesday in September, Ashford

WESTERN COUNTIES V.M.A.

Pres: Mr. C. E. Perry, F.R.C.V.S., Staple Hill, Bristol.
Hon. Sec. Mr. W. Ascott, M.R.C.V.S., Bideford
Hon. Treas: Mr. P. G. Bond, M.R.C.V.S., Plymouth
Meetings, Third Thursday, March, July and November

Irish Branch:

Pres. Mr. W. Watson, Municipal Buildings, Dublin
Sec. Mr. P. D. Reavy, Leafield, Bundoran, Co. Donegal

CENTRAL V.A. OF IRELAND.

Pres: Mr. B. P. J. Mahony, M.R.C.V.S., Maryborough
Hon. Sec. Mr. E. C. Winter, F.R.C.V.S., Queen-st., Limerick
Treas: Mr. J. F. Healy, M.R.C.V.S., Midleton

CONNAUGHT V.M.A.

Pres. Mr. D. Hamilton, M.R.C.V.S., Ballina
Hon. Sec. & Treas. Mr. A. J. Moffett, M.R.C.V.S., Galway

VET. MED. ASSN. OF IRELAND.

Pres: Mr. P. J. Howard, M.R.C.V.S., Ennis
Hon. Sec: J. J. O'Connor, M.R.C.V.S., R.V. Coll., Dublin
Hon. Treas: Prof. J. F. Craig, M.A., M.R.C.V.S.,
R.V. Coll., Dublin

NORTH OF IRELAND V.M.A.

Pres: Mr. J. A. Jordan, M.R.C.V.S., Belfast
Hon. Sec: Mr. J. Ewing Johnston, M.R.C.V.S., Belfast
Hon. Treas: Mr. J. A. Thompson, F.R.C.V.S., Lurgan

Scottish Branch:

Pres. Dr. O. Charnock Bradley, } Ryl. (Dick) V et.
Hon. Sec. Prof. A. Gofton, } Coll: Edinburgh

NORTH OF SCOTLAND V.M.S.

Pres: Mr. W. Marshall, M.R.C.V.S., Aberdeen
Hon. Sec. & Treas: Mr. G. Howie, M.R.C.V.S., Alford, Aberdeen
Meetings, Last Saturday in January and August

ROYAL SCOTTISH V.S.

Pres: Mr. Reid, M.R.C.V.S., Auchtermuchty.

SCOTTISH METROPOLITAN V.M.S.

Pres: Mr. J. Riddoch, M.R.C.V.S., Edinburgh
Hon. Sec. & Treas: Mr. Jas. Henderson, M.R.C.V.S.,
Public Health Dept., City Chambers, Edinburgh

WEST OF SCOTLAND V.M.A.

Pres: Prof. John R. McCall, M.R.C.V.S., Vety. Coll. Glasgow
Hon. Sec: Mr. J. F. Macintyre, M.R.C.V.S.,
19 Bank Street, Hillhead, Glasgow
Hon. Treas: Mr. Geo. W. Weir, M.R.C.V.S.,
88 Crookston Street, Glasgow
Meetings, Second Wednesday, May, Oct. and January.

COLONIAL SOCIETIES: (see preceding page)**CAPE OF GOOD HOPE V.M.S.**

Pres. Mr. J. D. Borthwick, M.R.C.V.S., Cape Town
Hon. Sec. & Treas. Mr. R. W. Paine, F.R.C.V.S.

CENTRAL CANADA V.A.

Hon. Sec: Mr. A. E. James, Ottawa
VET. ASSN. OF MANITOBA.
Pres: Dr. W. R. Taylor, Portage la Prairie
Hon. Sec. & Treas: Dr. F. Torrance, Winnipeg

NATAL VETERINARY MEDICAL ASSOCIATION.

Pres. Mr. F. J. Carless, M.R.C.V.S., Mooi River
Hon. Sec. & Treas. Mr. A. W. Shileston,
Vety. Research Laboratory, Pietermaritzburg

ONTARIO V.A.

Pres: Mr. J. H. Tennent, V.S., London, Ontario
Sec. & Treas: Mr. C. H. Sweetapple, V.S., Toronto, Ontario
TRANSVAAL V.M.A.

Pres: Mr. C. E. Gray, P.V.S., Box 134, Pretoria.
Hon. Sec: Mr. P. Conacher, V.S., Box 877, Johannesburg

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1326.

DECEMBER 6, 1913

VOL. XXVI.

PROFESSIONAL ASSOCIATIONS.

An item of news from abroad shows us how recent a growth the veterinary development of this country is, compared with that of some Continental ones. A few weeks ago the Society of Swiss Veterinary Surgeons celebrated its centenary, and, small as Switzerland is, its National Veterinary Association numbers 400 members.

No veterinary society in this country is anywhere near its centenary. Jubilees of local societies will be not uncommon before long, but hardly any man now on the Register will see his local society celebrate its centenary, and probably not one will see our "National" do likewise. It is no great exaggeration to say that our recognition of the value of professional associations is a growth of the last half-century, though no one who sees the present number and vigour of our societies would suppose so. We are making up for lost time.

One of the healthiest signs in our professional life to-day is the continuous development of our associations. Their recent union with the "National" should greatly increase their power, but it will be some time yet before the union is in full working order, and a great deal will depend upon what steps are taken to make it so. The local societies preserve their independence, and may be relied upon to lose neither vitality nor utility. But to bring the larger "branches" and the whole body of the "National" to their full possible measure of utility will require energy and discretion combined.

SOME SECONDARY EFFECTS OF THE TUBERCULOSIS ORDER.

Indirectly, the Tuberculosis Order may exercise a considerable educative effect amongst clinicians. It has brought the centrifuge and the oil immersion lens into frequent use in many practices: and this may lead to a much more general recourse to high-power microscopy than has yet been common amongst us. Again, the Tuberculosis Order will make some practitioners more minute and thorough in their clinical examinations than heretofore—as, for instance, in auscultation. Auscultation of the lungs in the larger animals has been much neglected by clinicians, simply because many of them doubt its reliability. Most of these, under the Tuberculosis Order, will give it a new and more careful trial. The whole effect of the Order will tend to improve and refine our everyday methods of diagnosis: and the improvement will by no means be confined to tuberculosis. It is too soon yet to expect much apparent evidence that this is taking place, but we do expect to see such evidence before very long.

ANTI-TETANIC SERUM.

By J. P. ISHERWOOD, M.R.C.V.S., Blyth.

Seeing reports of several cases of tetanus in last week's *Veterinary Record*, in which anti-tetanic serum was used as a prophylactic and otherwise. I thought this case I am recording might interest your readers.

On Saturday, Oct. 4th, I was asked to examine a bay draught mare, six years old and about 16.3 h.h. The mare was working at the time—taking a load of hay into the town. Apart from a slightly elevated temperature and a quickened pulse, she did not appear to have very much the matter with her, so I prescribed a fever draught.

On the Wednesday following, the owner's son called on me and told me the mare was not going on as they would like, and asked me to see her. He said she was constantly twitching her tail and seemed stiff all over.

I went up at once, and found her in the condition stated: the muscles all over the body were pretty rigid, the tail constantly twitching, and when backed—which was accomplished with great difficulty—this symptom was intensified, and the tail assumed the horizontal position.

Our attempts to administer a physic ball were utterly futile, as it brought on a violent spasm every time I tried to get hold of her tongue, and she nearly ran us down. The head being thrown up, with the membrana nictitans shot over the eye, almost completely covering it.

Fortunately I had one dose of Parke, Davis and Co.'s antitetanic serum at home, so I promptly went for it, and gave her the full dose hypodermically. I telegraphed for four more doses that night, received them next morning, and gave her a full dose (3000 units) daily, and three more doses after that, eight altogether; the last doses I divided into two, and injected one in the morning and the other at night. At the end of which time the tetanic symptoms were fast disappearing, and the mare nearly all right, though she did not work for three weeks.

The mode of entry of the germs was undoubtedly by a wound about the size of a penny when I saw it, though it had been larger—situated just behind the left ear. This was *very sensitive* to the touch at first, but after each injection it became less so, and after the tenth day she offered no resistance when it was dressed. The dressing used was a fairly strong lysol solution.

I may say the trismus was not a well-marked symptom in this particular case, and she managed to sustain herself on mashes, and even hay, during the whole time.

We were fortunate in getting a well darkened loose-box, well away from all noise, and she was only visited by one attendant.

In recording this particular case, one must remember we had almost everything in our favour. Firstly, the sub-acute character of the disease. Secondly, the ability to take nourishment. Thirdly, the evident potent action of the serum; and fourthly, the very favourable surroundings.

As a rule we are called in when our unfortunate patients are *in extremis*—or next door to it, and no serum, however scientifically prepared, can be of any use.

In conclusion, I may state that with the exception of mag. sulph. powders given night and morning, she received no other medicine than the anti-tetanic serum.

A CURIOUS ACCIDENT.

A large retriever which is very fond of retrieving was out with the footman, and a portion of an old ash walking stick, about 18 inches to 2 feet in length, with a crook handle, was thrown for the dog to fetch. All at once while running with the stick in his mouth the stick disappeared down the dog's neck with the exception of the handle. The footman seized the handle and with some difficulty pulled it away. There was some blood from the mouth, but he seemed otherwise little the worse for the mishap. Nothing apparently troubled him for about eight days, when he appeared very ill, showing symptoms of rigors and general disturbance, with loss of appetite and a temperature of 104.

On examining the mouth a large ulcerated wound on the left side of the tongue was found, and a large swelling near the situation of the upper part of the postea spinatus muscle. This proved to be a kind of cyst which was drained and syringed, and the dog made a rapid recovery.

The crook handle must have caught in the ground or a tuft of grass whilst he was running, and the impetus have been so great that the other end (somewhat pointed) was driven down under the tongue and through the cervical muscles to the shoulders. W. W.

A PUZZLE IN LAMENESS.

On Nov. 3rd I got a wire "come and see hunter lame." That afternoon I called and saw the horse, a six-year-old light hunter gelding, the property of a nobleman. I found him in his box quite comfortable and happy. While I stood to watch him for some minutes the groom informed me that the horse was taken off grass in September, and had been getting quiet exercise; that he started to go lame in front a week ago, and that he was sure the horse was getting "that navicular." I asked him to put a halter on and get the horse outside. The horse walked out perfectly, and to my surprise trotted perfectly sound. After trotting up and down several times he was still sound. The groom

said, "he was a cripple yesterday." I told the groom I could not see any sign of lameness, nor anything wrong to cause lameness. I advised that the horse get a few hours work next day and let me know again how he was.

In a few days I got a note that the horse was still lame. I called again, got the horse pulled out, and again found he went perfectly sound. I decided to have a ride and ordered the saddle on. Immediately the saddle was fixed the horse walked dead lame on the off fore.

I got on his back and he was almost paralyzed in the off-fore at a walk.

I took him to a paddock and found he could gallop sound, trot fairly sound, but a cripple at a walk.

I had the saddle removed, and again, to my surprise, the horse went absolutely sound at once. I put him in the lunge with a long rope, and had him trotted and galloped round and round in each direction, without any sign of lameness.

I got the saddle on again, and he at once went dead lame. Then I put up the groom without a saddle, and he walked dead lame, trotted not so lame, and galloped sound.

There is no sign of pain or tenderness on any part of the back, shoulder, or limb, and the horse has not been lame before. I know him over a year.

I concluded there was some nerve trouble (safe opinion) in the shoulder region. I advised hot bathing, massage, and absolute rest.

I have seen the horse twice since, and he goes perfectly sound till the slightest weight gets on his back, when he at once walks lame, though he is not much lame in trot, and can gallop sound.

I confess I am completely puzzled, and would be grateful for some help from your readers as to what is really wrong. I relate the case because it is a peculiar and rare one, and under ordinary circumstances one does not dream of having a horse ridden to see if he is lame.

Ennis.

P. J. HOWARD.

ABSTRACTS FROM FOREIGN JOURNALS.

LARYNGEAL TUBERCULOSIS IN THE OX.

Prof. Schlegel reports (*Zeitschr. für Tiermedizin*) a number of cases of bovine laryngeal tuberculosis, some of which were associated with open pulmonary tuberculosis. His observations have led him to the conclusion that tuberculous growths of the laryngeal mucous membrane often penetrate outwards between the laryngeal cartilages into the subcutis, so that the tuberculous new growths, ranging from the size of a bean to that of a chestnut, can be recognised in the living animal by direct palpation of the outer surfaces of the larynx. Schlegel regards this fact as important in practice.

The author also describes a case of laryngeal tuberculosis in a cow, associated with tuberculous ulceration of the trachea. In addition to laryngeal and pulmonary tuberculosis, ulcers ranging from the size of a pea to that of a shilling were found in

the mucous membrane of the trachea. Tubercle bacilli were found to be fairly numerous in these ulcers, and also in one upon the larynx.

For demonstrating the open nature of the lesions during life in these cases, Schlegel thinks that the best method is the now well-known one of introducing a tampon on a wire through a canula into the trachea.—(*Berliner Tier. Woch.*)

THE SALE OF FROZEN MEAT IN SWITZERLAND.

A decree of the Council of State (April 8th, 1913) regulating the sale of frozen meat in Switzerland, has superseded that of May 31, 1912. The following are amongst its provisions.

Art. 2. Requests for authority to sell frozen meats must be addressed to the Department of the Interior and of Agriculture. The authorisations are only granted temporarily, and will be withdrawn in the case of non-observance of the regulations.

Art. 4. Frozen meats must not be placed upon the market before being slowly thawed. With that object they should pass from the freezing chamber into the thawing chamber, and must not remain in the latter for more than five or six days.

Art. 5. Frozen meats should be sold in special places. Their sale, however, will be allowed in butchers' shops selling fresh meat, upon condition that the places permit a distinct exposition and a completely separate manipulation of the two qualities of meat. All the butcher's shops selling frozen meat should be provided with a cold, dry chamber.

Art. 6. A table of the prices of the different pieces of frozen meat shall be put well in sight in each place of sale.

Art. 8. The fee for inspection is 0.10 fr. for each 25 kilogrammes or fraction of 25 kilogrammes. (25 kilogrammes = about 55 lbs.—*L'Hygiene de la Viande et du Lait.*)

W. R. C.

MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the George Hotel, Northampton, on Thursday, November 13th. Mr. J. Martin, of Wellington, Salop, President of the Association, took the chair, and there were also present Messrs. A. B. Forsyth, Cannock; A. Over, Rugby; H. S. Reynolds, Daventry; W. H. Brown, S. J. Marriott, Northampton; E. Parks, J. Bainbridge, Wellingborough; J. M. Whyte, Tenbury; D. Forwell, Towcester; W. W. Grasby, Daventry; Brennan DeVine, Birmingham; P. Evershed, F. H. Gibbings, Nottingham; G. Wartnaby, Burton-on-Trent; F. L. Gooch, Stamford; W. H. Brooke, Handsworth; J. J. Burchnall, Barrow-on-Soar; and the Hon. Sec. (Mr. H. J. Dawes, West Bromwich.)

The visitors present were Dr. Percival, Northampton; Mr. A. W. Noel Pillers, Liverpool; and Mr. W. H. Brown, South Kensington.

Apologies for unavoidable absence were received from Profs. McCall, Penberthy, Hobday, Messrs. L. W. Heelis, R. C. Trigger, J. W. Coe, T. Slipper, Shipley, Clifford, Burndred, R. Hughes (Oswestry), H. B. Hiles, R. Cock-

burn, C. E. Dayus, F. V. Steward (Hereford), W. S. Carless (Worcester), T. Chambers (Dudley), E. Ringer, J. Martin, Jun. (Newport), J. R. Carless (Shrewsbury), E. H. Woodcock, G. Smith (Tunstall), J. Malcolm, H. Thackeray, Crofts, and others.

The minutes of the previous meeting were confirmed. *New Member.*—Mr. EDWIN HALL, of Wellington, Salop, on the motion of the President, seconded by Mr. DeVine, elected to membership of the Association.

Letters of Resignation.—The Hon. Sec. announced the receipt of letters from Mr. W. T. Brooke, of Warwick, and Mr. W. G. Burndred, of Hanley, tendering their resignation from the Association. Mr. Brooke gave as his reason the fact that he was shortly going abroad, and his resignation was accepted with regret. In the case of Mr. Burndred, it was ordered that the Hon. Sec. write to him with a view to inducing him to reconsider his decision.

Report of the Council.—The Hon. Sec. presented a report from the Council of the Association, which met prior to the general meeting. It was presided over by Mr. Martin, and there were also present Messrs. Burchnall, Brooke, Gooch, DeVine, Wartnaby, A. Over, Grasby, and the Hon. Sec. The Hon. Sec. announced to the Council that Professor Reynolds had promised, through Mr. Grasby, to give a demonstration at the next meeting of the Association, which being the annual meeting will take place in Birmingham, of some operations upon the dog. It was recommended that the local arrangements be left in the hands of a small committee, consisting of Mr. DeVine, Mr. Malcolm, and the Hon. Secretary.

The question of the payment of the affiliation fee of 1/- per member to the National Veterinary Association was discussed, and it was recommended that the Treasurer be instructed to pay the fee in respect of all members whose subscriptions have been received up to the end of June in each year, and the balance at the end of each financial year.

Mr. GIBBINGS moved that the report of the Council, together with the recommendations contained therein, be approved. This was seconded by Mr. Over and carried unanimously.

THE LATE MR. WILLIAM HUNTING.

The Hon. Sec. read a letter he had received from Mr. J. Malcolm relating to the lamentable death of Mr. William Hunting, and stating that he very much regretted his inability to be present to testify personally to the great loss which the profession had sustained by the death of Mr. William Hunting. Mr. Malcolm's words so admirably expressed the views of all of them that he (the Hon. Sec.) would like them recorded on the minutes of this meeting. Mr. Malcolm's letter was as follows:—

"Since the last meeting of our Association the veterinary profession has to mourn the loss of William Hunting, and I feel sure the Association will to-day send a resolution of our deep sympathy and condolence to his relatives. I regret exceedingly I cannot be with you to join in that resolution. He was one of our most honoured honorary members, one whom we all liked and loved, and in a sense idolised. And no wonder, for he was not only a great veterinarian but he was a unique personality, a rare being whom it did one and all good to know. He loved his profession intensely, and spent himself freely and without stint or thought of self in its well being. Throughout his professional life he was one of our real teachers. Always a searcher after truth, he kept on open mind on all debateable points, and there was nothing he appreciated more than an open mind upon unsettled subjects in others. The possession of this faculty he always attributed to the influence of his teacher, John Gamgee, but whatever Gamgee's influence was, there is no question that Hunting inherently

possessed this qualification. His writings in *The Record* brought weekly instruction, interest, and pleasure to all his readers, and all know how he travelled the country from end to end to attend veterinary meetings to lecture upon and discuss matters of interest to the members. And we can remember how we benefited by his illuminating talk, keen insight, logical deductions, and terse, explicit, lucid exposition of the subject under discussion. Literally a young man all his life, he revelled in meeting a young professional enthusiast, and discussing with him matters that seemed of vital interest or prime importance. In this way many of our best members, particularly in their early years, have been indebted to him for the valuable information and advice he so delighted to give. I shall never forget the first day, now over thirty years ago, I spent in his company. Having been three years with his father, I knew his own people and many of his early friends, both personal and professional. When I left him that night I thought him in many senses the most remarkable man I had met. And when acting as secretary to the Hunting Testimonial Fund many of the letters I received showed that I was not alone in this view. These letters also revealed that he was held in the most affectionate regard by the profession."

The HON. SEC. (Mr. H. J. Dawes) said that Mr. Hunting was elected in the year 1888 as an honorary associate, and seven years later, namely in 1895, he served the office of President. A survey of the minutes of their meetings since Mr. Hunting had belonged to the Association showed how great a part he had played in their deliberations. He was very regular in his attendance for a number of years and read them several papers. A paper by Mr. Hunting always drew a large gathering, whilst his contributions to the discussion of papers read by other members were invariably a source of instruction and pleasure. If Mr. Hunting was at variance with the views expressed by an essayist, he expressed his own opposite opinion in a kind and sympathetic manner, which was one of his noblest characteristics. But in every sense of the term Mr. Hunting was a splendid man, and, as Mr. Malcolm had suggested, he possessed a personality which made him absolutely unique in the veterinary profession, not only respected but beloved by all who knew him. He (the speaker) remembered him as an examiner of students, and the more than friendly interest he always manifested in the work of young men just embarking upon their professional career, would be recalled by many of them. Now that he was gone, they had to mourn the loss of a brilliant practitioner, a ready writer, a deep thinker, and a man who from all standpoints had shed light and lustre on their calling. Such a man would be greatly missed, and his place in the councils of the profession would probably never be re-filled. He moved that a letter expressing the deep and abiding sympathy of every member of this Association be forwarded to his sorrowing relatives.

Mr. GOOCH said he took a melancholy satisfaction in seconding the motion. He was more than shocked to hear of Mr. Hunting's death, because it was only a few days before his last illness that he met him at a meeting of the National, when he was as bright and cheery as ever. They had lost in Mr. Hunting one whom they were proud to call a brother practitioner, and one who, as a clinician, was probably without an equal.

Mr. GIBBINGS, Mr. WARTNABY, and others having briefly endorsed the remarks of the previous speakers, the motion was carried *sub silentio*.

THE LATE MR. J. THOMSON, OF COVENTRY.

The HON. SEC. said he had the mournful duty to announce the death of yet another member of the Association, in the person of their esteemed friend and colleague, Mr. J. Thomson, of Coventry. They ought not

to allow the occasion to pass without recording their sense of the loss which the Association and the profession generally had sustained by the removal of a man of Mr. Thomson's high character, both as a practitioner and as a man of the world. He begged to move that Mrs. Thomson and family be informed by letter of the genuine regret they all felt at his decease, and of their sympathy with them in their bereavement.

Mr. A. OVER seconded the motion, which was agreed to.

THE INTERNATIONAL VETERINARY CONGRESS.

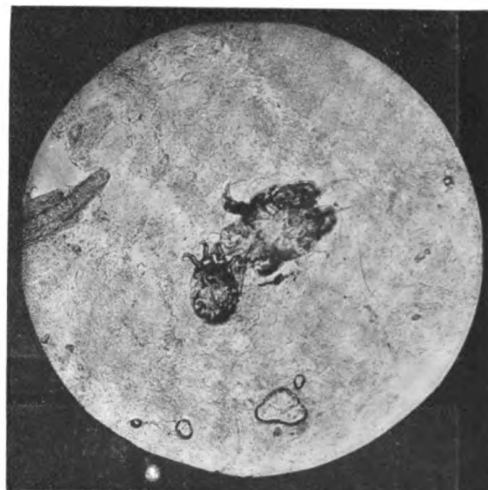

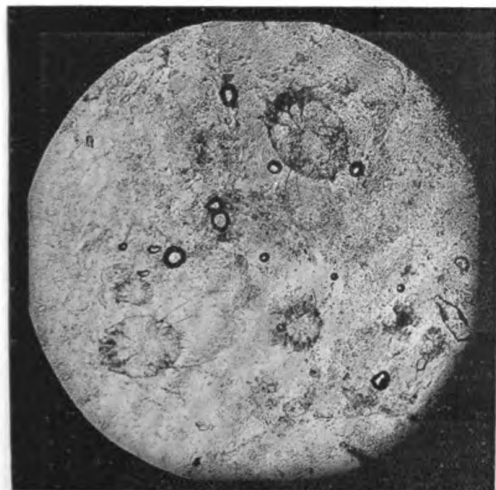

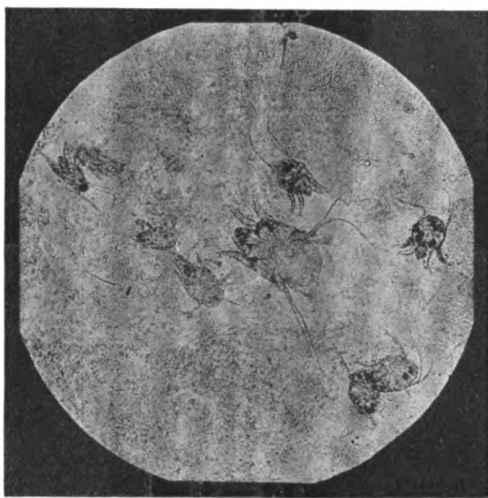

The HON. SEC. obtained leave to refer to this matter. He was sorry to say the appeal to members of the profession for financial support had not been as satisfactory as could have been wished. In a fortnight's time, he would be sending his list up to the Treasurer, and there were still a good many members whose names did not appear in it. Since the last meeting, he had received promises of a further £15, which brought up the total amount from members of this Association to about £370. He need scarcely remind them again that when the Congress met in other countries the governments of those countries made the local committees handsome subsidies. We in England receive no help or practically none from the State, and have to provide hospitality to the foreign delegates at our own expense. For the credit of the profession, we must see that in England the delegates are as well entertained as they were elsewhere. At present 30 or 35 members of the Association had not replied.

SOME ASPECTS OF MANGE IN HORSES.

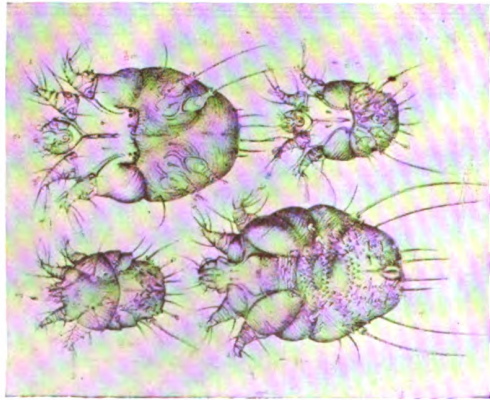

By A. W. NOËL PILLERS, F.R.C.V.S.

Mr. Chairman and gentlemen,—Last year, when I had the pleasure of reading before you a paper upon "The methods whereby parasites produce their injurious effects," great interest was shown concerning the many aspects of equine mange, and I promised at some future date, to offer for discussion some remarks upon that subject. I am now pleased to be able to fulfil that promise, confining my attention to the horse alone. Our standard text books, such as Neumann's "Parasites and Parasitic Diseases of the Domesticated Animals," Hutyra's and Marek's "Special Pathology," Law's "Veterinary Medicine," and Friedberger and Fröhner's "Veterinary Pathology," all contain so much information on the subject that I feel any remarks of mine will only be of the nature of a "tabloid extract" of the material contained therein. Our periodicals during the last few years have contained frequent references to the manges. In March, 1909, Mr. H. C. Harrison gave a short paper before the Lancashire Veterinary Medical Association on the Parasitic (Lancashire) Mange Order of 1908, and another paper was read by Mr. R. Bennett before the Central Veterinary Society in May, 1911. The most important contributions, however, have been by Sir Stewart Stockman and Mr. H. A. Berry in the Annual Reports of the Board of Agriculture and Fisheries for 1906 to 1909, and in *The Journal of Comparative Pathology and Therapeutics*. These latter papers refer to sheep scab, but they are of general interest with regard to certain of the mange mites. "The treatment of parasitic mange of the horse" was discussed in a short paper by myself before the Yorkshire Veterinary Medical Society on April 25th this year.

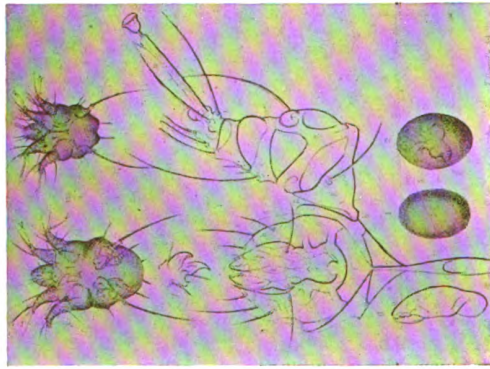

With this amount of literature before us, I do not propose to discuss the diseases in a systematic manner, but to mention only certain important interesting aspects which they present, some of which I shall be able to bring out better by means of lantern slides and specimens. We shall therefore consider briefly: (1) the position of the mange mites in nature and their syno-

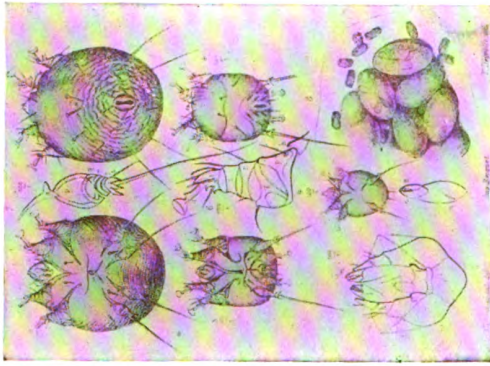

THREE SPECIMENS TAKEN IN ACTUAL DIAGNOSIS (*Pillers*).

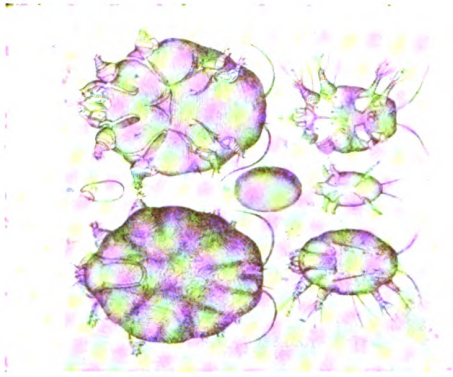

1. *Sarcoptes Scabiei*.—*Top left*, male, dorsal; *Right*, male ventral; dorsal; *Right*, male, ventral.

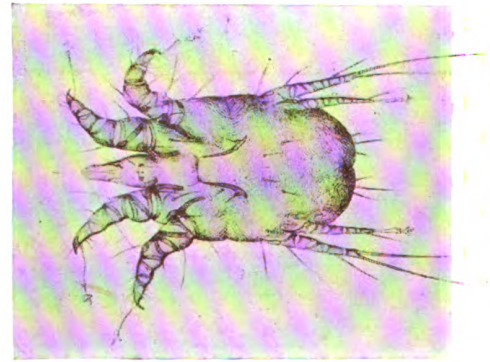

2. *S. Scabiei*.—Egg: egg with embryo; hexapod larva; octopod larva; rostrum and first leg: mandible.

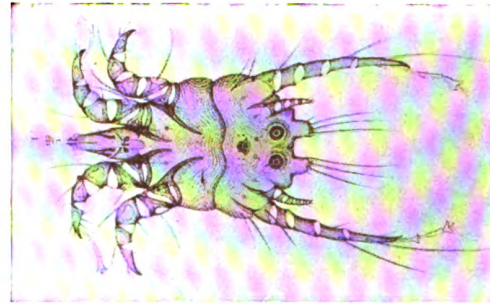

3. *S. notoedres*—var. *muris*.—Oviparous female, dorsal; dorsal; male, ventral; dorsal: a hind leg; a fore leg; rostrum; hexapod larva; portion of nest, eggs in various stages.

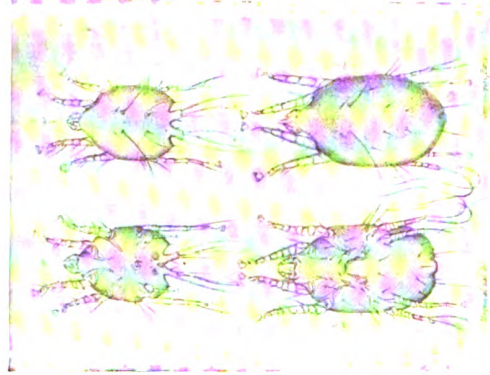

4. *S. Mutans*.—Oviparous female, dorsal; dorsal; male, dorsal; ventral; ventral: egg; hexapod larva.

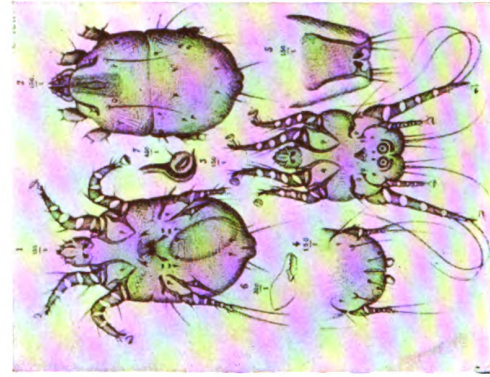

5. *Psoroptes longirostris*—var. *equi*. Oviparous female, ventral.

6. *P. longirostris*—Male, ventral.

7. *Chorioptes spathiferus*.—Male, ventral; dorsal; oviparous female, ventral; dorsal.

8. *Chorioptes ecaudatus*.—Oviparous female, dorsal; dorsal; male, ventral; dorsal: dorsal; male, ventral; posterior extremities of young female: of male, dorsal.

nymy; (2) the characteristics of the various genera; (3) a rough outline of their life histories; (4) their vitality, and go more fully into (5) the degree of parasitism; (6) seasonal occurrence; (7) parts affected; (8) diagnosis; and (9) principles of treatment.

The position of the mange mites in nature and their synonymy. Characters of the sub-kingdom, class, order, and family here given.

Kingdom	Animalia
Sub-Kingdom	Arthropoda
Class	Arachnida
Order	Acarina
Family	Sarcoptidae
Sub-Family	Sarcoptinae
Genera	
1. Sarcoptes	4. Psoroptes
2. Notoedres	5. Chorioptes
3. Cnemidocoptes	6. Otodectes

We recognise one species of each of three genera as occurring on the horse. Thus, we have sarcoptic, psoroptic, and chorioptic mange. The parasites are known by the following names:—

The sarcopt:

Sarcoptes scabiei var *equi*, Linne, 1758.
Acarus scabiei, Linne, 1758.
Sarcoptes equi, Gerlach, 1857.

The genus *Sarcoptes* was founded by Latreille, 1806.

The psoropt:

Psoroptes equi var *equi*, Hering, 1838.
Sarcoptes equi, Hering, 1838.
Dermacoptes communis, Fürstenburg, 1861.
Dermatodectes communis, Verheyden, 1862.
Psoroptes longirostris var *equi*, Megnin.
Psoroptes communis, var *equi*, Railliet, 1885.

The genus *Psoroptes* was created by Gervais in 1841; *Dermatodectes* by Gerlach in 1857; and *Dermacoptes* by Fürstenburg in 1861.

The choriopt:

Chorioptes bovis var *equi*, Hering, 1845.
Sarcoptes bovis, Hering, 1845.
Symbiotes equi, Gerlach, 1857.
Chorioptes caprae, Gervais and Beneden, 1859.
Dermatophagus symbiotes, Verheyden, 1862.
Symbiotes spathiferus, Megnin, 1872.
Chorioptes symbiotes var *equi*, Railliet, 1885.

The genus *Chorioptes* was found by Gervais and Beneden in 1859, *Symbiotes*, by Gerlach, 1857, and *Dermatophagus*, by Fürstenburg, 1861.

Anterior two pairs of legs marginal. Posterior two pairs of legs sub-abdominal. Males with no copulatory suckers or abdominal lobes.

Ambulacral suckers with a short pedicle on 1st and 2nd pairs of legs in both sexes, often on 4th in males. Parasitic in mammals.

Legs as above. Copulatory suckers may be present.

Ambulacral suckers on all legs in males. None in females. Anus terminal. Ovoviviparous. Parasitic on birds.

All legs marginal. Male bilobed extremity to abdomen. Copulatory suckers present. Parasitic on mammals.

Ambulacral suckers on the 1st, 2nd, and 3rd pairs of legs in male, and 1st, 2nd, and 4th in female. Long pedicle.

Ambulacral suckers on all legs in male. Short pedicle.

Anus terminal. *Sarcoptes*.

Anus dorsal. *Notoedres*.

(Mutans) *Cnemidocoptes*.

Psoroptes.

Chorioptes.

Otodectes.

(Illustrations from *Parasites Articulés*, Megnin).

The sarcopt is universally recognised as *Sarcoptes scabiei* *equi* or var *equi*; on grounds of priority, the psoropt should be known as *Psoroptes equi* var *equi*, but in this country it is usually designated *Psoroptes communis* *equi* or var *equi*.

For reasons of priority also the choriopt is known as *Chorioptes bovis* var *equi*, often, however, it goes by the name of *Chorioptes symbiotes* *equi* or var *equi*.

Rough Outline of the Life Histories.

[This slide shows at a glance the recognised life history of a psoropt, and from it the variations in the case of the sarcopt and choriopt can easily be pictured.]

Life History of Psoroptes.

Egg.	2—4 days (6—11)
Larva. (hexapod).	4 days
Nymph (octopod).	4 days.
Adult.	{ male. pubescent female.
	Ovigerous female.
Egg.	{ 7—30 during 8 days. 2—3 per day.

Characteristics of the various genera: The chief points which distinguish the various genera are shown in scheme at foot of page.

Inasmuch as we are only considering a single member of each of the genera, *Sarcoptes*, *Psoroptes*, and *Chorioptes*, those characters will be sufficient to distinguish the three species.

Vitality. From an epizootiological point of view, the time that a parasite is capable of living apart from its host is important. Gerlach obtained results which agree closely with those of to-day.

	<i>Sarcoptes</i> .	<i>Psoroptes</i> .	<i>Chorioptes</i> .
In crusts in glass dishes.	5 to 6	10 to 14	10 to 12 days.
In inhabited stables	12 to 14	20 to 30	40 to 50 "
On damp skin	24 to 25	42 to 45	— "

The degree of activity shown at the longer period in each case is often such as to be impossible for the parasite to regain life and become pathogenic. After a month, with thorough disinfection, harness, utensils, and stabling should possess little danger of infection. The resistance of the ovum is weak, and many do not hatch when again placed under favourable conditions, if the host has been left. Ideal conditions for incubation are entirely absent, apart from animals in habitations. We hear a great deal concerning "mange-ridden wood work," and stables which have "harboured" the disease for years, but animals carrying the parasite without showing any symptoms are the real culprits—at least this is so in the psoroptic form.

Degree of Parasitism. There is no doubt that the three species now under consideration are obligatory parasites. There are, however, many interesting points with regard to the degree of parasitism and injurious effects produced by mange mites. On account of the boring habit of the ovigerous female sarcopt, this mite always produces disease, but with the psoropt and choriopt the case is different. It seems probable that many recurrent outbreaks, recurrent attacks on the same individual, carter's who "always" have an affected horse, sudden appearance of the disease in resting horses, and seasonable prevalence of these two diseases, may be explained in terms of a varying degree of parasitism. In the working horse, one can never exclude the chances of daily infection. It is often reduced to a minimum, but how is one to explain the yearly manifestation of psoroptic mange on one and the same animal in a stud to the exclusion of others—and this although the affected animal may have been treated?

We have a similar state of affairs in the case of the large headed louse (*Hemattopinus maceroccephalus*). During certain months of the year, one may not be able to find a single louse on an affected animal's body, yet later on the host becomes swarmed. In such cases ova and adults can be found in the depths of the long hair of the legs. The next year's crop can be nearly ruined by treatment whilst there are no signs of lice on the body. I suggest that the psoropt often exists more or less as a commensal in the mane and tail. This is no doubt governed by a series of conditions, the removal of any of which causes the mite to produce lesions characteristic of the disease. An allied mite, *Cyrtolides nudus* or *Cyrtolidae*, often exists in the air spaces of birds without producing lesions, yet at other times it gives rise to the greatest inconvenience. A very like state of affairs exists with many other parasites, which only reproduce in their numbers under certain reduced conditions of their hosts.

Coming closer to the mange mites, there is a rarely recorded condition seen in thick-legged cart horses where an accumulation of fine, cellular detritus contains innumerable choriopts; there appears to be no stamping or other symptoms. In many cases of circumscribed psoroptic mange, such as those with a small patch on the withers or croup, I have found the parasite in the tail. It is, I think, possible for a horse whose skin is in the highest state of activity to harbour the parasite without showing symptoms. More likely is this if the weather remains mild. Certain factors break down this immunity. Thus, an unclean carter allows the parasite to increase and spread over the body, and if he be unfortunate enough to get three horses following with commensal mites on them, they will surely soon produce lesions. Yearly outbreaks on the same animal are explained in the same way. If treatment had been absolute all the mites would have been killed, but it is difficult to get a man to dress the mane and tail thoroughly, in fact it is often missed. Further, there is the protecting action of unremoved epithelial scabs to be taken into consideration, especially those of old lesions, the tail and mane. Recurrent outbreaks are

due to fresh infections, or more often to not applying so great attention to in-contacts as is really necessary, or to not dressing them at all, as they appear so spotless and far away from the affected animal.

Seasonal Occurrence. The seasonal variation in the prevalence of some manges, has long been well known. The number of reported cases gradually rises during the advent of colder weather (October), and continues so doing until about February, when there is a gradual decline. In the summer months the disease is at its lowest. These remarks apply equally to the psoroptic and chorioptic forms, but sarcoptic mange of the horse does not appear to be quite so seasonal.

Sir Stewart Stockman says with regard to sheep scab (*Psoroptes communis ovis*) that there are several explanations of the decline that takes place during spring and summer. They are (a) shearing, (b) the sheep are not crowded together as in colder weather, (c) improvement in bodily conditions with advent of new grass, (d) the decline in movement (markets, etc.), and (e) summer dipping. He regards none of these as being fully satisfactory, and moreover, generally speaking, none of them strictly apply to town horses.

Mr. A. W. Anstruther, in the 1912 Report of the Proceedings under the Diseases of Animals Acts, says of parasitic mange "that considerably more than one half of the outbreaks reported occurred in the first three months of the year, and that during the summer months the prevalence of the disease declined, to rise again as winter approached. It is not a matter for surprise that this should be the case, as the conditions under which the horses are kept in the winter months are clearly calculated to bring the existence of mange to light."

He does not say what these conditions are, or whether they are different in town and country. The seasonal prevalence is very marked in towns, and the only different conditions, so far as I have been able to observe are, the presence of a long coat and lower atmospheric temperature.

One of the surest ways of preventing psoroptic mange is by clipping susceptible animals all over. When it is remembered that in summer animals may harbour the parasite without showing any symptoms, that the disease tends to disappear on its own with the advent of warm weather, and that clipping is a good preventive, it seems certain that an explanation of the winter prevalence—or the summer scarcity is to be found in the requirements of the parasites for (1) protection, (2) warmth, and (3) food, and not conditions of the hosts *per se*. Not only are cases less prevalent in summer, but those occurring are not so severely affected. Possibly then, there is not much distinction to be drawn between severity of symptoms and seasonal occurrence.

Parts Affected. The localisation of the mange mites upon their hosts is variously stated. Little or no dispute arises over the choriopt, its *habitat* is the legs. I have taken them from the chest wall and stifle; possibly in rarer cases it may go higher, and as this form is not included in the Parasitic Mange Order, the characters of the parasite here become important.

Roughly speaking, the psoropt inhabits all those parts that can be seen from a bird's-eye view, often starting along the spinal column.

My experience with the sarcopt has not been in accordance with the statements of most works on veterinary parasitology. Law says it is seen "most commonly about the head, roots of mane or tail, the withers or back"; Neumann, that it is "observed about the neck and shoulders"; Raillet, "on the withers"; Megnin, "on the back and withers"; Lemaire, "on the withers, back and sides." In all the cases which I have been able to examine, in the early stages, the disease has always been confined to the underparts of the body, such as the intermaxillary space, tracheal

region, and lower aspect of the chest and abdomen. From these seats it extends upwards. Taking into consideration the burrowing habits of the ovigerous female sarcopt, these are certainly the parts which one would have expected to have been attacked.

Diagnosis. Much can be gathered with regard to this from an inspection of the lesions and the parts affected. In summer, the psoropt can often be seen at the edge of the lesions; but the absolute diagnosis of the form of mange present must always remain a microscopic one. Let us remind ourselves that, provided disease is produced on a horse, an adult acarus whose four hind legs do not project beyond the body margin, is a sarcopt; one with suckers on the end of long pedicles on the four front legs is a psoropt, and one with suckers and apparently no pedicle is a choriopt. An undressed lesion should be sought out to obtain material for examination. The clinical features of the case will be some guide in taking material.

1. In summer, the psoropt can be looked for with the naked eye, or the hand lens applied to the edge of a scab or active lesion. Failing this, a little hair may be pulled, with its scab, from the edge of the lesion and warmed in a glass tube or petri dish, when the mites will be seen moving. If no parasites are found by these methods, a bunch of hairs with the scab should be taken and the scab snipped off with the scissors and allowed to drop into a petri dish containing a solution of caustic potash gr. xl. to ʒi. of water.

2. Hair from suspected chorioptic lesions must be treated in the same way. Nearly any part of the lesions will show them. It is immediately placed in caustic potash solution.

3. Material from the sarcopt lesion must be taken deeply, almost until the skin exudes lymph, and then placed under caustic potash solution in a petri dish.

After a period varying from a few minutes to several hours, the material can be examined in the dish under the lower power lens. The search can be made more accurate by placing portions of the moist material between two slides. The diagnosis lantern slides shown were taken in that way. By the above methods one is usually successful, but, of course, not always, and then the question arises, Does no acarus mean no mange? I feel sure that there are many cases of mange where it is almost impossible to find the acarus, especially in this so in a recent case on a thin skinned animal.

Principles of Treatment. Concerning these, one could say a great deal. No matter what aspect of treatment is being undertaken, it must be thorough. Sarcoptic mange is not the common form, and chorioptic can be treated similarly to psoroptic, so that my remarks will be directed to this form. These remarks are based on the records of over 1000 cases treated in different ways, and although you will most likely disagree strongly with what I am going to say, I feel sure that if you kept a similar record you would be forced to the same conclusion. Now the psoropt lives on the skin, and is not difficult to kill, so that if one observes the following principles in detail, treatment should be successful in a minimum amount of time. It is the time that animals are kept in the stable that is one of the teamowners' greatest grievances against the Parasitic Mange Order of 1911.

(a) Clipping. It is essential to clip the animal down to just below the stifles and elbows; there are many cases in which this is not done, either the owner has some peculiar idea as to the value of the winter coat, or he is afraid of spoiling the animal's spring coat. I know veterinary surgeons who do not consider clipping necessary, but if they were to analyse the results of their cases with regard to toxic symptoms, secondary pneumonia, and recurrence, they would be surprised. This mange is a disease of the winter and long coats, and the

value of removing the "cover" for the acarus is all important. I consider that the mane and tail should also be removed, because the parasite is in these places capable of obtaining a living without producing lesions of clinical importance for several weeks, or even months.

Besides reducing the death rate from toxic symptoms and pneumonia, a clipped animal uses less dressing. It is often wise in badly affected cases to use an old pair of clipping blades, on account of the liability of scurl to break the teeth. Clipping has other values; it reduces the activity of the parasite in winter, and so has a therapeutic value; it also shows the full extent of the disease. I cannot speak authoritatively with regard to the value of slow yet careful gas singeing immediately after clipping. In a few cases I found it apparently hastened a cure, whilst in others nothing appreciable could be noticed. If the weather and animal be warm, then it kills a great number of the causal parasite. If the treatment described hereafter be carefully carried out, I do not think singeing is necessary.

(b) Removal of abnormal epidermal products. This is the next most important step. It is simple or difficult according as to whether the case is a recent and untreated one, or an old standing and blistered skin. It is to be accomplished by the addition of about two to three ounces of soda, or acetic acid, to the gallon of hot water, and using this on the animal's body with soap. The most important point here is the choice of a suitable soap. Many soaps blister the horse's skin, and this is the one thing that must not happen if a cure is to be effected. Roughly speaking, any soap that can be used on a man's arms or face will be safe. After the animal has been lathered and soaked all over, the scrubbing brush will remove practically all the scales. Special attention will have to be paid to the mane and tail, and also to seeing that the animal is washed all over. There is no great objection to the addition of a little of one of the coal tar disinfectants to the water at this stage, although I think that it can just as well be saved for other purposes. After all the soap has been removed by warm water, the animal should be dried, rugged, and exercised, and bedded on straw. With proper grooming and exercise, many recently infected and untreated cases will recover without further treatment. I do not recommend stopping here, however, but only mention it as bearing out the chief aim of these remarks, viz., to show that in my experience treatment is more often than not, too energetic, and worse than the disease.

(c) Application of an anti-psoric dressing. On the day after washing, the animal has to be dressed with some agent which will kill the parasites that have survived their drenching in soap solution. The choice of an improper agent for this is by far the commonest cause of error in the treatment of this mange. I cannot do better than quote here a few remarks from Megnin, who says:—"Although parasiticides are numerous, a choice of them is difficult; many are dangerous, and it is not wise to permanently damage the animal's skin in order to rid it of parasites. Certainly one can cure sarcoptic mange with petrol and benzine, but causing at the same time an irritation of the skin which will persist for very many weeks, and at the same time producing an artificial affection with as many drawbacks from the point of utility of the animals as mange itself. This is the result of numerous experiments we have made. These show that one can cure mange by means of substances which kill the acarus, and at the same time allow the skin to retain all its softness and suppleness, and which allows the animal to be used immediately after its cure, which can be obtained in eight days. There are two substances which are acaricides par excellence, namely, sulphur and nicotine. These substances, mixed with soft greasy or oily excipients, constitute the best preparations against mange."

My experience with this form coincides exactly with Megnins of sarcoptic mange, with one exception, viz., that tobacco dust—which is used on account of its nicotine-containing properties, varies greatly in its compensation, and I have seen several deaths from its employment.

Oil and sulphur are then to compose our dressing. The sulphur demands no comment, but the choice of a suitable oil is most difficult, both from the therapeutic and pecuniary aspects. A suitable oil must not blister the skin, nor dry with a varnish-like layer, nor tend to turn rancid, nor prevent the normal functions of the skin taking place. In addition to these, it must be cheap. It is most difficult to get an oil to answer all these requirements, and one has to fall back upon the least harmful.

There are many bodies such as lard, lanoline, vaseline, or petrolatum (suet, horse fat, and goose grease are rarely used in veterinary pharmacy) and palm oil, which although occasionally employed can be discarded at once. They are dangerous when applied over large surfaces. Rape, linseed, and castor oils either cause dermatitis soon after application, or later on by forming a varnish-like film; olive oil is too dear, in addition to its tendency to become pasty in cold weather, to oxidise in air, and then go slowly rancid. The least dangerous oil is, I think, train oil. It is cheap. I have recently heard cotton oil spoken highly of. A peculiar feature about most oils is that for a period you will have no untoward damage to the skin, and then with the advent of a new supply of oil, comes marked skin corrugation in the treatment of your mange cases. This may be due to substances used in the refining process having settled to the bottom of the barrel. The proportion of sulphur to oil will vary 1/10 to 1/5 by weight. It is important that this dressing be supplied in an open vessel, such as a bucket, which can be stirred with a stick. Narrow necked opaque jars often contain several inches of sedimented dressing when broken. The animal should be covered at twice, the near side and then the off, at an interval of 24 hours. Here detail is essential; places commonly missed are the forehead, mane, tail, submaxillary space, breast, and inguinal region.

(d) Exercise and friction to the skin. The animal must now receive night and morning a good grooming with a duster, which can be wrung out in a suitable solution of some coal tar preparation. Exercise must be given twice a day. These last two items are as important as the others.

If a repetition of this course of the treatment is necessary, it can be undertaken on the 6th to 8th day, after which the animal should be able to resume work. The coat of a clipped and treated animal grows very quickly, and some time after returning to work, no harm can be done by again clipping and applying a dressing when it is at rest at the week end.

I know that mange cases are left in the stable and neglected, and that accounts for a great deal of the untoward sequelæ which we have to put up with. Many practitioners will recommend the addition to oil and sulphur of discutients, such as the alkaline carbonates or acetic acid; their work should, however, have been done before the dressing is applied. Oil of tar will be used by others. Some I know will laud tobacco refuse, but its varying composition is enough to my mind to bar its use. Lime and sulphur will have its advocates. Proprietary dips I have seen used extensively with terrible results. Admirable though many of them may be, they lend themselves to careless or over-anxious uses by horsekeepers or owners. If a small quantity is given out, half to be used in a bucket of warm water once a week, you may rest assured that the careful, or careless, man is most likely to use all the material in about three-quarters of a bucket of water, and apply it

for two or three days in succession—with disastrous results to the skin. I do not think that watery dressings on the horse have given such good results as one expected. The damaged skin, now more prone to irritation, wants some bland oil to replace the deficient natural oil and protect the abraded surfaces from the action of the air or acrid discharges.

What I want to insist is that our treatment must be mild. Perhaps it may be said that I am going too far in the mild direction. I am satisfied that I am not, but I am sure good will be done if some of the heroic treatments of to-day are replaced by milder measures.

There is much more that might have been said on the many other aspects of the diseases, but I fear that I have already taken up too much time.

After reading the paper Mr. Pillers exhibited the slides illustrated, and several others.

DISCUSSION.

Mr. BROOKE said that Mr. Pillers' paper had interested him beyond measure. When Mr. Pillers' read a paper at the last annual meeting, he gave them hints which many of them had found extremely useful, especially how to distinguish the three parasites with which they had principally to deal, and he had given them quite as practical a paper on this occasion. He would like to have the information contained in the paper preserved in some handy form. Mange was always cropping up in one direction or another, and the pictures which had been thrown upon the screen that afternoon had taught him a great deal. He and his friend Mr. Dawes had used the petri dish and had benefited very much from it. Mr. Pillers did not seem to have discovered the ideal oil for use in cases of mange, and he had excluded from his paper some that many of them were in the habit of using. They ought to use rugs with removable linings after clipping. To his (the speaker's mind, the dressing *par excellence* was sulphur, which could be coloured in cases where they did not want the client to know too much as to what they were doing. He had also used with some degree of success a mixture of three per cent creosole. Another good remedy was sulphur, oil of tar and linseed oil, but it was open to the objection that it dried in a varnishy fashion. He had searched the text books many a time for the very information Mr. Pillers had given them that afternoon, and he had either not found it at all, or it was expressed in nothing like so lucid a manner as the essayist had put it that day.

Mr. GRASBY said he had been an attentive student that afternoon, and had very much enjoyed the subject. He was glad to hear Mr. Pillers express the opinion that it was best to have the patient thoroughly washed before any application of the dressing. He thought the neglect of that precaution was probably the reason of many of their cases hanging on as long as they did. It was a good thing to have the patient well washed, but they should remember that some soaps blistered horses, which was a thing necessary to avoid. Soft water, plenty of bran, and a little energy on the part of the man was a good thing. He himself did not use much soap, but such as he did use was the best hard soap, like that used in the house. Mr. Pillers said the mane and tail were sometimes missed in washing, but he should have thought they would have been the very places at which a start would have been made, because they wanted to be clipped closely. It was new to him that they could rely on oil and sulphur only, because they had generally used turpentine and tar, which would enable it to stick to the skin so as to let the dressing do its work properly. He wondered whether in chronic cases Mr. Pillers thought it advisable to go on using such irritants as ammonia and turpentine, which were found necessary sometimes to get the scale off. The

harness that the patient had been wearing ought not to be overlooked. Speaking for himself he had the lining removed from the collar and saddle, and leather part boiled and afterwards treated with oil or something of that sort. He also insisted on a fresh lining being put in. For bedding, Mr. Pillers suggested straw, but in the Army Veterinary Department it was a regulation, in the case of mange, that the bedding should be removed, and the patient had to lie on the bare ground with a little sand thrown down perhaps. That was rather rough treatment, but it seemed to answer its purpose. He would sooner see the horse have a little sawdust than nothing at all.

Mr. GOOCH said he was struck with one matter which Mr. Pillers strongly emphasised, and that was the necessity for a preliminary treatment of the patient before the application of the dressing. That seemed to be the essayist's sheet anchor, and unless they carried out the clipping and washing, Mr. Pillers did not think the dressing would have a lasting effect. There had been some mention of the use of nicotine as a cure. Well, nicotine might be all right in the hands of an expert, but if left to the layman the results might be disastrous. He hoped Mr. Pillers would allow his paper to be printed *in extenso*; there was much in it of practical utility to the veterinary surgeon.

Mr. WARTNABY said the slides that had been shown to illustrate the paper were of more use than the paper itself, because without them the paper was of theoretical rather than practical use. He should like to ask Mr. Pillers if he could give them any real recipe for dealing with the scab parasite in sheep. There were many cases where he had inspected flocks of sheep and satisfied himself that the animals were suffering from scab, and he did not mind confessing that he had the greatest difficulty in finding the parasite. With regard to the dressing, he would be very glad if Mr. Pillers would tell them the proportion of nicotine he used. The dressing Mr. Wartnaby used himself, after having the animal carefully washed with warm water, soft soap, and a handful of washing powder, was train oil, sulphur, and tar thinned down with a little naphtha. If the patient was not better at the end of three days he applied it again, and let it stand another three days. Some years ago he took over the treatment of some pit ponies, about ten of which he found to be suffering from chronic mange. After some weeks treatment he thought he had cured them, but next autumn two of them broke out again. He adopted the same method of treatment and flattered himself for the second time that he had cured them, but they broke out again the following autumn—and so it went on for two or three years. He would like Mr. Pillers to say how he would account for that outbreak. He gathered that these parasites ought not to live more than a couple of months; how did they manage to exist the rest of a year?

Mr. FORSYTH said he had been adopting a milder treatment, simply train oil and sulphur, but he had a few cases, perhaps one in ten, where he had had to apply different dressing—a mild mercurial dressing. He had had cases recur months and months afterwards, and he did not quite understand them. He could mention cases where the patients had been kept strictly clean, and yet after being apparently cured they had to be treated again at recurring periods for sarcoptic mange. As to pit ponies he had never had anything out of the ordinary in recurrence of parasitic mange, but periodic eczema, especially in Russian ponies, was a very common thing. It cropped up twice a year, in the spring and in the autumn, as regularly as possible, but it was not contagious, and he had never found any parasites. A cooling application was generally better for them.

Mr. BROOKE: What is the situation of the trouble?

Mr. FORSYTH: Principally in the shoulders, but occasionally in other parts of the body, generally the parts

that come in contact with the harness. He thought the eczema was brought on by the sudden change of temperature in Russia, where they had frost and snow one day and sun the next. Mr. Pillers had given them his idea as to the parasite existing in the tail, but it was difficult to understand how it could go on for twelve months, and especially in a clean stable.

Mr. BAINBRIDGE said he could not understand the use of common soap and acetic soap, as one was alkaline and the other an acid.

Mr. PARKS said he used to have a certain amount of trouble in finding parasites, but when he tried keeping his scrapings warm, as for instance, putting them in an envelope and taking them home in his pocket, near his body, he had no trouble at all. He found exercise of great importance in treatment, although he recognised the difficulty of getting it done, especially in towns, where there was not always room enough. He believed, also, in disinfecting the stables and clothing, but he should have thought that boiling the leather part of the harness, mentioned by one speaker, would have spoilt it. In the country, they perhaps did not see so many cases, but if they made the man whitewash the place well when he has dressed the patient, and make him do it again and again, the veterinary surgeon could tell how much the animal was rubbing.

The HON. SEC. said that like other members who had spoken, he wished to thank Mr. Pillers for his more than interesting paper. When he was in correspondence with that gentleman on the subject he said, referring to the paper Mr. Pillers gave them on the last occasion, "It was a good paper, but we want something more practical this time." Certainly Mr. Pillers had carried out that injunction to the letter, and after all, veterinary surgeons in practice required a paper such as they had heard that afternoon, instead of listening to a lot of theory explained in scientific language, which they sometimes soon forgot. With regard to mange, he thought they had more difficulty with cases that had already been treated. When an animal had already been dressed with a strong dressing it was often very difficult to find the parasites. He had sometimes searched in vain, although he was quite certain all the time that it was a case of parasitic mange. Another difficulty they had to contend against was that the treatment ordered was not always carried out thoroughly. A veterinary surgeon sent a dressing to a client with instructions how to apply it, and it was frequently done in a slipshod manner. The consequence was that they did not get rid of the disease as soon as they might. He knew a man who went about treating mange very successfully, not because there was anything particular about his dressing, but because he was very thorough and very careful about his work. In towns the disease was very prevalent. It was difficult to get patients exercised, partly because the authorities objected, and partly because many owners had no room on their own premises for the exercise to take place.

Mr. EVERSHED described the paper as one of the most useful he had ever listened to; quite a small post-graduate course. As to the method of finding the parasite, when he was at Aldershot they took the scrapings and centrifuged them, the heavy parasites falling to the bottom of the tube. Did Mr. Pillers adopt any particular treatment for each different parasite, or was his treatment the same for all? He endorsed what a previous speaker said about the removal of all bedding in mange cases in the Army, and the result was always satisfactory.

Mr. BROOKE said he would like to ask another question that had occurred to him during the course of the discussion. Was there any means of enabling them to diagnose a case of mange from one of eczema. He had often found a difficulty himself in the matter. In the smaller animals, and in cats in particular, they were all

familiar with face mange. Was there any reason why it should be in the face almost exclusively, instead of wandering all over the body?

The PRESIDENT, in closing the discussion, gave some of his own experiences. He said he learnt a lesson once in a curious way. He had a case which kept recurring, although the stables were always kept scrupulously clean, and then it occurred to him to have the shafts of the carts cleaned. That was evidently the secret of the trouble, because they had no more of it afterwards. With regard to the treatment of leg mange, he found the old-fashioned remedy, oil of tar and black sulphur, answered very well. There was what was called the South African treatment, and the dressing, which certainly had proved very successful, was composed of the following ingredients: 4 ozs. of paraffin, 2 ozs. of lard oil, and soap solution (1 lb. to the gallon). It was an ideal dressing, cheap also, and made the skin as soft as a glove. As to putting rugs on horses that were clipped, it was not at all necessary. He had eight horses that were clipped every season which never had a rug on them, and they looked as well as anybody else's. Nicotine, he thought, was a dangerous thing to use, and he knew of cases where it had been used on sheep with fatal results. There was a firm in Glasgow that made it at a standard strength. In experienced hands, it was a good thing perhaps in its way, but he would advise them not to try to make their own, as they could never be sure what strength they had got. Some tobacco was different from others.

Mr. PILLERS, replying to the discussion, said the best way of thanking him for any trouble he had been put to in the preparation of the paper was to listen to him as attentively as they had done that afternoon. Their evident appreciation of what he had done was the only thanks he required.

Mr. Brooke advocated the use of rugs for clipped horses, but he (Mr. Pillers) thought that in the treatment of mange, rugs were objectionable. He had seen very few bad results, such as pneumonia, if the rugs were left off after clipping. Dispensing with rugs would probably meet with some opposition on the part of clients, and if they were afraid of offending a client they must act accordingly, but from the point of view of mange, rugs were a source of danger. Apart from the fact that they absorbed the dressing, if the rug became infected there was the danger of other portions of the horse catching the disease.

With regard to the particular oil to use, he thought train oil answered the purpose best. They might colour the sulphur, as one speaker had suggested, but black sulphur was used extensively, and that was not so easily detected. He did not want it to be understood with regard to the treatment that he said oil and sulphur alone were absolutely the thing. The addition of a little tar or turpentine might be a good thing, but his advice was "Don't overdo it."

As to the trouble which some members had mentioned in diagnosing mange, namely, where an animal showed no symptoms although literally swarming with mange lice, that was not at all uncommon. They might find any amount of parasites and no lesions. They might even have that particular animal among a lot of other animals, and none of the others catch it, whilst on the affected animal the disease may not spread at all. He did not think they could say it was not mange because it did not spread. He had been asked to explain why the parasites attacked certain parts of the body. They knew mange of the legs well enough, and there was a parasite that was found in the ear, but he did not know how to explain it apart from the theory of natural selection and the survival of the fittest. In the case of cats, their paws carried the parasite, and it got on the face in fighting. As for leg mange, it was what he might almost term the natural habitat of the

parasite, for there was plenty of coarse hair on the leg, and that was the place which the parasite sought out. Location was a curious circumstance, and he did not know that he could explain it in other terms.

The use of soft water and bran, as mentioned by Mr. Grasby, seemed a good idea. As to the use of bedding, he had seen animals with no bedding at all, but they often bruised themselves badly, and the remedy was thus sometimes worse than the disease. As to nicotine, he thought tobacco varied in its composition, and he had seen very bad results from it in the case of some horses. As the President had remarked, it was perhaps best to avoid it altogether. Mr. Wartnaby was not the only one by any means who had had the same difficulty in finding the scab parasite in sheep. It was often very difficult to find, and then one only succeeded after a prolonged search for lesions.

In all the different dressings that had been spoken of, the thing to remember was to set up as little irritation as possible. They had heard in the discussion about animals having the disease once or twice a year for two or three years. That was a feature of psoroptic mange; something happened, and the animal showed symptoms suddenly. The reason was that the coat became long, and the parasites wandered and so spread the disease. In dressing, some parasites got missed, and so the life history of the parasites went on all the time, although it was not observed.

Mr. Forsyth had mentioned what he called periodic eczema, but he (Mr. Pillers) was rather doubtful about it. He was inclined to think it was something parasitic. The want of thoroughness in the application of the dressing, as mentioned by Mr. Dawes, he had noticed himself, but of course they could not always be on the spot themselves, and so were obliged, more or less, to trust other people. In answer to Mr. Evershed's question about the treatment of the different parasites, he thought sarcoptic mange wanted treating a little more strongly.

VOTES OF THANKS.

On the motion of the Hon. Sec., seconded by the President, Mr. Pillers was very warmly thanked for his paper, and a promise extracted from him that he would allow it to be printed in *The Veterinary Record*.

A vote of thanks was also accorded to Mr. S. J. Marriott for making the local arrangements for the meeting, and providing the lantern and screen.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

Yew-Poisoning—Claim for Loss of a Horse.

At Kendal County Court before Judge Gawan Taylor and the Registrar, Mr. G. E. Cartmel, Mr. Ernest Bennett, carrier, Ambleside, claimed from the trustees of the late Miles Dixon, Grasmere (Messrs. W. Fuller and T. Wilson) the sum of £51, value of a horse which died from yew tree poisoning. Mr. Gatey appeared for plaintiff and Mr. W. Heelis for defendants.

Mr. Gatey said the claim was for the value of a horse belonging to plaintiff which whilst on the highway at Grasmere on 13th June ate a portion of yew tree growing upon property of defendants and died in consequence.

His Honour: Do you say the owner is liable if the yew tree branches don't project into the highway?

Mr. Gatey: Yes. There are a large number of cases between adjoining owners. It all depends in those cases on the projection; the man on whose land the tree grows is liable if it projects.

His Honour: And is there a distinction where the yew tree grows over an adjoining land and over the highway?

Mr. Gatey said that was a point he wanted to satisfy His Honour upon.

His Honour said there were no highway cases of yew branches, they were all cases of adjoining owners.

Mr. Gatey said that was so, but the present case had been foreshadowed by Lord Justice Collins in an imaginary case of a poisonous drug being exposed for sale and a child taking some. There was another case of a pitfall being made near a highway and a person falling in.

His Honour said there must be a limit to this doctrine. The horse in this case had evidently got its head over the wall and cropped a yew tree.

Mr. Gatey said this was a poisonous tree adjoining the highway interfering with the public enjoyment and therefore actionable if anything occurred. It was the instinct of the horse to eat anything green it might see.

Photographs were submitted, and Mr. Gatey said the wall projected at the place, and the yew tree was right in front of the horse's nose.

Mr. Gatey contended they had a right on the highway without their rights being interfered with by anything causing danger.

His Honour said, suppose they took a fishmonger's slab, it might have on it some fish poisonous to horses. It was a large doctrine.

Mr. Gatey quoted the case of Harold and another v. Watney in which a child had been injured by placing its foot on a fence bordering the highway when the jury found the fence to be defective and held that it was a nuisance and the owner liable.

His Honour said the horse might be a trespasser. It put its head into another person's garden and ate some yew. They must show how the owner of the horse could recover.

Mr. Gatey said "precisely." The mere fact of a horse being a trespasser did not prevent them having their remedy. There was the case of a man attacked in a field by a horse although he was a trespasser.

His Honour remarked in that case the owner had tacitly allowed people to traverse his field in which he kept a dangerous horse. The House of Lords had not gone so far as to say that though a man had been bitten by a horse or tossed by a bull, whilst trespassing, that the owner was liable.

Mr. Gatey said there was the case of dog spears where a man crossing over a garden was held to be entitled to damages. Although a trespasser a man was not entitled to have to meet any latent danger.

His Honour thought if a horse put its head over another man's land and ate yew the owner of the tree was not liable.

Mr. Gatey then proceeded to quote Hadley v. Taylor, the case of an unfenced hole, and Brown v. Midland Railway Company where a heap of stones by the roadside had caused the horse to shy. He submitted that both the plaintiff and the horse in the present case were legally on the highway, that the horse did not stop a long time, but simply for the purpose of loading and unloading, and there was no question of carelessness.

His Honour: This is a case likely to go further?

Mr. Gatey: Yes, your Honour.

The Judge said he would therefore take a full note and would now hear the evidence.

Richard Hudson, carter for Mr. Bennett, said on the 13th June he took a lurry load of goods to Grasmere, two horses harnessed, one in front of the other. On getting to Grasmere he stopped near Mr. Steane's shop and pulled his horses up about a foot from the side of the road. At the end of the footpath there was a wall projecting out into the road. There was a yew tree growing in the bend of the wall. He got on the lurry to move the cases to the back. They weighed about 1½ cwt. each, and witness had his back to the horse. Jack Gibson spoke to him, and in consequence witness got off the lurry and saw the leading horse with some yew in its mouth. He took out of its mouth all he saw.

The horse was then standing about a yard from the wall in the same position as he pulled it up. It took him about two minutes to deliver the cases at the back of the shop. He then went on the rest of his round and finished without noticing anything the matter, and got back to the stables about 6.30. He unharnessed the horse, took it out, put it in the stable and fed it. About ten minutes after he heard a noise and went to the stable. The horse had dropped down and was lying in the stall. He went to inform his employer, who sent for the veterinary surgeon. The horse died about five minutes later. It was a perfectly quiet horse.

Cross-examined: He had driven for Mr. Bennett about fourteen years, and had often called at the shop before, every week and sometimes more for ten years. He knew of the position of this yew tree, and that it was dangerous for animals to eat it. When he pulled up the horse was a yard from the wall.

His Honour said he could have pulled the horse up some distance away opposite the next shop.

Mr. Gatey said he would have had further to carry his cases, and having done this for ten years he scarcely anticipated such an occurrence.

Cross-examined? While on the lurry shifting the goods he had no control over the horse. He was not aware of anyone except Gibson drawing his attention to it. Dodgson did not.

John Gibson, grocer's assistant with his father in Grasmere, said on the 13th June he had business at the bank, which was in the same block of buildings as Mr. Steane's shop. On coming round the curve he saw the leading horse eating the yew tree. The driver was on the lurry with his back to the horse. He shoved the horse back into his chains. It was eating the yew. He called Hudson's attention to it as he knew yew was dangerous, and he said "All right," and got off to attend to it.

Richard Scott, M.R.C.V.S., said he had practised in Ambleside 13 or 14 years, and on 13th June was telephoned up, and was on the spot immediately. He went in the stable and found the horse lying in the stall, and it had practically just died as he went in. He advised a post-mortem, and made one next day and found distinct traces of yew tree poisoning, both undigested leaves and twigs in the stomach. The cause of death was an irritant narcotic poison called taxine, the active principle of the yew. It sets up gastritis generally, and causes great prostration. It was not unusually quick, as it depended upon the amount of food in the stomach. If there was a large amount of food it would neutralise the effect. This horse had a considerable amount of food in its stomach, which would account for the interval of five hours before death occurred.

In reply to His Honour as to whether yew poisoning did not set up peritonitis, witness said it caused inflammation of the stomach; it did not really get to the intestines. The horse was a sound one, six years old, and he valued it at 60 guineas.

Ernest Bennett, carrier, owner of the horse, testified to sending for the veterinary surgeon, and going to the stable where the horse was lying. He gave £51 for the horse on January 1st, 1912. The horse had improved since he bought it, and he could not replace it for that amount. The horse was not insured.

Septimus Dodgson, bootmaker and coach agent for Riggs, Ltd., and L. & N. W., said he occupied the garden where this tree grew, using it as a tea garden. On June 13th he saw Bennett's man and the two horses outside the chemist's shop. The front horse was reaching up into the tree, eating it. He called out to Hudson, "Look to your horse, it is eating yew." It had then got some in its mouth. He said, "Never mind t' girt —, it will not eat what'll hurt." Hudson did not get down, and Gibson then came. He had scarcely got the words out of his mouth when Gibson came over

the bridge and put the horse back. Gibson shouted from the bridge, and between him shouting and getting to the horse it went on eating. This distance would be eight or ten yards. Hudson answered Gibson something similarly as he did witness.

Cross-examined: He was tenant of the land on which the yew tree stood, and knew that such trees were poisonous to horses and cattle. Hudson was on the lorry busy moving cases about when he spoke to him.

In reply to the Judge, witness said Gibson spoke from the bridge immediately after him. It might be half a minute or a minute between Gibson speaking and moving the horse's head, Hudson being busy with boxes during the interval. The distance from where Gibson was to the horse's head would be about 15 or 20 yards. It would have been just as easy for Hudson to have jumped off and gone to the horse as witness. The horse would have had time to have got one mouthful before any of them could have got to it. He did not realise, but he had heard it spoken that yew was poisonous.

Mr. Heelis said this was all his evidence, and the court then adjourned for a short interval.

Upon resuming, the Judge said assuming there was negligence (though he did not endorse that proposition) on the part of defendants, there was evidence that Gibson and Dodgson cried out to the driver that the horse was eating yew, and the driver did nothing whilst Gibson traversed the distance of 20 yards to the horse's head. What evidence had he that before Gibson or Dodgson cried out the horse had taken enough yew to kill it? By the exercise of reasonable caution the driver could have avoided the consequences of defendant's negligence, assuming there was any.

The Judge and Mr. Gatey continued to argue the point as to whether the driver had exercised every reasonable care.

Mr. Gatey also held that they were entitled to have the free use of all parts of the highway without risk of coming to any harm.

The Judge replied that the first principle of common law was that defendants were not liable if plaintiff could have avoided the consequences.

Mr. Gatey mentioned that the driver had been going over that road for ten years, and had no reason for thinking such an accident would ever happen.

The Judge said the driver, on his own admission, knew of the danger of yew trees, but never took any care whilst Gibson was 20 yards away.

Mr. Gatey said he did not think they could take Dodgson's evidence as conclusive. He was standing a few yards away, and if he thought there was danger he could easily have stepped the length of the lorry.

His Honour: But he called out, "Look after your horse." The driver should have got there.

Mr. Gatey said it was impossible for anyone to foresee these little points.

His Honour admitted it was so, and said Mr. Gatey had argued with great moderation.

Mr. Scott was re-called, and said he found considerable traces of yew amongst the rest of the food, corn and hay, partly digested along with the food. It had to be partly digested to get the active principle out of the poison. It must have had quite a feed of it, as there was a lot of yew about the stomach.

In answer to the Judge, witness said a smaller quantity might have proved fatal. There was a large amount of food, which would help to neutralise the poison to a certain extent. If there had been two mouthfuls less, he did not suppose it would have made much difference. It was a typical case of yew poisoning.

The Judge repeated, "Why did not the driver pull the leader back, jump down, and pull every scrap out of its mouth?"

Mr. Gatey: Exactly what he did. Even if His

Honour held there was negligence on the part of the driver it did not disentitle the plaintiff to recover.

The Judge: Assuming negligence, was the defendant's negligence the cause of the loss?

Mr. Gatey: Were the defendants justified in putting on their land anything which required reasonable care to avoid?

The Judge: Was the loss caused by defendant's negligence, or was it caused by plaintiff's own negligence? The inclination in my mind is that it was due to contributory negligence on the part of plaintiff's man, unless you can satisfy me that the assumed negligence of defendants was the cause of the loss. There is no evidence that the horse had taken enough yew, before the attention of the driver was called, to kill it.

Mr. Gatey: If your Honour is against me on that point, I have no case. I came here to establish that the plaintiff had a perfect right to be on the road, to draw up his horse at this place, and to load and unload goods.

His Honour: But if the plaintiff had knowledge of the dangerous qualities of yew, he was guilty of contributory negligence in leaving his horse there.

Mr. Gatey: But here the defendants have four shops. Every article has to be brought by road, and horses and carts are standing there daily. Yet you allow a yew tree to stand. The defendants enjoy the rents of the shops, and we have to serve them. They put the poison right in front of the nose of our horse.

The Judge: The horse put its nose over the wall.

Mr. Gatey: Look at the danger of driving a herd of cattle past. The leading cattle could get several mouthfuls before being stopped.

His Honour: That is a very interesting point, but I am afraid I cannot decide it to-day.

Mr. Gatey: If you say there was negligence you are against me.

His Honour: I don't want to put it too high, or be too harsh. I think the man was guilty of want of care. He had a summons or a shout from the man at the bridge, and did nothing.

Mr. Gatey: If you are against me on the question of the carter being negligent, or not having done all he ought to have done, I cannot do anything more.

His Honour assumed the point had been established that by exercising reasonable care the carter could have avoided the consequences of his own action, and found judgment for defendants.—*The Lakes Herald*.

The Hunting Memorial Fund.

A meeting of the Sub-Committee of the above Fund will be held at the Royal College of Veterinary Surgeons, 10 Red Lion Square, W.C., at 7.30 p.m., on Friday, Dec. 12th. Chairman, Prof. James Macqueen.

Subscriptions Received up to 7 p.m., Dec. 3rd.

ANNUAL REPORT OF THE CIVIL VETERINARY DEPARTMENT PUNJAB.—By Lieut.-Col. J. Farmer, Chief Superintendent. [ABSTRACT.]

The following officers held the several appointments:

Chief Superintendent.—Maj. G. K. Walker,
Lieut.-Col. J. Farmer.
Superintendent, N. Punjab.—Mr. Woodley.
" *S. Punjab.*—Mr. Taylor.
" *Govt. Cattle Farm, Hissar.*—Lieut.-Col. J. Farmer, Mr. Branford.
Officers under training.—Mr. Meadows, Mr. W. A. Pool, Mr. W. Taylor.

The duties of the camel specialist were carried on by the Chief Superintendent for a short time when Mr. Leese was on leave.

The supervision of the Cattle Farm at Hissar has been placed upon the Chief Superintendent since Lieut.-Colonel Farmer took over charge from Major Walker.

Treatment of Disease.

During the year under report 28,125 deaths from contagious disease were reported against 25,455 last year. The increase is due to the large number of outbreaks, and also to the fact that a comparatively small number of cattle were protected from rinderpest by inoculations as fees for inoculations were charged. The people have been accustomed to have themselves and their children vaccinated and inoculated free; therefore they cannot understand why their cattle should not be treated accordingly. The Chief Superintendent, after a considerable amount of trouble, managed to get inoculations done in Jhang where the people are very much against it. A few zaildars, after his lecture, came forward to pay for 100 cattle to be inoculated in their zails. This will show the people the benefit of inoculation.

Deaths from equine contagious disease number 71, against 59 last year. The increase is accounted for by surra.

Glanders has again been prevalent on the Pathankot, Palampur and Dalhousie tonga lines. Very energetic measures have been taken to put a stop to it.

There are now two veterinary assistants, one for the Dalhousie line and one for the Palampur line. Should the disease still continue, two more veterinary assistants will be appointed to detect cases.

The Chief Superintendent considers it very necessary that all licensed ekka and tonga animals in all the districts in the Punjab should be examined and passed by veterinary assistants and some responsible officer before licences are issued.

Surra.—There were 25 deaths from surra as against 16 last year. Muzaffargarh district alone accounts for the increase.

Strangles as usual was prevalent. This disease shows itself during and after fairs. It is very difficult to prevent this. Inspections are made of all animals and diseased ones isolated, but it is quite possible for a case not to show any external symptoms at the time of entering the fair ground.

Tetanus, mange, and bursatee were also prevalent.

Rinderpest was reported from every district in the Punjab. The mortality was 12,924 against 9,317 last year. Although the year was not an unusually unhealthy one, the heavier mortality can be said to be due to the fact that more inoculations should have been performed, but as fees have now been withdrawn, better results will ensue.

Treatment with potass permanganas was carried out in the central circle. Out of the 159 animals so treated 130 recovered. More will be done when opportunities occur to prove the success of this treatment.

The Department has been explaining to the people

the absolute necessity for isolation and nursing. The Chief Superintendent had an opportunity of explaining to the different gatherings the results of bad feeding. It is only by dealing with the people in this way that they get to understand the elements of practical hygiene and so improve the conditions under which cattle are reared. The disease in a famine year is generally worse, as the animals are so debilitated that they are unable to withstand an attack of the disease, and there is no reserve of good fodder with which to feed sick animals during convalescence.

18335 inoculations were performed in 197 outbreaks which occurred in 19 districts; 3,651 uninoculated and 67 inoculated animals died in the course of the outbreaks. A few of the district boards have paid for inoculations which has been a great help to the department. Had it not been for them the mortality would have been heavier than is reported.

Foot-and-mouth disease.—This disease was reported from 23 districts, and 323 animals died against 684 last year.

The mortality from this disease is very small, and is chiefly caused by flies (*Sarcophagus liniata colis*). This fly is capable of laying at least 20 larvae in a minute on the sores in the interdigital space and mouth. The same fly causes a great deal of trouble in rinderpest.

Although the deaths from foot-and-mouth disease itself are very small, the deformities caused in the feet by it and maggot infection are very great, and this is chiefly the reason of so many bad feet in the country. It also affects the development of young stock.

Material from foot-and-mouth disease cases was sent to Bareilly for the benefit of the Royal Commission investigating the disease.

Haemorrhagic Septicæmia was reported from every district in the province. 8676 animals died against 10,894 in the previous year.

From the Chief Superintendent's personal experience it is ascertained that the disease remains confined to certain areas where water lies in shallow pools where land becomes inundated, and in places where canal water gets on to already infected land, which is not cultivated.

The following occurred on the Hissar Farm. There is a shallow tank which was supplied from the Western Jumna Canal. Haemorrhagic septicæmia occurred at all times of the year, and after careful investigation it was discovered that the herds affected with the disease grazed on the banks of this tank. The area was enclosed with a thorn fencing, and the disease in consequence stopped. About three weeks later, owing to a storm, the fencing became breached, and the animals got into the area and the disease broke out again. The breaches were repaired and the tank dried, and the grass and jungle on the ground all round cut and burnt. The intention was to have the whole place well ploughed up, as it is believed that if these places are so treated, the organism which lies under the soil, where there is still moisture, if exposed to the sun will be destroyed. The Chief Superintendent has been advising zaildars to have this done. At what depth the organism survives he is unable to say. In large infected tracts besides rivers he recommends that cattle be kept away until the ground becomes dry on the surface and the grass is fully ripe. To expect a grazier to prevent cattle going to these areas before they are dried, is a great deal. Until the people thoroughly understand the benefit of the system, vaccination will have to be done. This method will be carried out experimentally next year in as many places as possible. He thinks, from his experience, that it is not fly transmitted.

Preventive inoculation.—1043 animals have been inoculated with haemorrhagic septicæmia serum in 9 outbreaks, and 1332 were vaccinated in 27 villages in 6 districts.

Blackquarter.—The mortality from this disease is normal. Until inoculations are performed regularly, *i.e.* after animals are weaned, in infected areas the mortality will not decrease. At the Hissar Farm this is done, and the results have been good. Deaths do occur before weaning, but not so often as after weaning. The immunity lasts for six months after vaccination.

At Hissar certain jols (low-lying depressions where grass grows luxuriously and keeps green for a longer time) were cleared out and burnt one year; the result was good and fewer cases occurred.

Investigation of diseases.—Information was received by the Chief Superintendent that a disease called phutka amongst goats in Kangra and Kulu was devastating the flocks. The goats belong to a class of people called Gaddis. They graze their animals over very large areas. They march their sheep and goats at least five miles a day. After a great deal of difficult marching and visiting their encampments, cases of the disease were procured, and were sent to the College for investigation, as the Chief Superintendent's time was fully occupied in investigating the disease in the field. The disease is a contagious pneumonia, and owing to the goats being marched daily, it gives the animal very little chance of recovery. The necessity of isolation and giving rest to diseased goats has been fully explained, but it is a difficult matter to carry out, as Gaddis cannot stay more than a day at a place when on the march, owing to rules and regulations laid down. In this way ground becomes contaminated, and fresh flocks passing that way are affected. Before the Chief Superintendent's visit the Gaddis were so suspicious that they would not divulge where the disease was prevalent. This suspicion has now been overcome. A great number of goats die of inanition brought about by inability to graze on the hill sides, owing to their being crippled by diseased feet. The disease is caused by injuries in the cleft of the foot, followed by abscesses. Gradually the horn of the foot sloughs and the disease extends up the leg. The injuries, if attended in time, can be cured.

Specimens.—One hundred and sixty specimens were received and examined by the Chief Superintendent, and 85 and 269 by the Superintendents, North and South Punjab, respectively. Specimens of blood-sucking flies and ticks were collected and forwarded to Pusa. The Chief Superintendent hopes that in the future, veterinary assistants will know more about the flies and ticks in the province than they do at present. It is hoped that next year the areas showing the different species of flies will be mapped out.

Other Diseases.

During the year 9,948 villages were visited by the veterinary staff on tour, and 63,416 animals were treated.

2268 castrations were performed against 1059 last year. Although there is a marked increase, but yet it is insufficient. Cattle breeding will never improve until a large number of castrations are performed.

Veterinary Hospitals.

At the close of the year there were 113 hospitals in the province, at which 270,889 cases were treated, against 109 hospitals and 241,291 cases in past year. This is very satisfactory increase, and indicates the growing popularity of the institution.

At present there are 86 veterinary hospitals on approved plans. The Chief Superintendent is glad to say that after a little persuasion a new veterinary hospital is being built at Amritsar. He has to thank Mr. J. Addison for his kind help in the matter.

The only income is from fees which amount to Rs. 18,489, against Rs. 16,450 last year. This is a satisfactory increase. The Department is not a commercial one, and what should be remembered is the amount of

good done to the sick and lame animals, belonging to the poor, free of charge.

All cruelty cases arrested by the Inspector, R.S.P.C.A., on the Pathankot-Dalhousie line are treated at the veterinary hospitals. A great number were also seized and sent to hospitals by the Superintendents of the Department for treatment. This Department has done a great deal more during the year to alleviate the suffering of the dumb animals than the outside public can imagine.

The Simla veterinary hospital is doing good work, and is self-supporting. Veterinary Assistant Ghulam Hussain deserves great praise for his work. During the year the income was Rs. 5,644. After deducting all expenses, Rs. 3,250 were credited to the provincial revenues.

DISEASES OF ANIMALS ACTS, 1894 TO 1911.

Salaries of G.V.S. in S. Africa.

A correspondent in South Africa writes us that the sums shown in the note at p. 227, Oct. 4, are incorrect, at least so far as South Africa is concerned, and points out that in an advertisement in our issue of May 4, 1912, the salary offered is to commence at £350, and to rise to £500 by annual increments of £15.

REVIEW.

CLINICAL BACTERIOLOGY AND VACCINE THERAPY FOR VETERINARY SURGEONS. — By WILLIAM SCOTT, F.R.C.V.S. Pp. xvj. + 222. With 12 plates and 37 figures in the text. Price 7/6. net (Baillière, Tindall and Cox, 8, Henrietta Street, Covent Garden, London).

In one respect this book is a remarkable one. It is the work of a country practitioner who for some years has been carrying out the whole routine of vaccine therapy—including the preparation of autogenous vaccines—in his daily practice, and its aim seems to be to induce others to do likewise. Very few veterinary clinicians have yet attempted to work in this direction single-handed, and the book is interesting on that account.

For purposes of review, the work may roughly be divided into two sections. The first deals with laboratory apparatus and technique, the identification and cultivation of bacteria, the preparation of vaccines, and similar subjects. The only criticism that seems necessary here is that this section contains nothing new, and that the whole of its matter may be found treated in greater detail in so many other books that it seems a pity that it was allowed to occupy so much of this one. As it stands, it is necessarily condensed, and we doubt whether it would be found sufficient as a practical guide to those taking up the subject. On the other hand, its inclusion has led to the compression of the second and more original section of the work. This consists of a series of short articles upon different diseases in which vaccine therapy is, or may become, beneficial, and the list is a comprehensive one. Tuberculosis and its

secondary infections, distemper, strangles, pneumonia, bronchitis, tetanus, diarrhoea, and dysentery, pyæmic, and septicæmic arthritis, follicular mange, poll-evil, fistulæ of the withers and præsternum, endometritis, anthrax, and black-quarter may be mentioned as a few.

The author has had practical experience in treating most of these conditions with vaccines, and this summarised experience makes the real value of the book. Without entering into details, we may say at once that there is much in this section—especially with regard to dosage, and the combinations of vaccines and sera—that will be suggestive and helpful to practitioners interested in the subject.

In a future edition, we hope to see this section of the work extended, and at present the author may be thanked for helping to open up a new field to clinicians. There are evidences of hurried writing in the book, and there are portions which seem superfluous. But upon the whole it will be a real aid to any who desire to work along the same lines.

A JOURNAL OF ANIMAL PSYCHOLOGY.

We have received a prospectus, including some specimen pages and illustrations of a new German journal devoted to animal psychology. The title—*Tiersele Zeitschrift für Vergleichende Seelenkunde*—may be translated as—“Animal Mind. Journal for Comparative Psychology.” It is edited by Herr Karl Krall, of Elberfeld, a well-known student of the subject, and is issued by the publishing house of Emil Eisele, of Bonn. Four numbers, each of from 88 to 100 pages, will appear during a year, and the annual subscription will be 12 marks inland, and 14 marks if transmitted abroad.

The index and specimen pages before us include a good number of articles—many of them by doctors and professors—upon animal psychology, the protection and rights of animals, and similar subjects; and several of the articles treat of the “educated horses” of which so much has lately been heard in Germany. One feature of the work is a comprehensive bibliography of the subject; and the specimen illustrations are all good. To those who are interested in this very controversial subject and can deal with the German language, we should say the publication is well worth its price.

W. R. C.

“Post-Graduate” Dinner.

The members of the Post-graduate course entertained Sir John M'Fadyean and his staff to dinner at the Trocadero on the 26th inst. Mr. G. J. Harvey occupied the chair and proposed the health of the guests of the evening. The following were present:

Guests.—Sir John M'Fadyean, Messrs. Sheather, Knowles, Hayhurst, and Lander.

Members.—Capt. Collier, Capt. Rees-Mogg, Messrs. Dixon, Richardson, Poulton, Eadie, Penhale, Phadke, Gosling, Sheffield, Finch, Taylor, Shawcross, Grey, De Kock, Brookes, Fraser, Ward, Danbrey, Scott Moncrieff.

Sir Stewart Stockman, Mr. Cooksey, and Mr. Chamberlain, who sang some excellent songs, were also present as private guests.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Dec. 2.

REGULAR FORCES. ARMY VETERINARY CORPS.

Major A. H. Lane retires on retired pay. Dated Dec. 3.

Personal.

Mr. E. NETTLESHIP, F.R.C.S., of Longdown Hollow, Hindhead, Surrey, who died on Oct. 30, left estate sworn at £26,768 gross, and £23,225 net. After the death of his wife he left certain legacies to relations and friends, and also the following charitable legacies payable after the death of his wife:—£3,000 to St. Thomas's Hospital for the creation or augmentation of a fund for the endowment of lectureships in the medical school, and £1,000 to the Royal London Ophthalmic Hospital. He also left a share of his residuary estate to the same charities after the death of his wife as follows:—If the ultimate residue of his estate exceeds £9,000, then £2,000 to the medical school of St. Thomas's Hospital for the same purposes as the above-mentioned legacy to them, and £1,000 to the Royal London Ophthalmic Hospital. If the ultimate residue is less than £9,000 but over £6,000 the share of the hospitals is to be reduced accordingly; but if it is under £6,000 the whole is given to relations of the testator.

OBITUARY

JOHN S. DRABBLE, M.R.C.V.S., Halifax, Yorks.
Graduated, New, Edin: May, 1900.

Mr. Drabble died at Halifax on December 1st, from influenza, with acute lobar pneumonia. Aged 37 years.

THOMAS FOWLER HUTCHINSON, M.R.C.V.S., Leyland, Preston.
Lond: April, 1865.

Death occurred on Nov. 27th from arterio sclerosis, terminating in cerebral hæmorrhage, at the age of 67 years.

JAMES ROBT. WHITTLE, v.s., Westgate-on-Sea, died on November 27th from rupture of aortic aneurism. Aged 72 years.

CANKER.

Sir,

I have bitten off more than I can chew. I thought that, on account of my note on the above disease, I might be called upon in the course of a few weeks to answer a stray correspondent as to how I treated my cases. Monday morning's post brought me thirty letters on the subject, and they are still arriving. The postman must think that I have started a matrimonial agency.

As I cannot possibly write to each of these numerous correspondents, I am having a leaflet printed, giving my views and mode of dressing, which I hope will be accepted under the circumstances as an answer. Many of the letters are most interesting, and I could not help thinking that it would be to the advantage of the profession if some of my correspondents would become occasional correspondents of yours. Two things are apparent. Canker is of much more frequent occurrence than most of us thought. None of the methods of treatment usually practised are effective in severe cases—that recommended by Mr. Malcolm is spoken of favourably in a few letters, but condemned in many others. The fantastic method of bits of rolled tow gets no support, and every correspondent who has tried arsenic internally found it useless.

Nitrate of lead, spirit and formalin, carbolic acid, dry dressings, iodoform, etc., all have for the most part proved unsatisfactory. In the course of a couple of months I hope to be able to state how the method that I have found successful is viewed by others.—Yours faithfully,

W. R. DAVIS.

ARSENIC IN TREATMENT OF CANKER.

Sir,

I notice that Capt. Hilliard, A.V.C., reports a case of canker which made a complete recovery under the treatment of arsenic. I also had a case in an Artillery horse at Meerut three or four years ago which made a complete recovery from canker under the treatment of arsenic, but after several months the disease broke out again and the horse had to be destroyed. I hope Capt. Hilliard will be more fortunate.—Yours truly,

GRAHAM REES-MOGG.

November 26.

“PROFESSIONAL”?

Sir,

I hope that you can find room for the enclosed cutting from *The Farmer and Stockbreeder* of December 1st, 1913. I should like to ask the members of the profession if they think they have reason to be proud of “Vet.” as a fellow member.—Yours, etc.,

COUNTRY PRACTITIONER.

Delayed Puberty (B).—Yes, there is a special method of operating on rigs, which you should learn as a castrator, or you are at a disadvantage compared with some others. There is an American book called “Animal Castration,” by Liantard, price 10s. 6d., published by Baillière and Co., Henrietta Street, W.C., which both describes and illustrates it. The odd testicle can often be got without this diving into the abdominal cavity, if the animal is chloroformed and the operator gets someone else to put his arm up the rectum and press towards the scrotum, while he works his hand from a backward position and brings along the testicle. You will better understand what is meant by referring to pigs, whose testicles can either be pushed up close to the anus or down some distance towards the navel, and can be taken out in either situation. You will no doubt have found one testicle in all sorts of odd places in the flank. Before you decide that the missing organ is inside, a full exploration should be made. Complete insensibility under chloroform relaxes the cremaster muscle, which may alone be the cause of the testicle being held up.

—VET

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1327.

DECEMBER 13, 1913.

VOL. XXVI.

PATHOLOGICAL OPPORTUNITIES.

English veterinary surgeons are notoriously averse to recording their experiences; and in one direction they are especially so. A good number of them are now engaged in meat inspection, but far fewer report their results here than abroad. On the Continent, reports from the abattoir are very common—sometimes in the form of a series of observations upon one condition, sometimes as reports of single cases of interest. Published with scientific detail in the journals, such reports are far more valuable than the bare official statistics of an abattoir; and they have helped the advance of pathology considerably. But very few veterinary sanitarians in this country follow the example of the Continental ones; and the fact that one or two have produced really valuable reports only makes the reticence of the majority the more regrettable. Some of our members are inspecting, and presumably studying, diseased meat and organs every day, and never think of recording these observations.

There has never been a time when our profession held so many special branches of work, each full of opportunities to the men engaged in it, as to-day. Preventive medicine holds many such opportunities apart from meat inspection, and the two diseases most recently scheduled are examples. We have previously called attention to the scientific possibilities of work under the Tuberculosis Order, and we all know that there is still a great deal to be learned regarding equine mange. Without dwelling upon such other special branches as tropical medicine, and our now highly developed Army Veterinary Service, we turn to private practice. The general practitioner's life holds as many opportunities to observe and report as any, though it is often difficult to utilise them. Some of the commonest conditions of everyday practice are precisely those which most require further study. Canine distemper, equine respiratory troubles, the bovine mammites, some forms of arthritis, and many forms of skin disease in all animals, are only a few examples. Every man who is making a living by veterinary work, whatever its nature, has many opportunities of independent observation which would enable him to contribute a little to our common knowledge.

WOMEN AND PRACTICE OF LAW.

From a report which appears elsewhere in our pages it will be seen that the Master of the Rolls, Lord Justice Swinfen Eady, and Lord Justice Phillimore, composing a Court of Appeal, have decided unanimously that women are disqualified from becoming attorneys or solicitors. The grounds of the decision were, briefly, that the common law of England is to a great extent based on long-continued usage; that up to the present time no woman has ever been admitted, and until recently none has ever applied to be admitted, to the profession of attorney or solicitor; and that, therefore, women are barred from the profession by the common law until the Legislature expressly confers the right upon them.

A RARE SKIN LESION OF THE HORSE SOMEWHAT RESEMBLING DERMATITIS ERYSIPELATOSA.

By W. G. BERRY, M.R.C.V.S.,
A. W. NOEL PILLERS, F.R.C.V.S.

The three accompanying photographs show a peculiar skin affection met with by one of us (W. G. B.) recently. The first picture is of the animal when the disease was at its height; another, an enlarged view of the lesions behind the shoulder and below the withers; and the third, the animal after the disease had completely disappeared for some time—about four months after the first photo was taken.

The subject was a brown cart gelding about 11 years old.

On June 2nd, the animal had a severe febrile attack which developed into double pneumonia. The case ran a critical course, but ended in gradual recovery. He was moved from the sick box into his own stall, where he remained for eight or ten days in order to be exercised, preparatory to resuming town work. The action of bowels seemed to be slow, and there was slight constipation, a dose of linseed oil (half a pint) was therefore given on June 21st. During the night of June 23rd, he was attacked by this peculiar skin rash. There had been no premonitory symptoms whatever. On examination next morning, there was slight fever, the temperature being 102.2° F.

There was marked swelling on the hind quarters, which were inflamed and sore. The inside of the thighs, just below the perineum were moist and steaming. The body was scattered with a great number of large, painful blotches as shown in the first picture. Numerous small, elevated areas were present on the lips and face. For about a week fresh areas become affected, the hair first became erect, then there was an accumulation under the skin of the diseased area. The size of the lesions varied from that of a shilling up to the palm of one's hand. In a few days the elevation of the skin became hard and dry, and crusts could be removed by the hand easily. Underneath the scabs or crusts was a slate-coloured pus-like fluid. Swelling of the dependent parts was marked, especially along the breast and abdomen. This gradually became absorbed. During the second and third weeks of illness the pulse became very irregular, but later became steadier.

Diagnosis.—The condition was never absolutely diagnosed; the food remained the same as other animals were getting. Examination of the lesions for acari and ringworm fungi was negative (A.W.N.P.)

Several members of the profession saw the animal and expressed different "guesses" at what it might be. It appears to resemble most closely the *Dermatitis erysipelatos* mentioned on p. 877 of Huttyra and Marek "Special Pathology," vol. 2.

Treatment.—The food given was light, such as hay, oats, and grass, when this is obtainable. Internal medicants consisted of iron sulphate and vegetable tonics in powder form. Several agents were tried on the skin to allay the irritation or soften the crusts, but not one of them seemed to have any beneficial effects. Eventually, all the dead material was removed by careful rubbing with emollients, and as no fresh lesions appeared, and the animal was greatly improved, he was turned out to grass on August 14th, well on the road to recovery.

On October 25th he was brought up from grass apparently in good health and clear of any abnormality of the skin, as he is shown in the third photo; the winter coat gives the animal a rough appearance.

The case appeared to us worthy of record, especially as we had obtained good photos.

A PUZZLE IN LAMENESS.

The case of lameness reported by Mr. Howard in your issue of the 5th inst., is unusual, interesting, and probably impossible to diagnose definitely.

The report states that the horse is perfectly sound in action until the pressure of the saddle or the weight of a man is placed on its back, and then it walks very lame, trots slightly lame, and gallops sound. From this it may be inferred that it is not the sternum that is affected, as the horse goes lame when ridden bare-backed, and consequently there is no pressure from the saddle girths. Again it may be concluded that it is not the weight of the man on the horse's legs, as the mere pressure of the saddle produces lameness. Therefore, the probable location of the exciting cause of the lameness exists within the limited portion of the horse's back which a bare-backed rider covers when on the horse.

Mr. Howard states that on manipulating these parts he did not discover any tenderness. I suggest that the pressure he used was not as great as that of the saddle, and certainly not as great as the weight of the man who rode the horse, or perhaps he omitted to examine the exact parts affected.

If the foregoing reasons and conclusions be taken as accurate, the fact that the horse was perfectly sound in action except when saddled or ridden, and then it became very lame when walked, but only slightly lame when jogged and went sound when galloped, might be accounted for as follows: If the horse were high-spirited or hot tempered—as under these circumstances the pain caused by the pressure on the back probably would be aggravated by the more rapid motion; thus the horse might yield to the pain caused by walking, but become so exasperated with the pain intensified by the rapid

motion as to be goaded to disregard the pain, and consequently to go sound.

Some years ago I had a case that this one reminds me of. The history of the case, as given to me, is as follows:

A valuable horse, when being hunted, was jumped through a thorn hedge. When brought home it was very lame, and several large thorns were removed from above its knees; one of the knees became much swollen, and the horse remained lame on that leg for a considerable time. The groom thought a thorn had remained in the leg; however, as the horse did not yield to pressure on any part of the leg he was put to grass for the summer, and when brought into the stable apparently was alright, and was again prepared for hunting. He was hunted for the greater part of the season, and went in his previous good form, but at the end of the season became restless when saddled and walked in a fumbling manner, but still hunted, although he was not found so pleasant to ride as before.

The owner consulted me about the case before putting the horse to grass; I did not see the horse, but as the owner said he was sure there was something wrong with the horse's back I advised him to put a strong blister on it; this he did, and a few weeks afterwards wrote to me saying that a nasty warble had formed on the horse's back, and asked me to come and see it.

On my examining the so-called warble I found in its centre a small orifice with a slight thin, dark-coloured, ill-smelling fluid coming from it. I cast the horse, dilated the orifice, and on probing found a hard object. I at once made a free incision and removed a thorn fully 1½ inches long; it was not covered with fibrous matter, and seemed quite the same as if it were only embedded in the back for a short time, whereas the probability is that it gained admission at the knee and travelled through the tissues to the back.

This case is not so mysterious as my friend Mr. Howard's, but suggests a possible solution of the puzzling element in the interesting case which he relates.

JAS. McKENNY.

VACCINE THERAPY IN PNEUMONIA.

With the approach of winter the practitioner may have many opportunities of studying the relative value of vaccines in pulmonary cases. A few observations now on this important subject may not be out of season. At the outset one must confess in studying the subject of the bacteriology of pneumonia as seen in the lower animals, a somewhat unsettled condition still exists, and from the vaccine therapist's point of view, this is to him a great misfortune, and a severe handicap to his endeavours when prophylactic and curative measures by vaccine are adopted.

Whether the case is an isolated one, and developing as a primary pneumonia, or whether there

be many, and appearing as sequels to such conditions as influenza, the bacterial invasion is usually a mixed one.

The complicated nature of the infection increases the therapeutic difficulties when it comes to making a so-called autogenous vaccine, but as difficulties were made to be overcome, these should not damp his ardour; on the contrary, they should stimulate him to increased effort. On the other hand we know the limitations of drugs in such cases, for after attending to the patient's comfort, placing him in hygienic surroundings, maintaining his strength with nutrients, administering bowel, kidney and cutaneous eliminators to get rid of ever accumulating toxins, we fall back upon the *vis medicatrix nature*, and not a single thing we can prescribe under this régime brings us into fighting line with the invading bacteria, except vaccine therapy.

This brings me to the interesting consideration, How do vaccines act in pneumonia? To understand the *modus operandi* with reasonable satisfaction one must become conversant with the pathological changes taking place in the lung parenchyma. The bacteria capable of producing pneumonia are many, and that several are saprophytes under normal conditions, may be taken for granted. The protective agents of the animal body are reduced in efficiency, and the bacteria present in the respiratory tract gain a footing; their growth is rapid, and the destruction of many of their number is equally rapid. In the former condition exotoxins (depending upon the kind of bacteria) are liberated, and in the latter endotoxins.

The irritation set up by these bacteria and their products causes pronounced capillary congestion. The pulmonary vessels are gorged with blood extremely rich in leucocytes, but now deficient in antibodies. As a result of traumatic tension, serous effusion takes place in the lung parenchyma which transplants the air in the vesicles. Solidification now takes place through coagulation of the fibrin, and entangled in the meshes of which are red and white blood corpuscles, cast off epithelial cells, and dead and living bacteria. Microscopically this condition is known as red hepatization. At this stage the circulation is much interfered with, the red corpuscles now lose their hæmoglobin, an increased number of leucocytes invade the lung tissue, with a consequent diminution of their number in the free circulation. Grey hepatization has now set in, and is the first step towards resolution.

An animal suffering from pneumonia clearly indicates that the phagocytes and immune bodies are deficient. There may be other forces existing to complete the immune rôle, but of these two we are certain.

We know of no reliable agent capable of stimulating phagocytosis, but we do know vaccines stimulate animal tissues in the production of immune bodies. It must be patent, however, that to obtain the maximum benefit from vaccine therapy, the vaccine should be given in the early stages of the

disease, in which case the course of the disease will be shortened. When consolidation has set in, the hepatized area is largely cut off from the free circulation; the bacteria are encased, so to speak, in the fibrinous meshes in the alveoli, and the fluids which bathe these areas have already had extracted from them any anti-bacterial powers they may have possessed. In this condition the blood may, in itself, be very rich in anti-bodies and yet remain—owing to the above condition—bacterially passive.

I do not suggest that the practitioner should withhold his vaccines when hepatization has set in. On the contrary, they should be administered at whatever stage the patient is found, for as soon as cellular degeneration and resolution set in the immune bodies can reach the isolated areas, and restoration will be all the more rapid when stimulation by vaccine has taken place. It is obvious that in an acute disease such as pneumonia one cannot get a dose of vaccine into the patient too early. It is, therefore, good practice to inject a stock vaccine at the outset, preparatory to the making of an autogenous vaccine.

In those cases where the "crisis" is delayed, a full administration of vaccine by elaborating the required anti-bodies, hastens the process.

The vaccine therapist in pneumonia has two pressing objects in view, *i.e.* (1) the annihilation of the invading bacteria. This we have seen is brought about by stimulating the tissues to antibody productivity, and so increasing the opsonins, agglutinins, bactericidins, bacteriolysins in the circulating fluids; and (2) the neutralization of toxins circulating in the blood.

Vaccines have been found to be only slightly anti-toxic, so it is probable that in a typical case of toxæmia, such a large dose of vaccine would require to be given before any pronounced anti-toxic effect was produced that nature would be unable to assimilate such a large dose, so to speak; the negative phase would be so pronounced, and consequent depression so great, that dissolution would be liable to follow. Theoretically speaking, an antitoxic serum is here indicated, and I have had to all appearances good results by giving a polyvalent anti-streptococcal serum where streptococci are much in evidence.

Unfortunately anti-toxic sera in these cases have considerable limitations, for it appears such sera possess no curative powers unless the serum derives its immune qualities, not only from the same bacteria it is called upon to fight against, but also the same strain, and as some bacteria have many strains, failure of a certain serum to be anti-toxic is easily accounted for. It is, therefore, imperative that the anti-sera must be polyvalent.

Considerable progress has recently been made in human medicine by the administration of *sensitized vaccines*, and I venture to think these will give us more powerful anti-bacterial and anti-toxic remedies than ordinary vaccines.

When a dose of vaccine is injected into an animal his opsonic index falls, presumably due to the gathering up of the free opsonin circulating in the

body fluids. In diverting the opsonins from the lungs, the focal lesions are aggravated, the bacteria now have more their own way, more toxins are thrown into the blood stream, the respiratory and cardiac centres are being actively poisoned as well as the heart muscle, consequently the temperature rises, the respiration is more rapid, and the heart's action is laboured. These phenomena are only temporary, varying from four to twelve hours. This is known as the *negative phase*. The opsonic index now begins to rise, the focal conditions improve owing to the bacteria in the lung centres being

invaded by this first supply of antibodies, less toxins are formed, and a general improvement has set in. This may be maintained for one, two, three or more days, and is known as the *positive phase*. After which a high plateau is reached, remaining stationary for two or three more days, when the full effect of the vaccine will have passed off. At this stage a second injection should be given, and a careful note of the symptoms again made.

WM. SCOTT, F.R.C.V.S., F.R.M.S.

Bridgwater.

A MONSTROSITY.

Two fore feet and a head were presented. The feet were secured, and although there was plenty of strength it was impossible to get the feet more than eight inches from the vulva. I felt the case hopeless, and accordingly I shot the cow. I did not see the specimen on post-mortem, but through the courtesy of a brother practitioner I obtained the accompanying photographs.

I might add that it can be readily seen that an effort had been made to dismember the fœtus, but nothing was more impossible.

Two heads, two necks, two thoraces, four fore legs, one rump, two tails, and two hind legs—a useful combination.

W. W.

ABSTRACTS FROM FOREIGN JOURNALS

PERFORATING ABDOMINAL WOUND WITH SUPERFICIAL INJURY OF THE INTESTINE IN A HORSE.

Ludwig Gruber records the case of a horse which was staked in jumping a fence, causing a wound which penetrated the abdomen in the right flank, and allowed the intestines to protrude. Gruber found the animal in a very agitated condition. He first pushed back the protruding intestine, washed the wound with creolin solution, and then covered the whole with wadding, over which he placed two superposed and tightly drawn roller bandages. The horse was then carefully thrown for a more accurate examination.

This revealed a lacerated wound running in the direction of the external oblique muscle. The portion where skin abdominal muscles and peritoneum were all penetrated, through which the intestines appeared, was about 2 2-5th to 2 4-5th inches long. From the end of the completely ruptured portion

for about another 3 3-5th to 4 inches towards the ribs the abdominal muscles and peritoneum only were lacerated under the skin. Probably the stake had first been driven forwards under the skin by movements of the horse, and while being disengaged had then been thrust inwards and backwards through the muscles and peritoneum.

Gruber exposed the whole wound by slitting up the skin, and, after careful cleansing, pressed back the intestine with a towel dipped in an 0.5 solution of creolin. At one place he found a superficial laceration of the intestine about 4-5th inch long, reaching as far as the muscularis. This he cleansed with creolin solution and painted with Lugol's solution. The edges of the wound were trimmed, and the abdominal muscles united with very deeply applied catgut sutures, Lugol's solution being then applied to both the stitches and the united wound edges. The skin was similarly sutured with silk. The whole wound and its surroundings were then painted with tincture of iodine and sprinkled with iodoform powder, a thick layer of wadding and the roller bandages were again

applied, and the horse was cautiously allowed to rise.

At first, Gruber directed the after-treatment with the view of averting peritonitis. He gave ol. ricini, used clysters of a very weak creolin solution, and strictly limited the diet, giving only a little milk now and then. Externally he applied cloths wetted with alcohol to the abdomen, screening them from the atmosphere with a superposed bandage, and changing them at intervals of from six to ten hours.

The temperature, which was 105.6 F. the day after the operation, had fallen to 101.6 F. on the fifth day. The general condition was then good, and all fear of peritonitis seemed to be over, so that Gruber discontinued the alcohol bandages, and went on treating the wound with dry dressings. On the sixth day he removed the sutures, retaining the roller bandages as a precaution. Recovery was rapid and uneventful, and was complete after about three weeks.

Nine months later the horse was still at work and doing good service. The strain of work had not induced a rupture of the abdominal wall, which had been feared.

Gruber remarks that he considers dry dressings (such as those of iodoform with which he treated the case from the first) are to be preferred to the free use of watery disinfectant solutions. His experience is that dry dressings cause the healing process to be more rapid and more certain than ointments.—*Munchener Tier. Woch.*

PECULIAR POLYCYSTIC LESIONS OF A BOVINE LIVER.

Echinococcic cysts are well known to be extremely common in the bovine liver. Several authors have also recorded serous hepatic cysts in the calf, which are considered to be congenital. Squadrini has also a case of polycystic hepatic adenoma, and Lisi found cysts in a cow's liver, which resembled those of echinococcosis, but contained eggs of distomata. L. Carhenez now reports a case which he observed in the abattoir, and which differs from all the foregoing.

The bovine liver in question weighed about 88lb., and its surface was very lumpy. Upon the surface, and within the interior of the organ, were a considerable number of cysts, varying from the size of a pin's head to that of an infant's head. All the cysts were monolocular, the majority had a whitish translucent wall, and at first sight they suggested a case of echinococcosis. But, when incised, they were found to contain a liquid which was sometimes whitish, sometimes reddish, or even dark brown, and this liquid, when centrifuged, showed no formed elements. No vestige of a parasite could be discovered, and the author concluded that the lesions were non-parasitic. He then carried out a histological examination of the tissues in the neighbourhood of both small and large cysts, and of other portions of the liver.

The histological results are reported in some detail, and are here summarised. All the cysts

were lined by a single row of cells analogous to those lining the bile-ducts, and the author infers that the cysts had originated in bile-ducts. The remainder of the liver showed a considerable amount of cirrhosis. The cirrhosis had certainly had its starting point in the portal canals, where it surrounded both the vessels and bile-ducts with concentric layers of connective tissue. From the portal canals the process had extended into the rest of the liver, sending strands of connective tissue between the lobules. The cirrhotic lesions around the vessels had affected the circulation of the liver, causing the formation of local areas of congestion; and the hepatic cells in some lobules, compressed by the distension of the capillaries, had degenerated or completely disappeared. In the latter case the tissue, under a low power, had the aspect of adipose tissue: and this was especially marked in some of the lobules underlying Glisson's capsule. Glisson's capsule itself shared in the cirrhotic process: and some strands of connective tissue from it had fused with those proceeding from the portal canals.

The lesions were clearly old ones, and the author found it impossible to demonstrate their cause. He says nothing of the condition of any of the other organs.—*L'Hygiene de la Viande et du Lait*

THE INFLUENCE OF AGE UPON THE ORIGIN OF CARCINOMATA.

Dr. Teilhaber, of Munich, recently delivered an address upon this subject in Vienna. His view is that the fewer the cells that are possessed by connective tissue, the more easily does epithelium enter into it. Young connective tissue is very rich in cells; on the other hand, the connective tissue of old people is poorer in cells.

The disposition of old persons to carcinoma is explained by this circumstance. A second factor is the poor blood supply of the tissues of old people, and a third is the increasing atrophy of the blood-forming organs in age.

But, according to Teilhaber's view, these factors only render the irresistible growth of epithelium possible when the connective tissue of the part concerned has for a considerable time been impaired by cicatrization, chronic inflammation, or other causes.—(*Münchener Tier. Woch.*)

LAPAROTOMY FOR TORSION OF THE UTERUS.

Knitl, of Neumarkt, very briefly reports a successful case of this operation. A cow was affected with torsion of the uterus, which rolling of the animal failed to rectify. Laparotomy was performed, and enabled the turning of the uterus to be effected within the abdominal cavity, and parturition followed. The membranes came away four days later. Healing of the abdominal wound and retraction of the uterus took place promptly. Knitl gives no details of the exact procedure followed in the operation.—*Munchener Tier. Woch.*

W. R. C.

ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

A general meeting was held on Friday, Nov. 28, at 10 Red Lion Square, London, when there were present: Messrs. David Wyllie, President; J. C. Coleman, P. J. Simpson, R. C. Tennant, J. S. Hurndall, S. H. Slocock, Geo. Upton, Capt. O'Rorke, and the Hon. Sec. and Treasurer, Mr. G. P. Male. Visitors: Messrs. Ivan R. R. Coleman and J. W. Hopkin.

THE LATE MR. WM. HUNTING.

The PRESIDENT said that before they began the business he would like to refer, for the whole of the Association, to Mr. William Hunting's death. He was an honorary member of their Society, and was always very enthusiastic, attending their meetings and doing all he could to help them in every way. They all knew his many good qualities—his geniality, his willingness to help them and the profession generally. He thought it would be becoming to the Association to send a letter of sympathy and condolence to the family, expressing their feeling of the loss they had sustained.

The HON. SEC. read a letter, dated Nov. 23rd, which he had received from Mr. G. E. King, of Abingdon, in which that gentleman said: "I am afraid I shall not be able to attend the R.C.V.M.A. meeting on Friday next. I am making fair progress, but not nearly so much as I could wish. . . . I should like you to bring forward in my name at the meeting, if you will, a resolution recognising the services that Mr. Hunting has rendered our Society, the loss we and the whole of the profession have sustained by his death, and move that a message of sympathy be sent to Miss Hunting. Mr. Hunting was a very old friend of mine. I think I have known him some 28 years, and I had the greatest admiration for his professional abilities and for his personal character. He was a loyal friend and a generous opponent, and was always ready to give his advice and support to any object for the advancement of the profession. I should also like to suggest that a sum to be decided by the meeting, if it approves of the idea, be subscribed from the funds of the Association towards the testimonial being raised to perpetuate William Hunting's memory."

The HON. SEC. seconded the President's proposition, and the same was carried in silence, all standing.

The HON. SEC. said he was not aware that Mr. Hunting was dead until he happened to see a note of it in a daily paper, and he immediately wrote to Miss Hunting saying the Association would like to be represented at the interment, and expressing their deep grief and sympathy. There was no time for the Association to be officially represented, but Mr. Slocock very kindly attended for them. They were therefore also unfortunately unable to send a wreath, as they would have liked to have done.

Minutes.—It was agreed, on the motion of Mr. J. C. Coleman, seconded by Mr. Simpson, that the minutes of the last meeting be taken as read.

Apologies for inability to attend were announced from Messrs. W. Shipley, J. McKelvie, Jas. East, E. J. Mellett, H. P. Standley, Prof. E. Brayley Reynolds, J. Willett, G. E. King, and Capt. Rees-Mogg.

THE INTERNATIONAL VETERINARY CONGRESS.

The HON. SEC. said he had received a letter from the Treasurer of the Congress in which he gave a list of the members of this Association who had promised to contribute, and of those who had paid. He saw that only a proportion of their members had subscribed, and the Treasurer said he would be pleased to receive any further donations to the fund.

New Members.—Mr. F. T. TREWIN, M.R.C.V.S., of Watford, proposed by Mr. Villar, and seconded by Mr. Simpson; and Mr. J. W. HOPKIN, of Henley-on-Thames; proposed by Mr. Male, and seconded by the President, were unanimously elected members of the Association.

ELECTION OF OFFICERS.

The PRESIDENT said he believed it was usual for the outgoing President to have the privilege of nominating his successor, and he had very great pleasure in proposing that Mr. J. C. COLEMAN, of Swindon, be their President for next year. (Applause). They had all known Mr. Coleman for years, and he knew no more enthusiastic member of their Association or of the profession. Although a very busy man, he thought his record of attendance at meetings would be as good as that of any member. He had on more than one occasion represented their Society at different functions. (Hear, hear). Mr. Simpson seconded the motion, and it was carried by acclamation.

Vice-Presidents.—Mr. Simpson proposed the re-election of Messrs WILLETT and HANDCOCK. Seconded by the Hon. Sec., and agreed to unanimously.

The HON. SEC. moved the election of the President to take the place of the retiring Vice-President. Mr. Green seconded.—Carried unanimously.

Mr. BROAD, of Marlborough, was chosen to be the other Vice-president, on the proposition of Mr. Coleman, seconded by Mr. Simpson.

Auditor.—The HON. SEC. said he had had a letter from Mr. A. L. Butters regretting very much that he was unable to attend that meeting, and adding that as his eye-sight was getting very defective he thought it would be well that they should change their auditor. He wrote expressing the hope that Mr. Butters would continue to act if possible, but he replied, "I have again considered the matter, and think it would be best for the Association to elect another auditor. I feel sorry to have to come to this conclusion, but under the circumstances I think it the best thing to do."

Mr. SIMPSON said they would all be very sorry to lose the services of Mr. Butters, but he proposed that his resignation of the position of auditor be accepted with regret, and that they express their very hearty thanks to him for the services he had given to the Association for many years. He (Mr. Simpson) was their secretary for seven years, and he always found Mr. Butters a most charming man to deal with.

Mr. MALE, in seconding, said Mr. Butters had always taken a very great deal of trouble in the work, which he had done thoroughly well. (Hear, hear.) He was one of the oldest members of the Association, and he was sure they were all extremely sorry that he was not able to continue his duties. (Hear, hear.)

The resignation was accepted, and the Hon. Sec. was requested to write Mr. Butters expressing the regret of the Association.

The HON. SEC. proposed with great pleasure that Mr. P. J. SIMPSON be elected auditor. Mr. J. C. Coleman seconded, and the resolution was carried unanimously.

Mr. SIMPSON thanked the meeting, and expressed his willingness to act.

Secretary.—The PRESIDENT said Mr. Male had done the work of Secretary and Treasurer thoroughly and energetically—indeed, practically all the work of the Association fell on him. He was sure they did not want any change, and he had very great pleasure in proposing that he be asked to continue in office. Mr. Male was a very busy man, but often busy men found most time to do those things—at any rate his work could not be done better. (Applause)

Mr. TENNANT seconded the resolution, and it was carried by acclamation.

Mr. MALE thanked the meeting very much. He was, he said, quite aware of all his shortcomings. As had

been said, he was fairly busy, and really felt that he had not enough time to do the thing properly, but still, if they were satisfied, he would continue. (Applause.) He would like to acknowledge the great help that Mrs. Male had always given him in the discharge of those duties—indeed she bore the brunt of the work, and but for her he certainly could not keep it on. (Applause.)

Place of Next Meeting.—On the motion of Mr. Allen, seconded by Capt. O'Rorke, it was unanimously resolved that the January meeting of the Association be held at Reading.

NOTES ON THE TREATMENT OF REMOUNTS

By Capt. F. C. O'RORKE, A.V.C.

Mr. President and Gentlemen,—Our most energetic Secretary, Mr. Male, who I am very pleased to see quite fit again after his recent attack of appendicitis, honoured me with the request to read a paper at this meeting. I replied that I would much rather listen to and learn from a paper read by some other member of our Association, but that if he experienced any difficulty in persuading one of you to come forward I would gather together a few notes on my daily work. These may be of interest to some of you. I hope they will bring forth a discussion, and also some useful suggestions from those who have had more experience than myself.

In dealing with the subject that I have selected, I propose to commence from the time that the young horse has been purchased, and deal with the measures to be adopted in order to prevent the occurrence or spread of contagious disease, bearing in mind that many of the horses are already infected prior to purchase.

The remounts which come under my supervision might be grouped into three classes:—

- (1) Officers chargers.
- (2) Troopers or riders, *i.e.*, riding horses for N.C.O's. and men.
- (3) Draught horses (light and heavy).

These three classes can be again sub-divided into different types according to the branch of the service for which they are purchased, *e.g.*, the Army Service Corps are now supplied with "riding" horses which can be used both for riding and draught.

Age. The age of the horse may be anything from four to seven, but the average is five years, and we very occasionally buy a horse three "off" or "rising" four.

Serum Inoculation. The purchase of the horse having been completed he is then inoculated subcutaneously with 30 c.c. of anti-strangles serum and arrangements made for his conveyance to the remount depôt.

The serum, a hyper-immunised horse serum, which is carefully prepared at the Army Veterinary School, Aldershot, and is issued in 30 c.c. phials.

The present method of serum therapy has only been in practice since October, 1913; prior to that date 10 c.c. doses were given—one at purchase followed by three more doses at intervals of a week. Although this treatment decreased the number of cases of strangles and catarrh and the severity of these diseases it did not give such good results as one might have expected. The following statistics are taken from the Annual Statistical and General Report of the A.V.S.:—

ANTI-STRANGLES SERUM.

	1910	1911*
Inoculated	1200	2839
Affected—Catarrh	81	424
Strangles	99	205
Not affected	977	2100
Joined depôt or unit		
affected—Catarrh	35	88
" Strangles	8	22

* The trial of this serum has been continued during the year (1911), but owing to abnormal purchasing of remounts, demands could not be met, and the serum had to be temporarily discontinued during October and November.

Nasal Catarrh.—This is a disease which gives an enormous amount of trouble in a remount depôt, especially amongst the horses which have been purchased in Ireland. One frequently finds at the time of purchase that some of the horses are already suffering from slight catarrh or have recently recovered from strangles, and a large proportion of the remainder, although showing no symptoms, have probably already been in contact and possibly infected.

Let us look back for one moment to the chain of events through which the remount from Ireland has recently passed before arrival at the depôt. Picture him back at his home on an Irish farm in fat, soft condition. From here he may have been taken twenty or thirty miles into a South of Ireland fair, probably in wet weather, too. He was then waited about in the fair, been galloped several times by intending buyers, then having been sold he has to stand about in the streets until his new owner (the dealer) is ready to put him on the train with his other newly purchased horses. During the day he will have had little or nothing to eat. He is then sent up country in a truck to Dublin, or further north, and eventually arrives at his new stables tired and hungry. Here he is crowded up with other horses and overfed. He is next seen by the Army purchasing officers, examined and galloped again. Then his trying journey to England commences, which frequently takes as long as 48 hours, more than half of this time being spent in an open railway truck. On arrival at the remount depôt he looks dull and "tucked up," his vitality has been lowered. Is it any wonder that he develops catarrh or strangles after the severe time he has had and the many sources of infection through which he has passed?

Arrival at the Depôt.—All the horses on arrival are inspected, and if found to be suffering from catarrh, strangles, or ringworm, etc., are picked out and segregated in stables set aside for the treatment of these diseases. The remainder, which are apparently free from disease, are put into other stables which we term the "reception" stables, where they remain until it is considered safe to move them into the main depôt stables. After being watered, fed, and bedded down, they are left to accustom themselves to their new surroundings.

A few hours later each horse's temperature is taken and recorded, and those with a high temperature, or any which have not "fed up," are given a dose of sulphate of magnesia, their throats rubbed with liniment, steamed hay and warm feeds are given. Those which show signs of pharyngitis and laryngitis are given chlorate of potash in their drinking water, in addition to having their throats rubbed with liniment.

The catarrh cases, which have been put into the "catarrh stable," are similarly treated; and the strangles cases, if any, have a damped pad of cotton wool applied to the submaxillary and parotid regions, which is retained in position with a many tailed bandage. The temperature recording is continued for the next few days, and any horse in which a high temperature persists for some hours after arrival, is removed to a loose-box, which is often sufficient to bring the temperature down without further treatment.

Now with regard to the method of feeding on arrival. Many Irish dealers recommend that the horses be fed from the floor instead of mangers, assuring me that by adopting this position that attacks of catarrh are lessened in severity and duration. The explanation being that the nasal discharge escapes more readily, or is more easily expelled whilst feeding in this position.

I cannot say that I have much faith in this belief, but one must not forget that it is the natural position, and also the one in which a horse when suffering with a sore throat will hold his head. I only partially adopt this method by giving the hay feed from the floor, especially when steamed, but occasionally I find the horse will feed better from the manger.

By now the horses, theoretically, have acquired a certain amount of immunity against catarrh and strangles, having a few days previously received 30 c.c. anti-strangles serum. But if a horse is noticed to be developing either of these complaints, and looks like giving trouble, I inject another 10 c.c. of serum.

[Capt. O'Rorke then briefly discussed the uses of vaccine therapy.]

The next important procedure is to prevent the horse developing ringworm, a disease which is very prevalent amongst remounts. For this purpose I use one of the following solutions :

1. Calcium sulphide.
2. Caustic potash.
3. Washing soda.
4. Paraffin emulsion.

Of these preparations I think the calcium sulphide is the most reliable when properly used. But it must be used carefully where the skin is thin between the fore legs and inside the stifle. It can be applied with a spray, or sprinkled on and well brushed into the coat ; I find the latter the better method. With a fine skinned horse or one just clipped the solution must be made weaker, or it may blister the skin. After application, the horse is not groomed for four days. It should then be brushed or washed off, the latter being the easier method, unless the horse has a thick coat, which will be difficult to dry. But it is no easy matter and a rather unpleasant task to groom it off. Although unpleasant to use it is very efficacious not only in ringworm, but also in dealing with lice, psoroptic and symbiotic mange. It must be applied thoroughly, and is better if freshly made. Two applications are sometimes necessary.

2 and 3. Solutions of caustic potash or washing soda are useful and quite efficient in fine coated horses. They are also very useful for scrubbing clipped horses which are found after clipping to be covered with pimples. They assist in removing the dirt and scurf, and dry up any small eruptions which one so frequently finds in horses brought up from grass. The 3 per cent. caustic potash solution readily cures ringworm if applied twice daily for a few days ; it has the advantage, too, of being very mild treatment. Many of the usual remedies are so severe that they make the case look much worse before it is better, and keep it on the sick list longer than necessary.

4. Paraffin emulsion is fairly good as a preventive to ringworm, but if not used with care is inclined to make the coat very scurfy.

Testing with Mallein.—On the second or third day after arrival the horses, if feeding well and temperature remaining normal, are tested with mallein. It is seldom that they do not pass the test but occasionally one meets with a doubtful and unsatisfactory reactor. Several I have had to re-test three times before deciding their fate. Two of these eventually had to be destroyed. At the post-mortem examination they showed very slight pulmonary lesions, but the diagnosis was confirmed later when the bacillus mallei was cultivated from material obtained from the lungs.

Shoeing.—Another important item is to attend to the horses' feet. Their hind shoes having been removed for travelling in trucks, the feet are frequently very much broken, and a certain number of them arrive lame or foot-sore. The front feet, of course, require attention too—the feet are often dumped, and the periople invariably rasped off.

I must now conclude by thanking you for the most attentive and patient way you have listened to my efforts to interest you this evening.

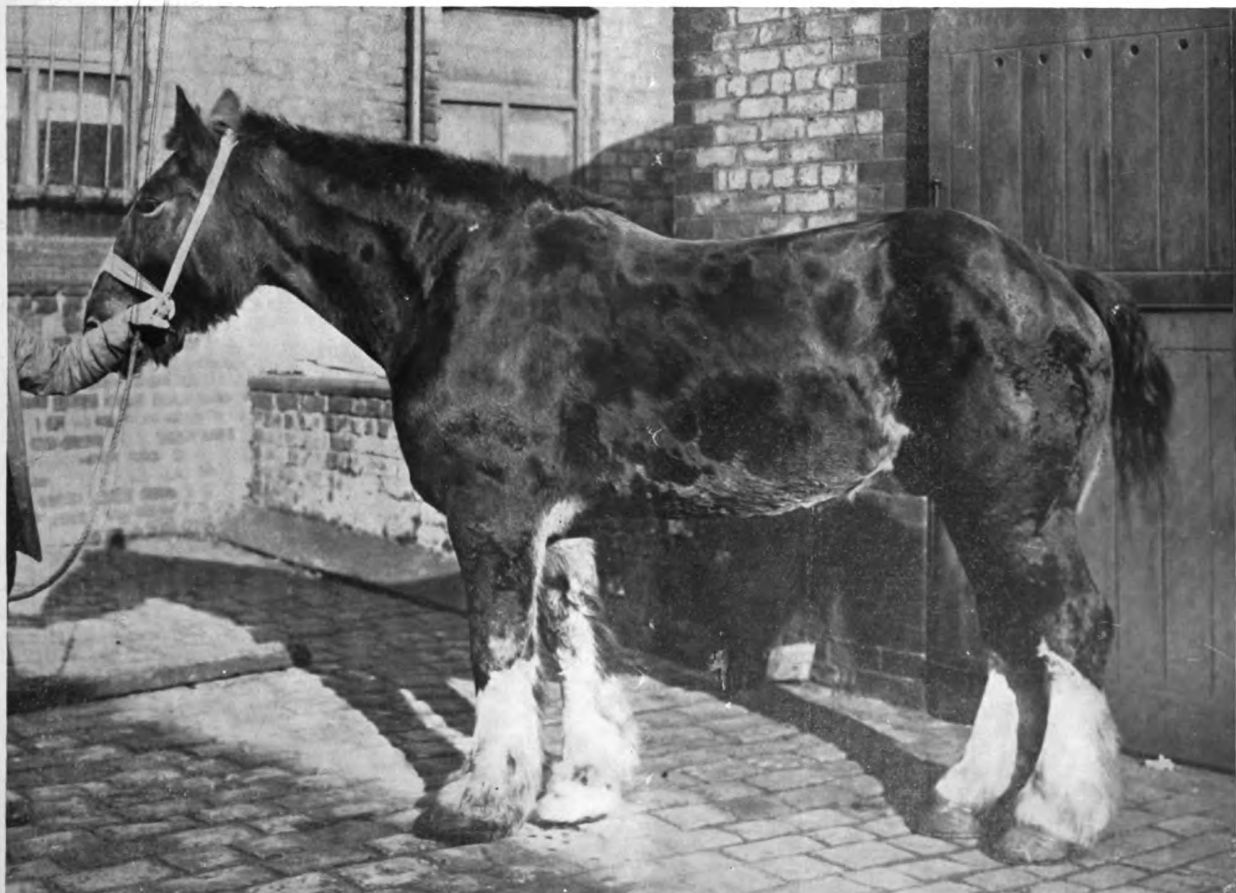

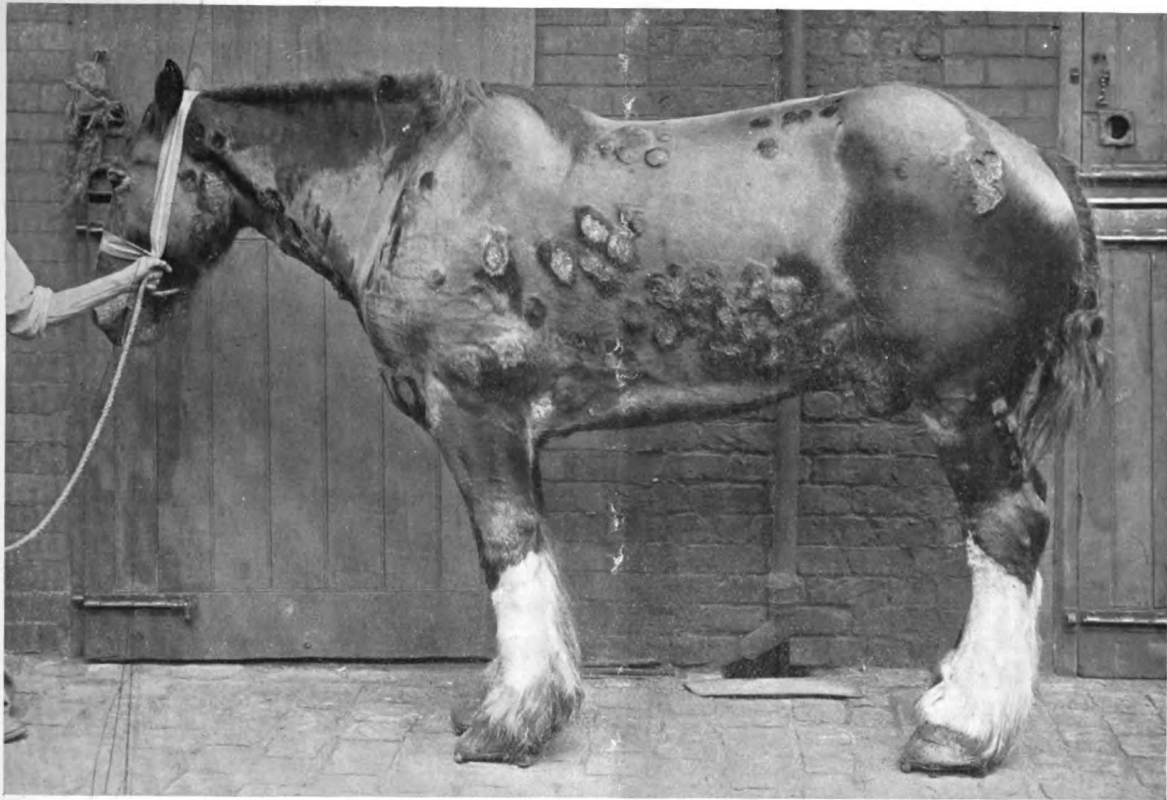

DISCUSSION.

The PRESIDENT was sure they had all listened with great pleasure to Capt. O'Rorke's very able paper. (Hear, hear.) The use of mallein was known to them all to be very interesting, and sometimes very puzzling. Capt. O'Rorke said that in his treatment of strangles he was placed in a very favourable position as compared with the private practitioner, who very often would not be able to carry out the treatment in the way he did, which was more the pity for the private practitioner.

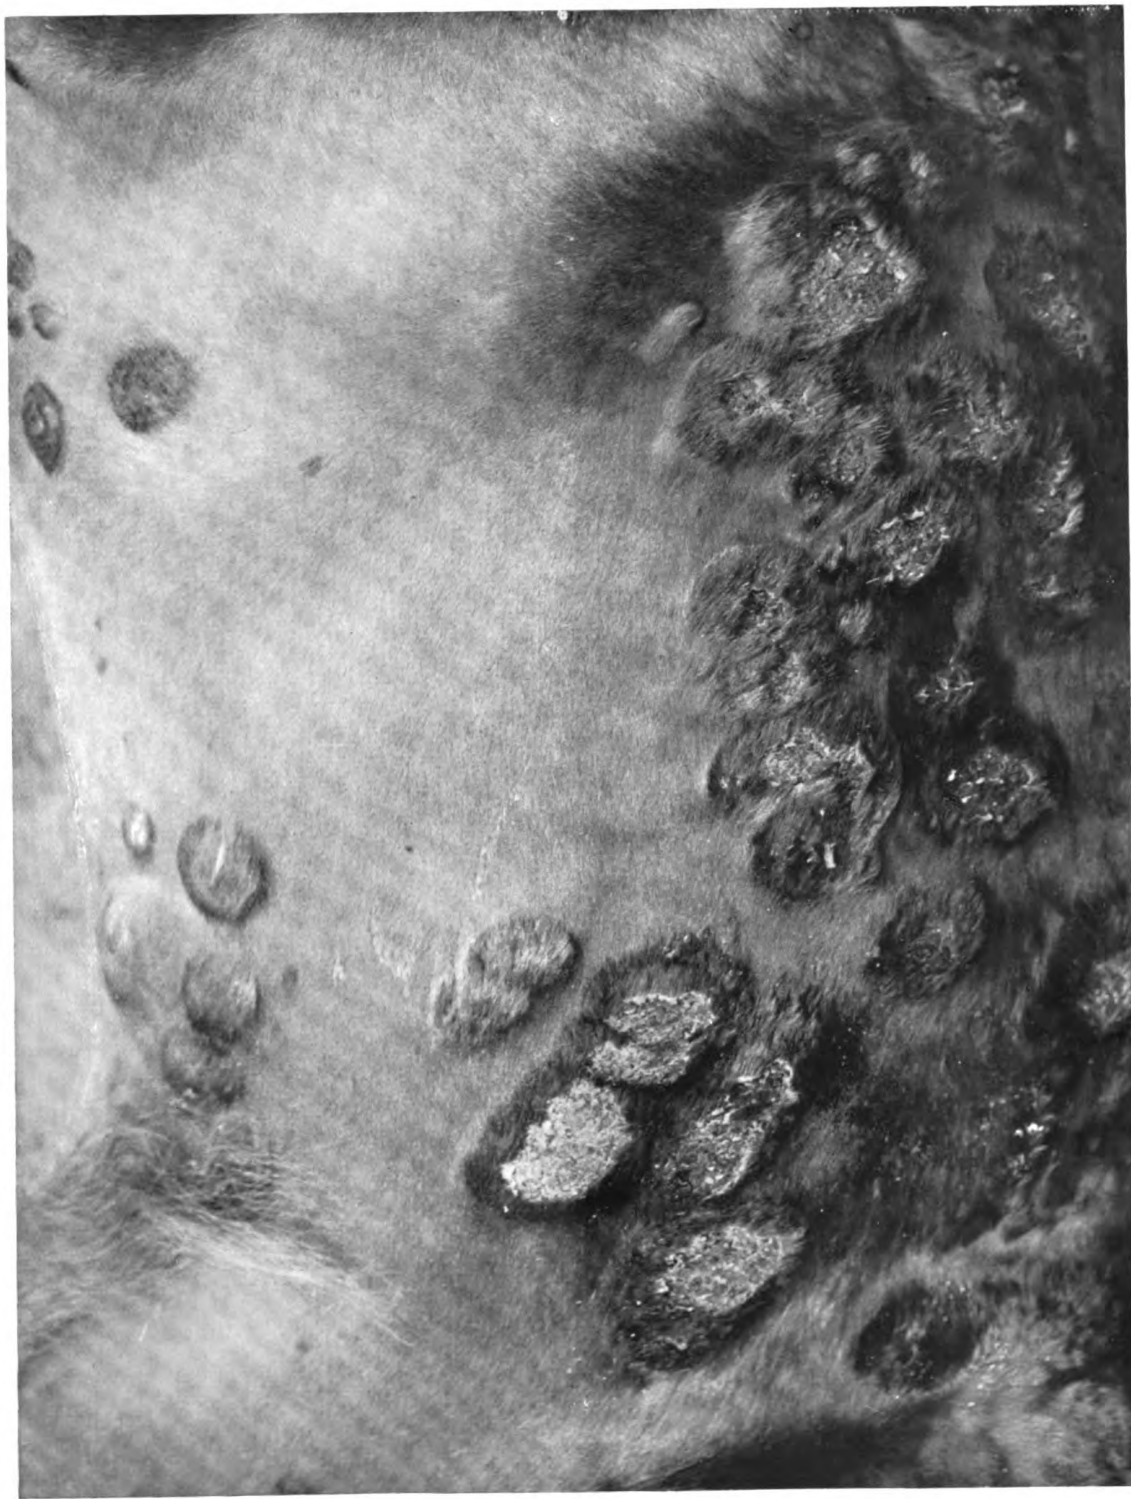

Mr. SLOCOCK : He was an Inspector in Middlesex, and in their early days those inspectors were very much indebted to the late Mr. Hunting for the assistance he gave in post-mortems, for he was always ready to help his neighbours. (Hear, hear.) In some cases he (the speaker) had had no temperature reaction twice ; in others no local reaction at all, but these horses had "been in bad company," and in many of these cases he therefore had reason to suspect glanders. In many of those cases post-mortem lesions were very well marked. The extent of the reaction to mallein in no way indicated the extent of the lesions present. They could get really a nice glanders post-mortem in a case in which they had had very little elevation of temperature. He (Mr. Slocock) had the very first test of mallein that ever came into this country in his practice. He had a horse with a lesion in the face, and he felt satisfied it was a glanders lesion. He got the indurated gland, and went to the College and mentioned it to Prof. Penberthy, who brought a dose of mallein which he injected, and gave him instructions as to when to take temperatures, etc., and afterwards he (the speaker) was able to say that that horse gave a very typical reaction. It belonged to a market gardener ; it was isolated in the stable, and worked by himself in his own cart and harness. He received three doses of mallein at different periods, and apparently made a perfect recovery. Eventually he got back into his team, and worked from Feltham to Covent Garden regularly until he became a pensioner, and the ultimate cause of death was a twisted gut. They might take it for granted that that horse was cured of glanders. He himself believed that mallein was a curative in some cases—but in some only. Dealers were, to his mind, men to be taken note of, for they had had vast experience. He thought there was a great deal in the idea that affected horses should be fed from the ground. Many dealers would not buy a horse from Ireland except in the summer months. If a batch of horses had been travelled together they could be turned into the same field, and left out for ten days or a fortnight, and there was very little trouble with them. Even with valuable horses he thought that was worth all the risk.

We seemed to get more ringworm from Ireland than from anywhere else, whether in horses or in cattle. For that complaint he believed they got the best results from using a greasy dressing—vaseline was good used alone. One of the best dressings he knew for confluent ringworm was mercurial ointment and soap worked down together, which was scrubbed in and left on for five days. Nothing survived that, except in the parts which the dressing had not thoroughly reached. That dressing was recommended him by his friend, Mr. Willett.

Mr. TENNANT added his thanks to Capt. O'Rorke for his very interesting remarks ; and went on to ask him a few questions on his paper. He thought they might take it that the serum treatment was not satisfactory on the whole, but that it was so in those cases that developed strangles and catarrh, which were milder on

A RARE SKIN LESION, *Note by Messrs. Berry and Pillers.*

Lesions behind shoulder. (Enlarged).
A RARE SKIN LESION. Note by Messrs. Berry and Pillers.

the whole, and of shorter duration. He would also ask whether age had any influence in the cases—whether young horses were proportionately more affected?

With regard to Mr. Slocock's remarks about parasitic mange, he (the speaker) generally washed the horse all over, first, with ordinary washing soda, got him dry, and then lathered him all over with mercurial soap, leaving that on a week, and then brushing it off.

As to the mallein test, some years ago he had seven or eight horses react to mallein, two of which were kept and tested once a month for six months, when they ceased to react, and he destroyed one. The other seven were all killed by order, and although he sent a special request, he was not allowed a post-mortem on one of them.

[The President being obliged to leave the meeting at this stage, Mr. J. C. Coleman took the chair].

Mr. SIMPSON said they ought not to let their President go without thanking him sincerely and heartily for the way in which he had conducted the business of the Association during the year. (Hear, hear).

Mr. SLOCOCK seconded. They had, he said, been most happy in their selection of a President for the past year, and it had been a great pleasure to them to sit under such an amiable and affable gentleman. (Applause).

The vote was carried by acclaim.

Mr. WYLLIE thanked those present very much for their kindness. Anything he had been able to do had been a pleasure. He hoped the Association might go on and prosper, and that the future meetings might be better attended. (Applause).

Mr. J. C. COLEMAN, from the chair, said he had a good man to follow, and he thanked them for putting him in the position. He would like to thank Capt. O'Rorke for his very interesting paper. The large percentage of cases affected seemed unsatisfactory, but when they considered the nature of the disease and the number of horses coming over, it was easy to realise that one case of strangles might affect the lot. With regard to ringworm, he had found calcium sulphide very successful, but rather irritating. The preparation he used with great success was diluted nitrate of mercury in conjunction with chrysarobin. His objection to Mr. Tennant's method of washing all over was that he had found that the less they did in disturbing the sites of affection the better, and he thought that washing rather disseminated the disease.

Mr. HOPKIN considered the best way of treating parasitic mange was to prepare the skin, for which he used "Rinso" (Hudson's) with a couple of ounces of Lysol in the bucket. Then he used mercury and soap, but not with the success of which Mr. Slocock had spoken. If they got all the scurf off, he considered one or two dressings at the most a certain cure, with a preparation containing mercury ointment and oleic acid.

Mr. UPTON related a case of poisoning among calves dressed over with mercurial soap for ringworm. This was done by the owner contrary to his advice, and when called in he found a number of them dead and others in *extremis*. He showed how difficult it was to eradicate ringworm from premises occupied by cattle. Even if carefully disinfected the disease was sure to recur.

Mr. MALE thanked Capt. O'Rorke personally for giving his paper, thereby helping him out of his difficulty.

As to strangles, he had been trying himself to find something which would prevent that disease in horses. Capt. O'Rorke's preventive measures were evidently good. Was the serum he used the antistreptococcus serum? What did he consider to be the period of incu-

bation of strangles, and when would he consider it safe to remove horses from the reception stables?

With regard to skin diseases, were they all talking of the same disease? Evidently they were not. Some people could cure horses affected with mange with one dressing, but he had seen cases that had never been cured. He hoped that somebody would read a paper very shortly on the different diseases which affected the skin of horses. (Hear, hear).

He had always looked on ringworm as more or less of a local disease. If it was a local one, why was a horse washed all over? Were they talking about a contagious disease which was called American pox, or German pox, which they got among remount and dealers' horses? It is characterised by an exudate and the hair coming off in little round patches, usually on the quarters, but all over the animal in some cases; the hair after a time begins to grow again even without treatment. He had found mercurial soap very good in the treatment of mange.

Mr. SIMPSON would like to ask Capt. O'Rorke if, in his opinion, sufficient doses of the serum had been used, as he said that the dose had been greatly increased latterly. He had himself found polo ponies from Ireland troubled with some disease which was certainly not strangles, but was apparently a form of influenza. It had struck him whether a larger dose of serum would not be more valuable in the case of animals five years old and upwards. If horses had been issued to a unit, were they again treated with serum? With regard to the dressings for mange, he had tried some of them, but had failed to find one that would cure a good case of parasitic mange in one dressing. Those cases generally came under his observation as an Inspector, after they had been "spotted" by a policeman in the street, and it was generally two or three months before one cared to declare the animal free.

Mr. HOPKIN added that a mare that had been treated for three months with various dressings, was cured with one application of the dressing he had mentioned.

Capt. O'RORKE replied on the discussion. He much appreciated what Mr. Slocock had said with regard to mallein. He (the speaker) frequently got a case like the one to which he had referred. Among 50 or 60 horses they frequently got one which looked splendid at the beginning of the test. A little while ago he had to test 200 horses twice, some of them having been in contact with a case of glanders, and cases of glanders had not occurred amongst them. They put aside about five out of the 200, and re-tested those again. A London Inspector came to see them, and one was destroyed, but they found at the post-mortem two nodules in one lung and one in another, which was very disappointing. He had had two similar cases since he had been in his present appointment. He had to keep his horses at first in the reception stables. In reply to Mr. Slocock, who said ringworm resembled mange, in the cases of ringworm he got, there was no irritation whatever. He was speaking more or less of preventive methods when he spoke of calcium sulphide. His idea was to keep disease out of his depot, and so he dressed a horse over with calcium sulphide. He used $\frac{1}{2}$ to 1 pint for a horse. As to vaseline and treacle, dealers had reported to him that they sometimes had cured with plain lard, but he had never heard of treacle being used for this purpose. Sometimes it was very easily cured, sometimes not. He certainly thought that age had a lot to do with strangles, although he occasionally had seen old horses with strangles.

Mr. J. C. COLEMAN thanked Capt. O'Rorke for his very interesting paper, and proposed a hearty vote of thanks to the essayist.

This was seconded by Mr. Male, and carried with acclamation.

SPECIMENS.

Mr. HOPKIN showed two specimens which proved of considerable interest to the members. One was a calculus which he had cut from the cheek of a cob, above the fourth upper molar, and which was most unusual both for its size, shape, and position; the other being part of the heart of a cob in which, on post-mortem, he had found a large vegetative growth attached to the tricuspid valves.

Mr. Hopkin was cordially thanked, on the call of Mr. Male, seconded by Capt. O'Rorke, for bringing his specimens forward.

The members were then served with tea, at Mr. Male's kind invitation.

G. P. MALE, Hon. Sec.

NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION.

A general meeting was held at the New City Abattoir, Stewart Street, Belfast, on Friday, the 31st October, when the chair was occupied by the President, Mr. J. A. Jordan, M.R.C.V.S., City Veterinarian. The following members were present: Messrs. J. J. Ross, J. Gregg, J. M'Lean, A. Stringer, and J. Ewing Johnston, Belfast; J. M'Aleer, Portadown; Samuel Little, Dungannon; Jas. Devlin, Coalisland; W. S. Lamont, Cookstown; W. C. M. Smith, Newry; J. A. Thompson, J.P., Lurgan; A. J. Logan, Ballyclare; H. M'Connell, Armagh; A. M. Crichton, Lisburn; J. A. Gault, Ballymoney; J. W. Peatt, Cootehill; J. W. Morrow, Coleraine; J. Kernohan, Ballymena; F. R. M'Roberts, Comber.

Visitors: Messrs. J. Purdy, Belfast; M'Guinness, B.A., E. W. Little, H. Hannan, P. W. D. O'Connell and J. M'Enamin, of the Department of Agriculture, and Prof. Hobday, London.

Apologies for inability to attend were received from Messrs. J. B. Dunlop, Alex. Munro, T. C. Taylor, and J. C. Kyle.

Before proceeding with the ordinary business of the Association, the President said it was his pleasing duty to extend a very hearty welcome to our distinguished visitor, Prof. Hobday, as it was not often that we were favoured by the company of such an eminent member of the profession. It was very kind of the Professor to come and give us an interesting lecture and practical demonstration, and he was sure they would all appreciate it.

On the motion of Mr. Ross, seconded by Mr. Thompson, the minutes of the last meeting, as published in *The Veterinary Record*, were taken as read.

New Member. Mr. E. W. LITTLE, D.A.T.I., was proposed by the President, and seconded by Mr. J. Ewing Johnston.

Correspondence. The Hon. Sec. submitted a letter received from Mr. W. Shipley, Hon. Sec. to the Victoria Veterinary Benevolent Fund, asking for a continuance of the Association's support. Messrs. Thompson and Jordan having supported Mr. Shipley's appeal, Prof. Hobday said, if permitted, he would like to mention how sorely they were in need of financial aid, and how impossible it was for them to meet the many necessities so constantly being brought to their notice, and while very grateful for the support already given, it would be very pleasing to them to see Ireland's contribution increased. The Treasurer was authorised to forward the usual subscription to Mr. Shipley.

"SOME ABNORMALITIES MET WITH BY THE CRYPTORCHID OPERATOR."

Address by FRED. HOBDAY, F.R.C.V.S.

(The lecture was illustrated by about 20 photographs or drawings; these were not only of great interest from a pathological point of view, but were really works of art.)

The lecturer said that he ought first to thank the Association for having accorded him the honour of presenting his paper, and secondly he had to congratulate them in the lead they had given to other similar societies in the British Isles in the fact that they were permitted, through the influence and kindness of their President, Mr. Jas. A. Jordan, to hold their meetings in that building. It was an example which ought to be followed in every town in England where such a building existed.

Cryptorchidism was a subject full of interest to every one who had to do with castration, and to every member of the profession who intended to become a specialist it was one of the things that would always loom in the forefront. The abnormalities of cryptorchid work were more in variety than those met with in any other operation known to veterinary science. He would show them that night a number of photographs, taken from actual specimens, and every abnormality he would speak of he had met with himself during the course of some four or five hundred operations. The study of such abnormalities was both interesting and instructive. To the enthusiastic "rig" operator there was nothing more fascinating than to be presented with the abdominal surface of a colt, the scrotal portion of which presented an even surface unmarked by any suspicion of scar, and whose history, until it had come into the possession of its present owner, was practically untraceable. Even the presence of a scar might mean nothing other than that an attempt at castration had been made and failed, or perhaps it had been made fraudulently, whilst a careful digital examination revealed that nothing solid could be touched. Extreme reticence was wise, and even after a most careful examination an experienced cryptorchid operator usually gave his opinion cautiously, because in some cases what was thought to be testicle might turn out when cut down upon, to be merely an enlarged or varicose vein, or perhaps the epididymis or spermatic cord. The old adage, "things are not always what they seem," applied more to cryptorchid operation than to any other operation in veterinary surgery. There was no operation which veterinarians were called upon to perform which could be so truly likened to the "lucky dip" at a bazaar.

With the various methods of operating and sites selected for the preliminary incision they were already familiar, and he would here confine himself solely to the abnormalities which might be met with, for it was there that the operator had his chance for displaying common-sense and, above all, coolness in an emergency. The latter qualification was essentially necessary in "rig" operating, for when once the abdomen of a big animal like the horse had been entered, it was essential that every precaution should be taken to avoid accident and to restore the abdominal wall to its previous condition as far as was surgically possible.

Every "rig" presented some abnormalities, otherwise the services of the specialist would not be called in, and he purposed to deal with these under three heads:—(1) Abnormalities of the inguinal testicle. (2) Abnormalities of the testicle found in the abdomen. (3) Absence of testicle.

Of course the history of the colt should first be investigated, but too much stress should not be placed upon

that history, for it was often unreliable. As a rule it would be found that the animal had been purchased at some sale or market as a gelding, the owner not finding out his error until he reached home and certain troublesome tendencies were revealed; or it might be that the colt was sold straightforwardly as a "rig," and the fact—or otherwise—known that one testicle had been removed. In regard to the latter the cryptorchid operator should be careful not to be misled.

On several occasions it had been his lot to find the missing testicle on the side from which both the owner and the local veterinary adviser had emphatically asserted that it had previously been removed. It was easy to forget these things unless a written note was made at the time, and the operator should always finally fall back upon his own examination. A careful digital examination, with the presence of a scar, would generally reveal whether or not the inguinal canal contained the cord from which the testicle had been removed. Great care, however, should be taken not to mistake this for an enlarged or varicose inguinal vein, which, if punctured, would give great trouble and cause dangerous hæmorrhage. After making the incision through the skin, a search up the inguinal canal might reveal a small and elongated testicle, or perhaps one of almost normal size. Here experience alone determined whether what was removed was epididymis or the complete organ. He frequently came across cases in which the epididymis was in the canal and the body of the testicle was in the abdomen, and if the former only was removed the horse would soon "rig" again. If it were possible, the body of the testicle should be drawn into the canal, or the epididymis put back into the abdomen, when the two could be included in the chain of the ecraseur at the one time; but that was not always possible, and each might have to be taken off separately, the epididymis from the canal, and the body of the testicle from the abdomen. It was not common to meet with cysts, teeth, or other abnormalities except deviations from the normal in size and shape, in purely inguinal testicle. Nature reserved those for the abdominal specimens.

ABNORMALITIES OF THE TESTICLE FOUND IN THE ABDOMEN.

Here curiosities were often met with, for the testicle might be as small as a filbert or as large as a Rugby football; it might be as hard as a bullet or as soft as a balloon, and its interior might contain almost anything—hair of various colours (generally black or brown), bone, perfectly or irregularly shaped molar or incisor teeth, cystic fluid, the *Strongylus armatus*, or tumour tissue. He had personally met with all these, and in a specimen obtained recently the one testicle contained everything enumerated except hair. The tumour tissue might be fibroma or embryonic, or it might be sarcoma, whilst one specimen, which the curator of the museum of the Royal College of Surgeons (Dr. Shattock, F.R.C.S.) gave him to understand was unique in either man or animal, contained a lipoma.

For the withdrawal of the fluid from the cystic portion, he had had a small cannula made with sharpened edge and with a long piece of tubing attached. This he sterilised in the usual way, and introduced into the abdomen in the hollow of his hand; it was a simple and useful contrivance. But without it the operator need not have any hesitation about scratching through the cyst wall with a finger nail, and thus allowing the contents to escape into the abdomen. This he had done fully a dozen times, and neither peritonitis or other trouble had followed. He concluded, therefore, that the contents of the cyst were aseptic.

ABSENCE OF ONE OR BOTH TESTICLES.

Such cases, of course, were rare, but an operator who had many cases of "rig" horses was bound to meet them

on occasions. He himself had had practical experience of such in three cases. One was the case of a valuable racehorse. The animal was a true anorchid, the ends of each cord terminating close under the loins in a small bulb of fat. The facts of this case were verified on post-mortem examination by Prof. M'Fadyean.

In another instance, a monorchid cart colt, the right testicle weighed 12½ ounces, and was quite twice the normal size, whilst on the left side the cord terminated imperceptibly into the peritoneum, there being no sign of any testicle or epididymis.

In conclusion, the lecturer said that he had dealt with the chief abnormalities which the cryptorchid operator had to bear in mind, but in all cases a successful sequel was possible, provided proper precautions had been taken in the operation, and careful attention paid to all the antiseptic details. He could not too strongly enforce upon their attention the necessity for the latter. For his own part, he had great faith in iodine as an antiseptic. This was a revival of a method adopted by old farriers years ago as an antiseptic in the case of wounds. He usually painted the part to be incised with a tincture of iodine and allowed it to dry. In the last three years he did not think that he had washed a single horse before operating.

At the conclusion of the lecture, on the invitation of the Chairman, questions were asked by Messrs. Kernohan, Ballymena; Thompson, Lurgan; Crichton, Lisburn; and Gault, Ballymoney.

Prof. HOBDAY, in reply, said that most of the queries could be best answered at the operation. He would be glad then to explain anything he had not made clear. One learned more from a practical demonstration than from many lectures.

In reply to Mr. Crichton, he said he preferred the tincture of iodine to the liniment; the latter was liable to blister.

It was suggested by Mr. Ewing Johnson that Prof. Hobday should give some particulars about "Roarers." In response to this, the Professor said he was afraid that that was rather an extensive subject. Personally, he had now performed the operation on 807 individual animals. He had followed up 100 of these year by year, and some of them had now passed the fourth season without a return of the complaint. In fact, most of them were still running, and he had not a single unpleasant letter from an owner. Ten per cent. of the cases had become sufficiently sound to be passed by the average veterinary surgeon, and he was prepared to say that—let the cases be as bad as it was possible to find—after the operation, eighty per cent. of the hunter class would become useful horses, and work without distress; and in the case of comparatively slow working carriage or cart horses, he would put the percentage as high as ninety or ninety-five. He knew of over 50 owners whose horses had realised over £100 each after the operation. He could name five which this year had won point-to-point races. He admitted there had been a few relapses, but he had only heard of nine such relapses up to the present time, and that, out of 807 cases, was not a large proportion. He was proud of the fact that in this branch of veterinary surgery they were two and a half years ahead of the Germans, although the latter were now quite enthusiastic about it.

Mr. EMERY in moving a vote of thanks to Professor Hobday, said he was sure that they had all most thoroughly enjoyed the lecture delivered to them by a gentleman who was a past master in the subjects dealt with. It was now a good many years since he first saw Mr. Hobday, who was then a junior student, and who even in those early days, gave promise of becoming one of the best men in the profession. That promise had been amply fulfilled. He had the greatest pleasure in moving a very hearty vote of thanks to the lecturer.

This was seconded by Mr. Thompson (Lurgan) in a few well chosen laudatory words, and passed with great enthusiasm.

Prof. HOBDAV, in acknowledgement, thanked the members for their patient hearing, and said he thought it a privilege to come before that Association in Ulster, and especially at a time when all England was looking towards the Province of the North. (Laughter and applause).

THE LATE WILLIAM HUNTING.

Mr. EMERY said he had a very sad duty to perform. He referred to the lamented death of Mr. Wm. Hunting, F.R.C.V.S., and in moving a vote of condolence with the deceased gentleman's relatives he said that he was sure they all felt that they had lost a great friend, and the profession had lost one of its most devoted and brilliant members. They all knew the good work the late Mr. Hunting had done in establishing *The Veterinary Record* and conducting it in such an able and impartial manner. They all knew how frequent a contributor he had been to the proceedings of such societies as theirs; his papers were able, often entertaining, and always instructive. His work on "Glanders" was of the very best and his interest in the welfare of our profession was lifelong. We can now say of him:

"Life's work well done,
Life's race well run,
Now cometh rest,"

Mr. KERNOHAN, in seconding, said he had known the late Mr. Hunting intimately for many years and could endorse everything that had been said of him. He was

a gentleman who gave of his best to the profession he loved, and it was to be regretted that during his life some greater recognition of his great services to his profession and his country had not been awarded to him.

Mr. GREGG said he wished to support the vote. He had not previously heard of Mr. Hunting's death, and it came as a shock to him to know that they had lost one of their greatest men and his old personal friend, though it was not altogether unexpected, as when in London recently he saw Mr. Hunting walking through the College and he was greatly struck with his altered appearance. As had been truly said, the late Mr. Hunting had done good work, and his works would live after him. The vote was passed in deepest silence, all members standing.

An adjournment was made to Messrs. Ross and Johnston's commodious and admirably equipped premises at May Street, where Prof. Hobday successfully performed two operations, one upon a cryptorchid and the other on a "roarer."

During the course of the operations Mr. Hobday explained his methods step by step, and a more lucid exposition and clearer demonstration could not have been made. As to the operations, they were performed in an expert manner by an expert.

A most interesting and successful meeting was brought to a close by a very hearty vote of thanks to Messrs. Ross and Johnston, every person present unreservedly voicing their thanks, as it was felt that these gentlemen were really instrumental in affording the opportunity for such an excellent lecture and demonstration.

FRED. W. EMERY.

FELLOWSHIP DEGREE.

A meeting of the Board of Examiners for the Fellowship Degree was held at the College, 10 Red Lion Square, W.C., on Saturday, Dec. 6th. The following is a list of the successful candidates, together with the titles of the respective theses:—

J. BASIL BUXTON, "Veterinary Serum Diagnosis,"
H. TUDOR HUGHES, "Equine Tuberculosis."
H. M. HOLLAND, "Fistula."

The Examiners were Prof. Macqueen, Messrs. Malcolm and Woods: Mr. W. J. Mulvey in the chair.
FRED BULLOCK, Secretary.

EXAMINATIONS IN DUBLIN,

At a meeting of the Board of Examiners held in Dublin on December 8th for the Written, and on December 9th and 10th for the Oral and Practical Examinations, the following gentlemen passed their Final Examinations:—

Mr. J. R. Ellison	Mr. E. S. Mulcahy-Morgan
D. J. O'Byrne	M. H. Reid
A. E. Brandon	J. A. Shannon
St. J. C. P. McFarlan	

The following passed their Third Examination:

Mr. I. C. J. Blake *	Mr. G. J. Delaney
T. F. Donworth	R. Hans
L. A. Herbert	

The following passed their Second Examination:

Mr. P. J. Dunne	Mr. M. McCartin
T. J. Kenny	T. O'Connor
G. McElligott	C. O'Driscoll
W. A. J. Flanagan	

The following passed their First Examination:

Mr. T. A. O'Brien	Mr. H. C. I. Kelly
T. C. J. Roark *	J. P. Rice *
W. Walsh	

Marked thus * passed with Second Class Honours.

Right of Admission to the Law--Appeal Court Decision.

The appeal was brought by Miss Gwyneth Marjorie Bebb, daughter of the Rev. Dr. Bebb, principal of St. David's College, Lampeter, from a decision of Mr. Justice Joyce, given against her in an action to establish her claim, under the Solicitors Act, 1843, to be admitted to the preliminary examination of the Law Society, with a view to becoming a practising solicitor. Mr. Justice Joyce's decision was based on precisely the same grounds as the decision of the Court of Appeal.

The contentions put forward by Lord R. Cecil, K.C. (with him Mr. R. G. Wright), on behalf of Miss Bebb, were:

That unmarried women have *prima facie*, apart from any special considerations, the same legal rights as men, subject to certain exceptions.

That at common law there is nothing to prevent women being admitted as solicitors.

That the fair construction of the statutes on the subject favour their right to be admitted.

Sir R. Finlay, K.C. (with him Mr. Hughes, K.C., and Mr. Tomlin), resumed on behalf of the Law Society. He referred to a case heard in the Court of Session affecting the admission of women as students in the University of Edinburgh, and quoted from the judgment of one of the majority judges to the effect that no instance had occurred since the establishment of the University, of admission being claimed by women until that time. The case was even stronger in regard to solicitors in England, because their foundation went much farther back. Women were ultimately admitted to the University of Edinburgh by a statute of 1889. Council also cited the case "Nairn v. University of St. Andrew," which came to the House of Lords from the Court of Session. The decision was to the effect that women graduates were not entitled to vote for a Parliamentary representative of the University.

With regard to the argument of Lord R. Cecil that the profession of attorney was not a public office, he submitted that from the time the profession became recognised, under 2 George II., ch. 23, the office was of a public nature, carrying with it the right to fill certain offices, including that of Master of the Supreme Court. One could not help thinking that there was sound reason in the common law upon this subject. Obviously, it would work a revolution in chambers if women were allowed to appear before the Masters, for he did not suppose there was a Master living who would refuse more time to a pretty girl who had clearly already got to the end of her tether. (Laughter.) The common law was based upon common-sense in saying that in dealing with legal questions, such as solicitors were required to deal with, men only should be admitted. There was after all a broad distinction between the proper functions of the two sexes. The common law, with the common-sense which had always characterised it, recognised that distinction, and there was nothing in the Act of 1843 which could set it aside.

Mr. Hughes followed on the same side. At one time all the sixty Chancery clerks were compelled to be celibates, because they had originally been in Holy Orders, but gradually that practice fell into disuse, except in the case of six chief clerks, each of whom had ten clerks under him. Ultimately the six began to feel that they were hardly treated in not being allowed to marry, and when Henry VIII. was on the throne, thinking that he might be sympathetic in a matter of that kind—(laughter)—they applied for permission to marry, and 14 and 15 Henry VIII., ch. 8, was passed enabling them to marry. In the old time these clerks were sometimes referred to as "bachelors." They acted as the attorneys of all parties in Chancery, but he did not think they were exactly attorneys as we know them now.

Lord Justice Phillimore: They were more like proctors. No one has told us much about the origin of solicitors. I take it there were solicitors who solicited the Lord Chancellor for the exercise of his discretion and grace in cases where equity ought to interfere. I suppose they had ultimately to instruct one of the sixty clerks to act for them?

Mr. Hughes: Yes.

Lord Justice Phillimore: When did they first become a profession?

Mr. Hughes said they were mentioned so far back as 1605 as "another class destined like Aaron's rod to swallow up all the rest." (Laughter.)

REPLY.

Lord R. Cecil replied. Apart altogether from previous history, the Act of 1843 gave a right to "persons" to be attorneys or solicitors, and it defined "persons" as subject to qualifications as to context and subject-matter, including women, just as the Factory Acts gave

women the right to be inspectors. It was therefore for the Law Society to show that there was a disability before 1843, and if they could not show that, women had a right to be admitted. There was no evidence in the English Law of any general disability of unmarried women.

The evidence that women had not hitherto been solicitors showed nothing in itself; it clearly did not show that they were now disentitled. There was really no legal right to called to the Bar. Lord Mansfield declared that the Inns of Court were mere voluntary societies, and that their conduct in regard to admission was subject to the control of the judges. Any one who was refused admission had a right to appeal to the judges.

Lord Justice Phillimore: If you were a solicitor, have you not in certain circumstances a statutory right to be called to the Bar?

Lord R. Cecil: I think that is only one of the regulations.

Lord Justice Phillimore: There is a statutory power for a barrister to become a solicitor, which is another matter.

Lord R. Cecil said with regard to the common law and common-sense, if they were to bring common-sense into the matter it was perfectly clear that in a country where women might appear as factory inspectors before a court, and where for years they had been entitled to exercise the duties of solicitors' clerks, there could be no special reason why the great mass of non-contentious business of a solicitor could not be as well done by women as by men. If common-sense was to be considered, he submitted it told more in favour of the appellant than of the respondent.

JUDGMENT.

The Master of the Rolls said: This appeal raises a very important point as to the right of woman to be admitted to the profession of solicitor. The plaintiff seeks a mandamus or order requiring the Law Society to admit her to the preliminary examination. The Law Society is a modern creation by statute. The right which plaintiff claims depends upon the Act of 1843. The argument adduced is that in the Act certain statutory obligations are imposed upon the Law Society requiring them to admit any "person" who complies with certain conditions, and plaintiff points to the words, "every word importing the masculine gender only shall extend and be applied to a female as well as a male . . . unless . . . it be otherwise specially provided, or there be something in the subject or context repugnant to such construction."

It has not really been contended by Lord Robert Cecil that there is anything in the Act which destroys or removes an existing disability. What we have to consider is whether at the date of the passing of the Act a woman was under a disability to become an attorney or a solicitor. Three grounds have been alleged to prove such disability. It is said that Lord Coke, 300 years ago, said that a woman is not allowed to become an attorney. Coke was plainly dealing with the profession of attorney, which had been recognised by statute, or to a large extent created by statute, between 400 and 500 years ago. But apart from what Coke said, no woman has ever been an attorney, or, until now, has ever applied to be one.

There is uniform and uninterrupted usage, which is the foundation of the greater part of the common law of this country and which we ought beyond all doubt to be very loath to depart from. I cannot therefore help thinking that, although we have listened to a most interesting discussion as to what women can do, all that is really beside the mark. I decide this case simply on the ground that, in my opinion, there was at the date of the passing of the Act of 1843 a disability on

the part of women to be attorneys, and that the Act confers no fresh and independent right, because it does not destroy a pre-existing right. I assent to this, that, in point of intelligence, education, and competency Miss Bebb, who is a distinguished Oxford student, is at least equal to a great many, and, probably, far better than many, of the candidates who will come up for examination. But that is not before us. Our duty is to ascertain what the law is, and I disclaim absolutely any right to legislate in a matter of this kind. That is for Parliament, and not for this Court. I think the appeal must be dismissed.

USAGE.

Lord Justice Swinfen Eady: I am of the same opinion. Lord Robert Cecil has entirely failed to convince me that the profession of a solicitor is now open to women. It has been pointed out that anciently in England parties to a suit had to appear in person or by a deputy. Coke points out that by the common law a plaintiff or defendant could not appear by attorney without the King's special warrant by writ or letters patent. There were, therefore, but few suits. Then, gradually, in course of time, the profession of attorney arose. The exact date when there were attorneys by profession has not been made to appear, but they certainly existed before 1402, because in that year a statute was passed governing attorneys. After reciting the damage and mischief done by a great number of attorneys "ignorant and not learned in the law," it enacted that all attorneys should be examined by the justices. From that time to the present no woman attorney has ever existed.

What is the effect in England of long-continued usage—usage through the centuries without departure in any single instance? It has been put in this way—"What has been commonly received and acquiesced in as the law raises a strong presumption as to what the law is, and imposes the burden of proving that that is not what it is understood to be." In my opinion, it is sufficient to rest this case upon the inveterate practice of centuries—that ever since attorneys as a profession have existed women have never been admitted to the office. In my opinion, that shows what the law is and has been, and for this reason I am of opinion that the present applicant is not entitled to insist that she has a right to be examined by the Law Society with a view to entering the profession.

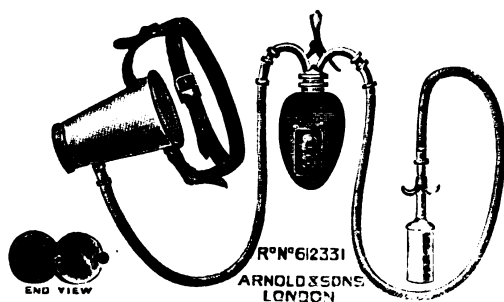

MARRIAGE.

Lord Justice Phillimore: I am of the same opinion. We are not here to say what should be the law, and I express no opinion one way or the other on that matter. Our function is to declare the law, and our first function is to declare the common law of the country. And we declare that common law according to what we ascertain to be the received inveterate usage of the country. There is no instance since solicitors became a profession of a woman being admitted, or of it being considered possible that she could be admitted. Until solicitors became a profession I apprehend the only representative or law agent of a litigant in the Court of Chancery was one of the sixty Chancery clerks, and it is obvious from the statute quoted that they were always men. Coke's view was that women could not be solicitors, and he is a witness of the highest rank. There is no evidence the other way at all. All the evidence teaches us there is an inveterate usage to the effect that this is a profession which has not been hitherto open to women, and the same arguments which could be applied to destroying that evidence might equally well be applied to the claims for the Parliamentary or municipal franchise. I do not say this is an office unsuitable to women, but it has never been in the view of the Courts suitable to women.

The cases as to parochial offices may stand on their own merits. They have no bearing upon this case. A difficulty at once arises if a woman is to be admitted, because it is clear that married women, not having an absolute liberty to enter into binding contracts personally, would be unfitted either for entering into articles, or for contracting for their clients. That, of course, does not apply to single women; but every woman can be married at some time, and it would be a serious inconvenience if in the middle of her articles, or while conducting a piece of litigation, she was suddenly to be disqualified from contracting by reason of her marriage. Construing the more recent statutes in the light of previous legislation and of the common law, I come to the conclusion that there is nothing in them to show that the Legislature intended to open this profession to women.

The appeal was accordingly dismissed, with costs.—*The Daily Telegraph*.

SCOTT'S IMPROVED DOG CHLOROFORM INHALER (REGISTERED).

Messrs. Arnold & Sons have made at my suggestion an Inhaler which seems to me more effective in operation than any other. It is a combination of other ideas together with certain improvements. The "mask" and tube is of metal, therefore aseptic and suitable for all climates. The mask has perforations at its extremity, and a valve which regulates the amount of air admitted. It is simple in use and remarkably safe—a toy dog 4lb. can be kept under for any length of time necessary (one has been for over two hours) by gradually opening the valve.

A toy 4lb. to a terrier 30lb. can be conveniently chloroformed with this one size, using from one to four drams of chloroform according to size of the dog, and length of time required.

E. H. SCOTT, M.R.C.V.S.

Nov. 27.

A "Cattle Dentist" Fined.

At Cocker-mouth Police Court on Monday, Thomas Gill, "cattle dentist," was fined £2 for obtaining 4s. from Mr. Wilson, solicitor, of Cocker-mouth, by false pretences. The defendant went to Mr. Wilson's farm at Routenbeck, Cocker-mouth, and told the bailiff that he was a "Government" cattle dentist, and insisted on inspecting the cattle. He pretended that he had drawn four teeth, which he had produced, from certain animals, and he charged the bailiff a fee of 4s. It was subsequently found that no teeth had been extracted.

The defendant's excuse was that he was tipsy. He had acted as a "cattle dentist" for 30 years. Superintendent Illingworth said that it was not an isolated case on the part of the defendant.

Serum Treatment of Swine Fever.

Mr. Runciman, M.P., President of the Board of Agriculture, was the principal guest at the dinner of the Central and Associated Chambers of Agriculture and the Farmers' Club, held at the Criterion Restaurant, Piccadilly Circus, in the course of his reply to the toast "Success to Agriculture," said, "The sum now spent in agricultural research was far greater than ever it had been in the history of the country. He hoped that work done in a great research institution of Imperial dimensions, financed out of national funds, which he believed would be organised before long, would enable them to cope with the greatest enemy of the farmer—the ravages of disease. He regretted that the restrictions in regard to swine fever had done little more than to check the spread of the disease. Experiments in Holland, and Hungary, and in the United States had not afforded conclusive proof of the efficacy of the serum treatment. The Board of Agriculture had, therefore, recently decided to undertake experiments in the treatment on selected affected farms, in the hope of arriving at some conclusion as to the efficacy of the treatment. We had less swine fever than was to be found in most civilised countries, and as to other animal diseases we had a record which every other civilised country envied."—*The Times*.

The Dog's Gamut.

A veterinary surgeon was summoned at Wimbledon Petty Sessions last month for keeping noisy dogs. Several witnesses stated that they had to change their sleeping rooms because of the noise, and one woman said that a dog went from the "pitch C to E." Another woman admitted that her husband went through the scales every morning at his bath. Judgment was adjourned for a month because of the serious effect an immediate decision might have upon the defendant, who depended upon veterinary surgery for his living.

Personal.

Mr. J. RUSSELL GREIG who since obtaining the diploma has held the appointment of bacteriologist in the veterinary department of the City of Glasgow, and Mr. C. F. Shawcross, have received appointments under the Board of Agriculture and Fisheries. Both were students of the Royal Dick College.

OBITUARY

JOHN A. THOMPSON, F.R.C.V.S., J.P., Lurgan, Ireland. Graduated, Edin: (Dick), April, 1881, F. April, 1890.

Mr. Thompson died at his residence on Tuesday, 9th Dec. Interred at New Cemetery, Lurgan, on Dec. 11.

ANDREW WATERSTON, M.R.C.V.S., Beith, Ayrshire.

Glas: Dec., 1873.

Death occurred on Dec. 4th, at the Victoria Infirmary from fracture of the base of the skull. Aged 60 years.

ANDREW MCGREGOR, M.R.C.V.S., Crieff, Perthshire.

New, Edin: May, 1890.

Death took place on Dec. 9th, at the age of 58 years, from cerebral tumour.

WILLIAM WILSON, F.R.C.V.S., Great Berkhamsted.

Vice-President of Council, 1888-9.

Lond: April, 1859, F. June, 1885.

A wide circle of friends will learn with regret the news of the death of Mr. William Wilson, F.R.C.V.S., which occurred on Wednesday, Dec. 4th, at the age of 82 years. Mr. Wilson had not enjoyed the best of health for some time, but until quite recently took his accustomed walks and showed deep interest in all that concerned Berkhamsted. He was one of the oldest townsmen, and as a veterinary surgeon he had been established at Berkhamsted over 50 years. On Saturday, Nov. 29th, he celebrated his 82nd birthday, and just twelve months ago the death of his wife was a sad blow to him. He leaves four sons, who all follow the profession of their father, and two daughters. As Inspector under the Diseases of Animals Act in this part of the county, and similar offices under the local authority, Mr. Wilson was prevented from taking a prominent part in local administration, but he did all he could to promote the welfare and prosperity of the town

and neighbourhood, which he dearly loved. For many years he was the esteemed chairman and treasurer of the Town Hall Committee, and was the oldest member of that body. He was a member of the local lodge of Freemasons and an honorary member of the Ancient Order of Oddfellows (Castle Lodge). These are but few of his many associations, for he was in former years connected with most of the public work of the town; in the restoration of the Parish Church he was deeply interested. His genial disposition and conversational gifts made him a firm favourite with all he came in contact. He was always ready and willing to work for what he considered was the betterment of the town, and although outspoken he always commanded respect. The funeral took place on Saturday last.—*The Gazette* (Berkhamsted).

EQUINE MANGE—DISINFECTION.

Sir,

At the meeting of the Midland Counties Association, when Mr. Pillers read a paper on the above subject, a speaker suggested boiling the harness. May I mention a simpler means of disinfection.

Three years ago I was called to a farm on which the horses had for a very long period been subject to attacks of mange, the disease disappearing after the animals were treated with oily dressings, to break out afresh at longer or shorter intervals, and this in spite of vigorous cleaning of the horses and thorough disinfection of the stables. The harness was suspected as a cause, and its treatment in the method about to be described has proved quite successful. No case has occurred on the farm since its adoption.

An outhouse of suitable size was selected, and a ceiling made to it of flooring boards. This ceiling and the sides of the building were covered with large sheets of brown paper, pasted on. Every Saturday night all the harness—there were twelve horses—was bundled into this house, into which also were placed three of the lamps used about here to generate sulphurous anhydride for fumigation of green-houses. As soon as the lamps were lighted the door was closed, and brown paper pasted over it. The lamps were allowed to burn out, and the door was not opened until Monday morning; this was done for six successive weeks.

The lamps consist of three parts—a tin saucer to hold the sulphur, a tin plate with a hole cut in it into which the saucer is seated, and a tin spirit lamp. The plate, with its saucer, rests on two bricks, and the lamp is placed under it. The whole apparatus costs 1s., and can be obtained from Mr. Woollard, ironmonger, Waltham Cross, N.

I should like to add that in winter it is cruel to keep clipped horses, dressed with oil, uncovered. Half an armful of good wheat straw placed longways on the back, and kept on with a couple of strawbands, gives comfort.—Yours, etc.,

W. R. DAVIS.

REBATE ON PETROL.

Sir,

Now that so many members of the profession find it necessary to use motor-cars in their work, could not a determined effort be made to get the same rebate as allowed to the medical profession?

The work entailed by the Tuberculosis Order, etc., should surely be sufficient reason for the Government to help us, and as Sir Sidney Oliver appears to be taking a kindly interest in our work, perhaps a strong deputation or petition from the Council or National Association might have the desired effect, and if a few influential members would take this matter up, the profession in general would be grateful to them. Personally, I got our M.P. to act in the matter some time ago, but the Chancellor refused then to consider the matter further.

We are doing a national service at very moderate remuneration, and if this important subject was to be taken up strongly now, it might be the means of considerable financial help to us.—Yours faithfully,

PRACTITIONER.

VOL. XXVI.

THE DIPLOMA IN VETERINARY STATE MEDICINE AND THE FELLOWSHIP DEGREE.

At the next Council meeting, the Draft of the new Supplementary Charter will be considered and, with or without some modifications of detail, will probably be finally adopted. It contains provisions for the new Diploma in Veterinary State Medicine or "Public Health Diploma," and the new regulations for the Fellowship Degree will only come into force if the Charter is obtained.

The syllabus for the Public Health Diploma is comprehensive, and includes every subject of import to the veterinary sanitarian. But the regulations as to qualification are vague, and at least appear open to criticism. A candidate, after obtaining the M.R.C.V.S. degree, must spend at least "six months practical instruction in meat inspection, hygiene of byres, stables, and markets, under veterinary inspectors or teachers recognised for that purpose by the R.C.V.S.," and a further period of six months' attendance at approved courses of instruction at an affiliated school.

The first point here is—what is meant by this first six months' instruction under a specially recognised teacher or inspector? Would the same period spent in salaried junior employment in the veterinary sanitary service satisfy the Council?—or does the clause really mean that certain inspectors are to be empowered to conduct classes for practical instruction which every candidate must attend at his own expense? This point needs clearing up, and there is another that should be emphasised. The second six months must be spent in study at an affiliated school; and this—even without the possibilities of the first six months—means a serious outlay in time and money. There are men now in junior posts in the public service, and others in private practice whose thoughts are turning the same way, to whom such an outlay would be impossible. These men are working to fit themselves for the service, and would succeed under the old conditions, but they cannot hope to do so under the new ones. When the Diploma is established, it will soon be practically impossible to obtain a good public appointment without it. Some provision could surely be made for men who are already approaching its standard of knowledge, but who cannot comply with its regulations.

It is not clear from what source the examiners are likely to be drawn; and the Draft Charter contains no provision for conferring the Diploma without examination. This omission is singular, for we have many men already in the public service whom it would be absurd to either examine or expect to attend classes. The scheme looks a good one so far as new graduates who intend to take up

public health work are concerned; but these are not the only class deserving of consideration.

No one would suggest that every member now doing public health work should either receive the diploma without examination, or be admitted to examination without further training. But some certainly ought to be admitted without examination, and, for a year at least, there should be more elasticity than is apparent in the qualifying regulations. If not, some good men will be shut out from the diploma altogether.

The new Fellowship examination will be far more specialised than the present one. Candidates may elect to be examined in any one of nine branches, viz., anatomy (including surgical anatomy), physiology, pathology (including bacteriology and protozoology), helminthology and entomology, pharmacology, and toxicology, medicine, tropical medicine, surgery, and sanitary science and administration. A thesis and its defence will form the main examination; and though the examiners may add a practical or a written examination, they will be confined to the special branch chosen by the candidate. It will no longer be necessary for a pathologist or sanitarian to pass a written examination in medicine and surgery, or for a clinician to do likewise in bacteriology, as is the case at present. These numerous branches will necessitate a large staff of examiners, some of whom will have very little to do, for some of the subjects will attract very few candidates. It may, too, be difficult to fill some of the examinerships satisfactorily without going outside the profession. The men most in touch with veterinary tropical medicine chiefly reside abroad, and physiologists and toxicologists have always been rare within our own ranks. We believe that the regulations are being altered with quite the right aims. The increased specialisation of the Fellowship degree must greatly enhance its value; and the inclusion of medicine and surgery as special branches will leave it always as accessible to the practising clinician as to any other man.

Lastly, it is important to note that, even in public health, the Fellowship degree will still remain our premier one. The Fellowship examination in sanitary science and administration will be open only to holders of the Public Health diploma. The veterinary sanitarian of the future, after first qualifying as a member, will take the Public Health diploma as an indispensable step towards a good appointment. Afterwards, if ambitious, he may take the Fellowship degree in sanitary science as a special mark of distinction. Some men may also take a B.Sc., but it seems quite possible that the new Fellowship degree may supersede those from Universities.

AN ABDOMINAL LESION.

Subject.—A valuable Shire mare, five years old.

History.—The mare had been turned out all the summer, and on the night of the 3rd-4th inst. had strayed into a field containing some stacks of barley ready for threshing. She had apparently eaten her fill, and on the morning of 5th began to show some slight uneasiness. The owner administered two bottles of Gaseous fluid, and, according to him, temporary relief resulted. Attacks of pain became more insistent, however, and at 8 p.m. on the 5th I was summoned.

Symptoms and Treatment.—Temperature 104.8 F. Pulse 90, frequent, small and tense. Visible membranes injected. The mucous membrane of the mouth was inflamed, and some vesicles were present. This condition I attributed to the above-mentioned Gaseous fluid, the more so as the owner reluctantly confessed that the mare had rubbed her mouth on the manger with extreme vigour after the administration of this "marvellous vegetable remedy." The face was "drawn," and there was frequent turning up of the lips. Pain was spasmodic in character, and intense during the spasms, the favourite position being on the side with all four legs drawn close to the body. Body was covered with patchy sweat. Borborygmus was barely noticeable. The rectum was dilated and empty. No faeces had been passed since the previous evening. My diagnosis was "wait and see," and prognosis guarded—very.

I administered 1½ pints of linseed oil, and digalen hypodermically, also two chloral hydrate balls, each containing half an ounce of the drug.

5th, 11.30 p.m.—Animal has had some relief, but within the last hour pain has been constant. Pulse is not so good, probably digalen has been too depressing.

Administered liq. strych. hcl. ʒii. and digalen ʒii. hypodermically. Hot enemata seem to give relief, so decide to stick to them for a while.

From now till 4 a.m. administered hot enemata every half hour (three gallons), and notice that they are being held longer as time goes on.

At 3.30 a.m., on rectal exploration discover a small piece of faeces in the rectum. On withdrawal, this proved to be a perfect cast of the bowel containing hardened faeces. The cast was in the form of a tube about 4½ inches in length, fairly tough, and black in colour. Following the removal of this cast, about a pint of liquid faeces, apparently mixed with disintegrated blood, came away.

6th, 6.30 a.m. Violent pain ceased. In the meantime a small quantity of blood-stained faeces has been passed. Pulse is wretched in tone, and a tenseness of the abdominal walls together with an agonised expression on the face point to peritonitis now being present.

Treatment. Nux vomica ʒss., digitalis ʒss. every three hours. I also managed to visit the case three times during the day and gave copious hot enemata.

7th. Mare much improved. Abdominal wall less tense. Temperature 102, pulse 50. Treatment continued, but powders given every four hours.

8th. Mare normal, and feeding as much as she is allowed. All treatment stopped.

9th. Mare still normal, and of course one has to finish visiting.

Remarks. The only interest about this case to me is in the fact that it is the first time that I have seen a cast of the bowel passed per rectum in the horse.

I have seen the phenomenon on various occasions in cattle under the conditions in which the owner in Ireland tells you "Sure an' she passed a lump of a tree" (this from the gnarled appearance of the wrinkled mucous membrane); and also some shreds of membrane passed by horses, but never a complete and perfect cast. I suppose it was a case of intussusception.

R. F. STIRLING, F.R.C.V.S.

Lancaster.

RUPTURE OF UTERUS IN A COW—A WARNING.

Some four weeks ago I was called to a five-year-old cow, which was said to have been off her feed for some days and constipated. The owner had administered certain potions, including the ubiquitous red drench. She was due to calve in a week's time.

The temperature was subnormal, the pulse weak. There was extreme dullness and enlargement of the abdomen. The patient emitted a low moan every few seconds.

On proceeding to examine the uterus, I found the os fully dilated, and a little further, on the left side towards the floor of the womb, a rupture large enough to admit a calf's head. I passed my hand through and felt the bowels and bladder. The foetal membranes were already ruptured, and the calf had apparently been dead some days.

I explained the condition to the owner, and assured him, with no little confidence, that the cow would die. We decided to deliver the calf, and as there was very little contraction in the ruptured uterus, we experienced some difficulty. And I went my way.

A week later an old professional friend spent an evening with me, and I mentioned the case to him. "Take care you don't get a rude shock" he said, "I had a similar case last year, and prognosticated as you did, but the cow recovered. There was this difference, that in my case the rupture was in the roof, and in yours towards the floor of the uterus." This made me curious to know the fate of my cow, which was a good many miles away.

A few days ago I met my client. He is, fortunately, brimful of human nature. He wore a roguish smile and whispered "would you advise me to fatten that cow or keep her for breeding again? She never looked back."

L. W. WYNN LLOYD,

Carmarvon.

ANOTHER UNEXPLAINED LAMENESS.

Apropos of Mr. Howard's article on "A puzzle in lameness," the following case may be of interest.

A mare of my own, a four-year-old half-bred Irish hunter, frequently goes dead lame at the walk, in the off hind leg. This is especially marked when the mare is in any way excited, as for instance when she is out with hounds. In fact it becomes a nuisance, as I am so often asked if I know that my mare is lame behind. At the trot she is perfectly sound, and when not excited, and walking with a loose rein, she is, as a rule, sound. It is not a peculiarity of action, it is a distinct lameness, the stride being shortened by one half that of the near hind. When led she invariably walks quite normally. The interest of such cases is principally from the aspect of veterinary jurisprudence. Is such an animal technically sound?

In the case of Mr. Howard's patient the animal would be unsound, as there would be inability for work; but there is no such inability in the case of my mare. The drawback would be the unpleasantness of riding an animal thought to be lame by the average observer. The cause would appear to be undoubtedly of nervous origin, not to be defined more precisely than a functional disorganisation—a sort of hysteria. I should like an opinion from a jurisprudence point of view.

WAKEFIELD RAINEY.

ABSTRACTS FROM FOREIGN JOURNALS.

POISONING BY TOBACCO JUICE IN CATTLE.

Giovanoli has published (*Schweizer Archiv.*) an article which proves that the employment of tobacco juice for the destruction of cutaneous parasites in cattle is far from being inoffensive. His first observation is the following. About 10 o'clock in the morning four cattle—one two-year-old ox, one three-year-old cow, and two heifers aged eight and thirteen months respectively—were washed with a solution of tobacco juice to rid them of lice. Two hours later the two heifers were found in a very critical condition. The breathing was accelerated and noisy, the whole body showed muscular trembling, the head and neck executed irregular movements, and the eyes were fixed. Both heifers stamped constantly with the hind feet, and one discharged softened faecal matter. The mouth could only be opened with great difficulty. Three hours after this, both the heifers were dead; while the two other animals which had been dressed with the same solution showed no abnormal symptoms.

The post-mortem examination of the heifers was carried out quickly. All the visible mucous membranes were markedly injected, and the pupils were dilated. The internal organs were normal, except that the lungs were engorged with blood and showed a blackish-red colouration. The blood was fluid, and had a black tar-like colour; when exposed to the air it rapidly became red.

The author's second observation is as follows. He was called to a two-year-old ox, which had been washed with a solution of tobacco juice to rid it of lice, and found that it had been thought necessary to slaughter the animal before his arrival. The ox had begun to tremble and sweat, an alarming tympany had appeared, and progression had become staggering to such a degree that the animal threatened to fall at every step. Two cows which had been treated with tobacco juice at the same time, but a little less energetically, showed somewhat similar symptoms. Four hours after having been washed with the solution they showed embarrassed respiration, weak and frequent pulse, cold horns, slight tympany, and profuse sweating. These symptoms, however, never became alarming in the two cows, while the ox had to be slaughtered.

The post-mortem examination of the ox revealed no lesions except those of pulmonary tuberculosis. No internal organ and no muscle gave forth an odour of tobacco. As a cooking test of a piece of muscle revealed no special odour, the flesh was declared fit for consumption. The tobacco juice used had come from a cigar manufactory, and had been mixed in water in the proportion of 6 per cent. The solution had been rubbed upon the back, and upon the sides of the neck and shoulders.—(*Annales de Méd. Vét.*)

ECHINOCOCCI IN HEART MUSCLE.

G. Giovanoli, of Soglio records (*Schweizer Archiv.*) three cases of this occurrence, all very similar.

The first was a working ox which, while drawing a heavy load along a difficult road, suddenly showed great difficulty of breathing, trembled all over, and fell dead. Post-mortem, a whitish convexity was found in the middle of the left wall of the heart. This proved to be an echinococcus cyst containing about 4½ oz. of fluid.

Another working ox, which died while ploughing, had an echinococcus cyst the size of a hen's egg, in the left wall of the heart, projecting inwards into the ventricle.

The last case was a cow, which died suddenly at grass. Numerous echinococcus cysts were found in this animal's lung, and also one in the right wall of the heart.—(*Münchener Tier. Woch.*)

W. R. C.

THE PERSISTENCE OF THE BACILLUS OF INFECTIOUS ABORTION IN THE TISSUES OF ANIMALS.—By W. E. COTTON, D.V.M., Bureau of Animal Industry Experiment Station, Bethesda, Md. Presented to the 50th annual meeting of the American V.M.A. in New York, Sept., 1913. [Abstract].

The work from which the data was obtained was done at the Experiment Station of the Federal Bureau of Animal Industry, at Bethesda, Md., under the direction of Dr. E. C. Schroeder, Superintendent, to whose guidance and help I am greatly indebted both in making the observations and in preparing the data presented.

At the forty-eighth annual meeting of this Association Dr. Schroeder and I presented a paper (1) in which we described an organism that we had found to be

eliminated with the milk of a considerable number of apparently healthy cows; that it was of common occurrence in market milk; and that it produced lesions in guinea pigs which somewhat resembled those produced by the tubercle bacillus. At that time we had failed to identify the organism, which we now know to be that of infectious abortion.

To gain some information as to the constancy with which aborting cows eliminate this organism with their milk, and the length of time they persist in doing so, as well as that during which the genital tract remains infected after an abortion, careful watch was kept over all the cows at the Experiment Station; infectious abortion being present among them and slowly infecting the entire herd.

The presence of the abortion bacillus in milk, as well as in other materials, was determined by the inoculation of guinea-pigs, in which, as we have pointed out, it produces characteristic lesions. We have also made cultures from many of the guinea-pigs showing these lesions, and recovered the bacillus from them. In making tests with guinea-pigs, two were inoculated in each instance. In making the milk tests, each guinea-pig received from 4 to 6 cubic centimetres of whole milk intra-abdominally; in tests of other material the inoculations were usually made subcutaneously. It should be said of the guinea-pigs used in making these tests, as well for all those used for any purpose at the Experiment Station, that of the several thousand that we have autopsied since this investigation has been in progress, we have yet to find lesions of abortion disease in a single guinea-pig in which we had not a right to expect to find it. The work is thoroughly checked up by very many tests of milk and other materials, in which guinea-pigs were used, both in this and in other investigations.

The reproductive organs of a bull that had been used to serve some of the aborting cows, and the testicles of two bull calves, one of which had been fed and the other injected with cultures of the abortion bacillus, were tested for the presence of this bacillus, but it was not found to be present in any of them, though portions of practically all of the reproductive organs of the adult bull were used in making the tests. We were led to make the above tests because a large proportion of male guinea-pigs which are infected with abortion bacilli, develop grave lesions of the testicles and epididymides; and we have found that these males infect females with which they copulate. We also found the lesions to be present in the epididymis of a rabbit that had received an intravenous injection of the abortion bacillus a number of weeks previously. We thought it possible that the organism might remain in the testicles and epididymides of the male bovine animals without producing visible lesions, as it does in the udder of the female. So far as our investigations have gone, it seems that the bull does not harbour the bacillus in this manner, but they have not yet progressed far enough to be conclusive.

In our milk tests, we found that of the cows at the Experiment Station nineteen have records of having aborted, of having eliminated the bacillus with their milk, or both. It will be necessary to give the records of a few of these in detail, because of some peculiar conditions in each, and in order to show the regularity with which the organism is eliminated from some animals.

Cow 637 is perhaps of the greatest interest, since it was she in which we first demonstrated that the bacillus was eliminated from the udder, and hence, we have a longer record of her than the other animals. She was purchased from the Maryland State Experiment Station, and according to its records aborted on Sept. 21, 1907, in the seventh month of pregnancy. She had aborted once since she has been at Bethesda, on July 25,

1911, in the fifth month of pregnancy, the abortion bacillus being found in the fetus.

The first test of her milk, made on February 20, 1909, was positive. Later tests were made as follows: Nine in 1909, four in 1910, fourteen in 1911, thirteen in 1912, and three in 1913: 44 including the first. With the exception of two, made two and three months after abortion, all were positive. She has thus eliminated the abortion bacillus almost continuously for at least 4½ years; and if counted from the time she is reported by the Maryland State Experiment Station to have aborted, which, judging by our experience with other cows, is the probable time at which the milk became infected, would make five years and eight months as the probable time that the organism has persisted in her udder. Her milk when last tested was just as virulent for guinea-pigs as it ever was, and we have no reason to believe but that the bacillus will persist in her udder permanently.

She produced a calf fifteen months after the last abortion occurred; tests made of the placenta showed that the bacillus was absent.

A remarkable fact in connection with this cow, as well as with all cows that carry the abortion bacillus in their udders and yet abort a second time, is that the bacillus in the udder did not induce the production of sufficient anti-bodies to prevent the invasion of the uterus and consequent abortion. It is possible that abortion may have been caused by infection with another strain more virulent than the one in her udder, but this idea does not seem to be in harmony with the laws of immunity. An attenuated strain of an organism ought to induce some immunity against a more virulent one, and besides in this instance, as nearly as we could determine by cultural methods and guinea-pig tests, the organism from the udder and that from the fetus were identical.

Cow 479 is also of interest in this connection, since she has aborted twice, and because of the appearance of the abortion bacillus in the placenta discharged at a normal parturition, the third such since the last abortion, four years and five months after the abortion occurred. This seems to indicate that abortion bacilli sometimes appear in the uterus years after an abortion, but either because of the lateness of their appearance, or the high resistance of the organ, are prevented from damaging the placenta to such a degree as to cause abortion.

We have tested the placenta of two other cows, each passed at the termination of the normal pregnancy following an abortion, and that from a normal birth in a cow that never aborted, but which harboured the abortion bacillus in her udder, all with negative results. Just how frequently the condition observed in cow 479 occurs, I am unable to say, but from the fact that one such case was found out of four animals tested, would indicate that it is not uncommon, and hence it follows, that if aborting cows are permitted to enter healthy herds, that the discharges from the uterus following a subsequent normal parturition must be regarded with suspicion.

While the condition found in this cow may be attributed to a new infection, it seems much more probable that it was due to the migration of the bacillus from the udder to the active uterus. We have found the supramammary glands of cows to be infected, showing that the bacilli were travelling towards the blood stream, and once in that, it is not difficult to conceive of them reaching the pregnant uterus, where, finding a favourable soil in the embryonic tissue which it contains, they multiply and set up disease. In some respects the abortion bacillus behaves much like the tubercle bacillus, which may remain latent at some point in the body, till conditions arise that make it possible for it to migrate from the original focus to some organ, the resis-

tence of which is below normal, and set up disease. The abortion bacillus, so far as we know, is able to develop only in the pregnant uterus and the udder; the former being the seat of its greater activity, comparable to the weakened organ in tuberculosis, and the udder the seat of the latent focus from which it is infected.

Tests of this cow's milk showed it to be infected when first tested, November 21, 1910, and that it was still infected May 5, 1913, twenty-nine months later. Sixteen tests made in 1912, and three in 1913, showed the bacillus to be present in all but two. She has, therefore, eliminated the abortion bacillus from her udder, to our knowledge, for twenty-nine months, and for the last sixteen months, at least, almost continuously. As her second abortion occurred four years and seven months previous to the last milk test, the organism must certainly have persisted since that time, and in all probability since the time of her first abortion, or for a period of five years and seven months. Separate tests made of milk from each quarter of her udder on May 5, 1913, showed that all quarters of this organ were infected.

Cow 751 has aborted twice, in her second and third pregnancies, on December 19, 1911, and on February 11, 1913. Abortion bacilli were found in placenta at first abortion, but not in fetus, and in both placenta and fetus at the last one. Repeated tests of vaginal scrapings proved that the bacillus was eliminated through this channel up to and including the thirteenth day following abortion. Several subsequent tests were negative. In one other animal, the vaginal scrapings were found to be infectious forty-six days after abortion. M'Fadyean and Stockman (2) found that the bacillus had disappeared from the uterus of a cow killed one month after aborting.

One observation made in connection with this cow proved that uterine discharges containing abortion bacilli can be exposed to the weather for a considerable time and the bacilli remain alive. A large quantity, perhaps 250 c.c., of clear mucous containing islands of chocolate coloured flocculent material was passed from her uterus on the eighth day after abortion. It was allowed to remain on the ground, exposed to the sun for ten days, the weather remaining clear for the most part and warm for the season of the year (February), by which time it had dried into a tough leather-like mass, which on being tested by guinea-pig inoculations, was found to contain living abortion bacilli. Unfortunately the material left after the tenth day of exposure was accidentally destroyed, so that we were not able to determine the maximum length of time that the bacillus will remain alive under these conditions.

This cow's milk was found to be infected at the first test made, nine days after her first abortion, and was still found to be infected when last tested, February 15, 1913, thirteen and one-half months later. Twenty-nine tests were made in 1912, and four, in addition to the last one, in 1913. Of all tests made, thirty-one were positive and four negative. She has, therefore, already eliminated the abortion bacillus almost continuously with her milk for thirteen and one-half months.

We have found the abortion bacillus to make its appearance in the milk of three cows before abortion occurred, and in one of these even before the beginning of the pregnancy which was terminated by an abortion. The one in which this occurred, No. 621, gave birth to a calf at term, on December 20, 1911; tests of milk made eight, thirteen, sixteen, and twenty days after, were all negative. The next one, however, made sixty-five days after the birth of the calf, was positive, as were also two others, made six and fifteen days after this. She was served fifty-two days after the bacillus was first found in her milk, and aborted on November 4, 1912, two hundred and fifty-five days after it was found.

Tests of her milk made in the third, fourth, fifth, and sixth months of her pregnancy were all positive, as were also daily tests made the first week after abortion, and six others made at irregular intervals, the last of which was made on May 26, 1913. She has then continuously eliminated the bacillus with her milk beginning nearly two months before the beginning of a pregnancy which was terminated by an abortion, and has continued to do so with great regularity up to the last time her milk was tested, a period of fifteen months.

The record of this animal shows that a cow's milk may become infected before conception, and seems to indicate that instead of the presence of the bacillus inducing immunity when introduced at this time, as has been supposed, it is stored in the udder till the uterus by becoming active furnishes a soil for its rapid multiplication. It seems, therefore, that any system of immunisation that depends on the subcutaneous or intravenous injections of living cultures of this organism before conception is unsafe; for it would not only probably make most of the animals so treated carriers, and contaminate their milk, but would, at least occasionally, set up active disease. I do not want to be understood as opposed to efforts to evolve methods for immunisation, and I hope that something can be done in this direction, but immunity in this disease seems to be such an uncertain quantity, and the possibilities for evil in this organism, not only for animals but for man as well, so great that we had better go slowly.

Three cows, Nos. 171, 503, and 638, have never aborted, yet have continued to harbor the abortion bacillus in their udders. They are somewhat like those cases in man which continue to harbor the typhoid bacillus though they have never manifested symptoms of the disease. For some reason, the uteri of these cows seem to have either inherited or acquired sufficient resistance to prevent the organism from developing there, at least to such an extent as to produce abortion, though it continues to persist and to multiply in their udders; sufficient general immunity not being produced to drive it from this stronghold. Has the abortion bacillus, present in the udders of these cows, induced immunity in their uteri which it failed to do in cows 637 and 621, or must we regard these organs as naturally immune in these cows, or is there some other reason?

Mohler and Traum (3), Larson (4) and others have shown that some cows react to the complement fixation test, but do not abort. No doubt many such are of the kind just described, and that the reaction depends on the actual presence of the abortion bacillus. In other words, a cow reacting to this test probably has the organism either in her udder or uterus.

This type of carrier is a dangerous one, because unsuspected, and can only be found by making milk tests, or one of the serologic tests. Some simple reliable test is urgently needed, and it is to be hoped that such a one will be perfected in the near future.

Nine other cows which have aborted in from the fifth to the eighth month of their pregnancies, have already been eliminating the abortion bacillus, some continuously, some intermittently, for periods varying from two and one-half to twenty-nine months, and if kept under observation longer, I have no doubt will continue to do so for months and years to come, for in none of them is there evidence of the infection dying out.

One cow, No. 758, that aborted a fetus in which the abortion bacillus was demonstrated, has given negative results to all milk tests thus far made. She is certainly the exception that proves the rule. Her abortion occurred in the seventh month of her second pregnancy. It is possible that even in this cow more frequent tests would have revealed the bacillus in her milk, for we have one other cow the milk of which shows infection only at long intervals.

SUMMARY.

Of the nineteen cows under discussion, eighteen have eliminated the abortion bacillus with their milk, sixteen are known to have aborted, three have not aborted but eliminated the bacillus with their milk, and one aborted, but we were unable to find that her milk was infected through abortion bacilli were found in the fetus.

One cow is known to have been eliminating the bacillus with her milk practically continuously for four years and three months. One almost continuously for two years and five months, and the organism must have persisted in her body for at least four years and seven months; one almost continuously for thirteen and one-half months; one continuously for fifteen months; one intermittently for eleven months; one almost continuously for eleven months; one continuously for six and one-half months, then she became dry, and the bacillus was still present in her udder tissue thirteen and one-half months later; one intermittently for over two years; one almost continuously for over three years and four months, and nine continuously or intermittently for from two and one-half to twenty-nine months.

Since different strains of this organism seem to possess widely different cultural characteristics as well as degrees of virulence, it is possible that animals infected with other strains than those with which we have worked may give different results. Fabyan (5), however, found out of a herd of twelve cows two which eliminated the organism in their milk. One of these had aborted a week before in the eighth month of pregnancy and the other gave birth to a normal calf eleven months before. Another cow aborting at the third month was negative. These results are confirmatory of our observations.

PERSISTENCE IN SMALL EXPERIMENT ANIMALS.

Just a word as to the persistence of the organism in the tissues of guinea-pigs, rabbits and mice. We have recovered the bacillus from the spleens of guinea-pigs showing lesions, seventy-one and seventy-seven weeks after infection. Tests made of five other guinea-pigs which had been injected with the abortion bacillus twenty-one to twenty-seven months previously, and which showed only very slight lesions on autopsy, were negative.

The apparently normal spleen and liver of a rabbit, which had received three intravenous injections of abortion bacilli, were found to contain the organism 131 days, or nearly nineteen weeks after the last injection was made. The organism was found to be present in the spleen of three white mice, in which it produced lesions 103 days, or fifteen weeks after inoculation.

Fabyan (6) reports finding the organism to be present for sixty-seven weeks in guinea-pigs, ten weeks in the spleen of a rabbit, and for considerable periods in the tissues of monkeys, rats, mice, and pigeons after injection with abortion bacilli; though with the exception of the guinea-pigs and mice without producing lesions.

CONCLUSIONS.

1. The bacillus of infectious abortion, or at least the strains with which the Experiment Station has worked, may, and in most cases does, persist in the udders of cows that have aborted for years and possibly for the balance of their lives; and during this time is eliminated more or less continuously with their milk.

2. It may make its appearance in the milk months before abortion occurs, even before a conception that is terminated by an abortion.

3. It may be eliminated for years from the udders of cows that never aborted.

4. It may persist in the genital tract for as much as

forty-six days after an abortion; and the bacilli contained in uterine discharge may resist the action of sun and weather for at least ten days.

5. It may appear in the placenta of a normal pregnancy subsequent to abortion.

6. It may persist in the spleens of inoculated guinea-pigs in which there are lesions for seventy-seven weeks, and in the spleens of inoculated rabbits for nineteen weeks, without producing lesions.

It is to be hoped that we will soon know more about this strange organism. Its variable character and the seeming existence of many strains, no doubt, are responsible for much of the confusion in the past, and the fact that it seems to prefer primitive embryonic tissue as a soil, suggests that it may be an organism not yet fully adapted to differentiated tissue, and ready, by a process of mutation, to assume additional pathogenic significance in several species of animals. In other words it may be the possible parent germ of some future pathological factor.

American Veterinary Review.

YORKSHIRE
VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A. NORTHERN BRANCH.]

A meeting was held at the Hotel Metropole, Leeds, Oct. 31.

The SECRETARY (Mr. J. Clarkson) before the business of the meeting commenced, read a letter from Mr. J. Abson, of Sheffield, President of the Society, explaining that owing to ill-health he was unable to attend the meeting. In the absence of Mr. Abson he would call on the senior vice-president to occupy the chair for the time being.

Mr. McCARMICK, who then took the chair, said they would all be sorry to hear that Mr. Abson was unable to be present that day, and he hoped he would soon be convalescent.

On the motion of Mr. J. McKinna (Huddersfield) it was decided to send a letter to the President expressing the deep sympathy of the Society with him in his illness, and hoping that he would have a speedy recovery.

THE LATE WILLIAM HUNTING, F.R.C.V.S.

Mr. McKINNA: I am sure I shall be echoing everyone's feelings to-day when I rise to speak with reference to our late lamented friend, Mr. Hunting. I only heard of his death to-day, and I did so with deep feelings of regret. We have lost a leading light in the profession, one of our brilliant stars, looked up to and held in the highest esteem even by those who many times were in opposition to him. He was loved by the whole profession, and before starting our meeting to-day I think we might express our deepest sympathy with his family

in the great loss they have sustained, and the profession as well.

Mr. CLARKSON : I would like to second this vote of condolence. Mr. Hunting always had the Society very closely in his heart, he has always been very much attached to it, and I think we can say that we always had very great pleasure in receiving him. He has been one of our Honorary Associates for a very long time. At the time of his death the officers of the Society sent a wreath, but I shall be glad as Secretary to forward any letter you may direct.

Mr. McCARMICK : It has been moved and seconded that a letter of condolence be sent to the relatives of Mr. Hunting, and I ask you to show your sympathy in the usual manner by standing. The resolution was adopted.

Minutes. Mr. Clarkson read the minutes of the last meeting.

Correspondence. Mr. CLARKSON said he had no official correspondence to read, but he would like to send a letter of thanks to Mr. Pratt. Quite recently, in addition to his original gift, Mr. Pratt had made the Society a gift of a number of books. There were a good many books which were very valuable, and as this was in addition to the collection of shoes and pathological specimens, it came extremely nicely from Mr. Pratt.

Mr. McCARMICK : I am sure we all appreciate Mr. Pratt's kindness to the Society. I think the least we can do is to send him a letter of thanks.

It was intimated that Mr. Pratt was at that moment lying seriously ill.

Mr. F. SOMERS (Leeds) proposed a vote of thanks to Mr. Pratt, who, he said, had been a most generous, and chivalrous donor to the Society.

Mr. McKINNA, who seconded, said Mr. Pratt gave the gifts very graciously. Their sympathies would go out to him in his illness.

Mr. CLARKSON : I would suggest that we include in the letter a vote of sympathy with Mr. Pratt in his illness. He is the only foundation member of this Society now remaining. Although other men have perhaps got the credit for it, I believe that Mr. Pratt really thought out the formation of this Yorkshire Society. This is the first meeting the Society has ever held since I became Secretary that Mr. Pratt has not been able to attend or has written, and I presume from that that he is still very ill.

The Secretary was instructed to write to Mr. Pratt in accordance with the wishes of the meeting, and Mr. McCarmick then presented the balance sheet, which showed a balance in the bank of £29 14s. 6d.

On the motion of Mr. McKinna, seconded by Mr. S. Wharam, the balance sheet was adopted.

ELECTION OF OFFICERS.

Mr. W. CRAWFORD : In the absence of our President, I may be allowed to say what a good president he has been during the year. Those who were at Sheffield will remember the manner in which we were treated, and appreciate it. Next year will be a very big one, with the International Congress, and we do want a man to represent us this time. I have great pleasure in proposing that he be re-elected for another year.

Mr. J. H. GILLESPIE seconded.

Mr. McCARMICK : I have very great pleasure in rising to support that resolution. He has been an admirable President, and he has satisfied the Society in every way. [Carried].

Mr. MASON proposed that Mr. G. E. BOWMAN be elected the Senior Vice-President, and Mr. W. P. WESTON and Mr. S. E. SAMPSON as Vice-Presidents.

Mr. M. ROBINSON seconded, and the motion was adopted.

In the absence of the newly-elected senior Vice-President the chair was then taken by Mr. S. E. Sampson.

Messrs. McCARMICK (Hon. Treasurer), J. CLARKSON (Hon. Sec.), A. W. MASON and W. CRAWFORD (Auditors) and the same members of Council as before were re-elected.

New Members. The following nominations of new members were received: Messrs. VINE, Settle; THEXTON, Pontefract; and NICHOLSON, Bridlington.

Mr. CLARKSON : During the coming year Mr. Mason comes off the Council R.C.V.S. He has been a member for nearly a quarter of a century, and the Council thought that if he would consent to stand again, the Society ought to ask him to be their official nominee. I have great pleasure in nominating him.

Mr. WHARAM : I have great pleasure in seconding that Mr. Mason's work on the Council is well known, and as regards the representation of the Society, I don't think we can have a better man.

The motion was adopted, and Mr. Mason in thanking the meeting said : I thank you very much for the compliment and honour you have paid me in making me your official nominee for the Council. You know I have been your representative for a number of years, and my past services must certainly have been appreciated or you would not have nominated me to-day. For the last two years I have not perhaps been such a good attender at the Council meetings as I used to be in former days, but I do endeavour to attend these meetings if there is anything important going on. There are important questions before us at the present moment, and when there is anything particular on I will attend. Thank you very much for the compliment.

It was decided to amalgamate with the usual Societies for election purposes.

Mr. McCARMICK said it seemed that one member gave it as his excuse for non attendance that the meeting was always held on a Friday. He begged to propose that the Council take into consideration the advisability of altering the day of the meeting from a Friday to a Thursday.

Mr. McKINNA said the members present might express an opinion as to what date was most suitable for them.

Mr. SAMPSON thought they might take a poll by a show of hands, and this resulted as follows : Friday 11, Thursday 7, Monday 1.

QUITTOR.

Prof. A. GOFTON, F.R.C.V.S., Royal (Dick) College.

I would feel that some apology was necessary for introducing such a time worn subject as quitor if it were not for the fact that in so doing I am acting on the suggestion and invitation of your President.

Unanimity of opinion does not exist in regard to the use of the term quitor, in respect of the causes and methods of origin of the conditions to which it is applied, or in regard to the most appropriate line of treatment. For these reasons, and also because its treatment calls for considerable work with not infrequently disappointing results, quitor remains a subject of perennial interest. I have no new facts to place before you, I merely submit my views for your consideration and criticism. I purpose limiting my remarks to the definition of the condition, and to its method of origin.

A system of nomenclature which permits of the application of one name to two or more essentially different conditions calls for unqualified condemnation. The term quitor is deprived of any real meaning or significance if it is used without limitations, or to put it in

other words, if it is applied to several conditions presenting similar symptoms but differing essentially in cause and nature. One cannot, therefore, emphasise too strongly the desirability of attaching a definite meaning to the term.

One cannot, with any confidence, claim general agreement on more than two points in regard to what constitutes a quittor—a suppurating wound usually in the form of a sinus, and chronicity. In respect of location, there is fairly general agreement, but one feels that even here one is not on too sure ground. It is usual to describe a quittor as associated with a wound on the coronet, but that is not sufficient, because, as I hope to be able to show presently, a condition essentially the same as that which is associated with the chronic suppurating sinus in the region of the coronet may exist in the absence of a wound in that position. For this reason I prefer to describe a quittor as located within the region of the lateral cartilage. By some the term quittor is also applied to chronic suppurating wounds located on the coronet, but which are out with the region of the cartilage. In my experience it is not usual to apply the term to such conditions, since they are generally without material difficulty recognisable as dependant on conditions essentially different from those associated with the wound located in the region of the cartilage. But if it be assumed that such use of the term is common, it must be admitted that the great majority, probably not less than 90 per cent. of the chronic suppurating wounds located on the coronet and to which the term quittor is applied, are situated within the region of the cartilage.

These features are merely symptoms, and give no indication of the real nature of the conditions to which the term is applied. Careful systematic examination and investigation of all chronic suppurating wounds located in the region of the lateral cartilage of the foot will show that probably 100 per cent., certainly not less than 95 per cent. are dependant on necrosis of a portion of the lateral cartilage. This is a distinct condition, and merits the application of a term the use of which will clearly and unmistakably indicate its occurrence. If the term quittor is to remain in general use and is to possess any real significance, I would urge the adoption of the suggestion made recently by the late Mr. Hunting, that the name be applied to this condition and no other. Difficulties in the way of differential diagnosis may be urged against this restricted use of the term. But difficulties in diagnosis do not justify disregard of attempts to attain scientific exactness, or simplicity and clearness of nomenclature. Further, the difficulties which are encountered are seldom insuperable, and the cases in which the existence, or otherwise, of necrotic cartilage cannot be established by means available to every clinician constitute a very small proportion of the whole.

On the basis that quittor is to be regarded as a chronic suppurating wound dependant on necrosis of a portion of the lateral cartilage of the foot, the causes on which it depends, and the manner in which the necrosis is produced, may be considered.

Cartilage has a very limited blood supply, its vitality is low, and it appears to be very susceptible to injury. Its reparative powers rank amongst the lowest of the various body tissues, and once injured, necrosis appears to follow more readily than recovery. In the great majority of cases quittor is secondary to some septic process within the hoof, in the course of which the septic material is brought into intimate contact with the lateral cartilage, producing serious injury to, and necrosis of, a portion of it. It is well recognised that the primary injury responsible for the sepsis may be inflicted to the coronet or to the ground surface of the foot in the region of the heel. The injuries in the latter position are responsible for the majority of quit-

tors. Pus is formed beneath the horn at the heel. It is not liberated until the pus has commenced to separate the horn from the corresponding sensitive structures. It travels in the direction of least resistance, which naturally varies according to its primary location. It may be the sole, or the bar, or both, which are principally under-run. It is then extremely rare for a quittor to result. When the horny and sensitive laminae are separated, quittor is almost inevitable unless prompt and efficient measures of relief are taken. In a very short time pus will be discharged between the horn and the skin at the coronet, and its escape will relieve in some measure the pain of the condition. But the relief is only temporary. The symptoms recur with the formation of a second abscess above the original point of discharge. This abscess breaks through the skin, leaving the discharging sinus, which is the external evidence of the establishment of a quittor.

Once infection has penetrated up the wall beyond a certain point, especially when the location of the primary infection is within the region of the wing of the pedal bone, the removal of the horn from the ground surface of the foot will rarely permit the escape of the whole of the pus, or succeed in preventing its appearance at the coronet, and the formation of the secondary abscess. The anatomical arrangement of the parts makes its escape by the lower opening almost impossible unless the separated wall is completely removed.

The first necrotic areas of cartilage found in quittors which arise in this way are invariably situated along the union of the cartilage with the wing of the os pedis, and on the outer or superficial surface of the cartilage. If transverse sections of the foot be examined, it will be found that this is the only position between the ground surface of the foot and the coronet, in which pus has an opportunity of lodging. In this position a certain amount of connective tissue is interposed between the laminae on the one side, and the bone and cartilage on the other. Below this point the horny and sensitive laminae only are interposed between the bone and the horn of the wall—both unyielding structures. Above it the cartilage and the horn are equally closely approximated. Considerable resistance, therefore, exists to the passage of pus either in an upward or in a downward direction from this position, hence its tendency to accumulate. The proof that it does lodge and is retained in this position, can be obtained by any one who takes the trouble to remove the separated wall shortly before or after pus has appeared at the coronet between the skin and the horn. The result of its retention is necrosis of soft tissue and then of cartilage, changes which are not long delayed. The secondary abscess, which is the first external evidence of these necrotic changes, is formed by the further penetration of the pus in an upward direction between the coronary band and the lateral cartilage, and its accumulation in the subcutaneous tissues.

The extreme angle of the heel, where the horn of the wall is reflected to form the bar, is another position in which quittor frequently takes its origin. Here the changes are similar, but the course and symptoms are somewhat modified. If transverse sections of the foot be examined in this position the sensitive laminae alone are found interposed between the cartilage and the horn. When infection of the soft tissues occurs, pus penetrating between the sensitive laminae is brought into immediate relationship with the cartilage with results equally as damaging as in the former case, but which probably occur at an earlier period. As a consequence, quittor is an almost inevitable result of infection of the soft parts unless immediate steps are taken to release pus when it forms in this situation. If no exit for the pus is provided on the ground surface of the foot, the usual abscess appears on the coronet and the case follows the usual lines. If an opening be made at

the angle of the heel at a slightly earlier period of the case, the pus escapes, but a sinus will remain. There is, however, no lodgment of pus between the ground surface of the foot and the coronet. The insertion of a probe into the sinus will demonstrate at once that the cartilage is exposed, and if further proof that necrotic changes have taken place be required, it is furnished by the failure of the ordinary simple measures to arrest the continued discharge. Provided this lower opening is kept patent, a considerable period—it may be as long as two months—may elapse before any abscess or sinus appears on the skin above the coronet. The condition present is essentially the same as quittor with a wound on the coronet. Sooner or later, as the result of obstruction to the free escape of discharge from the lower opening or of extension of necrosis of cartilage, a secondary abscess forms on the coronet and the usual symptoms of quittor are presented.

In the case of injuries to the coronet the process is not difficult to follow. The tread or other injury may by its direct effects produce necrosis involving cartilage as well as soft tissues, or, indirectly, the same changes may take place in consequence of bacterial infection. In either case a wound or sinus is established, associated with more or less extensive necrosis of cartilage. In quittors arising from coronet injury it is not infrequent to find the necrotic process confined to the inner or deep face of the cartilage. The position of the primary injury affords the explanation of this in most cases. Given a deep-seated abscess on the coronet extending down on to the inner side of the cartilage, the facility with which pus may penetrate along the deep face of the cartilage is easily appreciated on an examination of the extremely loose connective tissue which lies between it and the firmer structures which form the great mass of material interposed between the inner and outer cartilages of the foot at the heel. It is a matter of common observation in these cases that the necrotic cartilage is usually situated at the union of cartilage and bone, and it is in this position that the anatomical arrangement of the parts is responsible for a check in the downward progress of the pus. There is thus the closest similarity in the progress of events which result in necrosis of cartilage, no matter in what position the necrotic area of cartilage is situated.

The chronicity of quittor is attributable to the slowness and difficulty with which necrotic cartilage is eliminated. Necrotic tissue always provokes a reaction in the immediately adjacent living tissues. In the case of cartilage this reaction appears to be at a minimum, and the separation of the dead from the living is effected with great slowness. Once the process of separation is complete the elimination of the dead material is frequently impossible, owing to the smallness of the aperture by which alone escape is possible. Evidence of this is commonly obtained in the operative treatment of old standing quittors by the discovery of necrotic cartilage completely detached, and more or less embedded in granulation tissue. Such necrotic areas of cartilage are constantly bathed in pus, and their septic condition is an important factor in the perpetuation and extension of the morbid process.

At the conclusion of his address, Prof. Gofton gave a demonstration by performing the radical operation on a horse's fore foot. Specimens were also displayed to the members.

DISCUSSION.

Mr. SAMPSON said they had all been very interested to hear Prof. Gofton and see his able demonstration on the foot. Prof. Gofton would be very pleased to answer any enquiries or suggestions that might be made.

Mr. BOWES: I am sure we are all very much obliged to Prof. Gofton for coming down from Edinburgh and

giving us this interesting paper and a description of the operation. As Prof. Gofton says, there are quittors and quittors, and a good many of the cases we call quittor that recover comparatively easily are not quittor cases. So far as a real bad quittor is concerned, my experience of late years, since I am not quite so active as I used to be, has not been very successful. In the old days I have seen what seemed to be very radical operations, but they were not done with the accuracy that Prof. Gofton has shown. The milder cases I have found to recover after injections. I want to refer to the treatment which has become more common recently—the injection of vaccines. I have used anti-suppurine, which consisted of mixed cultures of the organisms generally present in such conditions. During the past few years I have used a good deal of anti-suppurine, and the majority of the cases have done extremely well. The only other treatment necessary is cleanliness of the part, but many of the cases had been on farms where cleanliness had not been observed. I should be glad to hear from Prof. Gofton if he has had experience in the use of vaccines. If a fair percentage of recoveries could be got by that treatment alone he personally would undertake it rather than the operation.

Mr. MCKINNA said he was very interested in what Mr. Bowes had said, and he was also interested to know whether any other member had tried the treatment by injections of anti-suppurine. He had been wonderfully successful in the treatment of quittor by treating symptoms, as it might be said. He had used perchloride of mercury, not to act as a caustic, but as a powerful antiseptic. He had never been much encouraged to employ the radical operation. Each man has to use his own peculiar treatment in cases that arise, but he had not done that particular operation, which was most interesting to him. They had always to consider the matter from the standpoint of "Would it pay?" and they had to look at things from the commercial standpoint, and not from the surgical point of view in which they would be so much interested.

Another member asked if Professor Gofton could explain how one very often got permanent lameness after operation in the fore foot, but not in the hind.

Mr. CRAWFORD said he had been very interested to see the operation done. The point was, how long was it going to take afterwards for the filling up of the hole that was left. Getting back to work was what they had to consider. Like Mr. Bowes, he was a great believer in anti-suppurine.

Prof. GOFTON: Six to eight weeks.

Mr. A. ELLISON thanked Prof. Gofton for his extremely interesting paper. Some years ago he got a number of cases of quittor. He used to find by the probe what portion of the cartilage was diseased, and then endeavour to make an ordinary wound of it, and remove any portion of cartilage found to be diseased. He had seen an animal go back to work again sometimes in three weeks or a month.

Mr. T. C. FLETCHER said he thought that Professor Gofton's radical operation was one for which many of them had not the time or patience. He had been careful in watching the operation as performed by Prof. Gofton, and he must say that before he attempted it on a living foot he would try all the means possible, including anti-suppurine. He was sure they were all extremely obliged to Prof. Gofton for his illustration of the mode of operating.

Mr. W. ACKROYD said he had to thank Professor Gofton for his demonstration. He would like to have some idea of the treatment of quittor at varying stages. He took it that the radical operation which so many shied at was for a chronic case, which had not yielded to other methods, and he would have liked to have heard something as to other methods. There was one hopeful point about Prof. Gofton's observations, and

that was that one need not remove the whole of the cartilage. As other speakers had remarked, it was not a question of surgery, it was a question of what one could do economically for one's client. It would be interesting to know what number of horses failed to go sound after a radical operation.

Mr. SAMPSON said it would be interesting to know how long Prof. Gorton advised leaving an ordinary case of supposed quittor before attempting a radical operation. That was, assuming that quittor had been treated for one, two, or three months, what was the earliest time the Professor would advise a radical operation. Personally, he would be one of the shy brigade. He had seen operations performed, but lameness followed.

REPLY.

Prof. GORTON discussed the partial operation as compared with the radical operation. Personally, he preferred, as far as it was possible, the partial operation. His experience of the radical operation was that sometimes, though not always—not in the greater percentage of cases—one got a lameness which was permanent. He, therefore, preferred to do the partial operation as far as it was possible, and if one could trace and discover localised areas of cartilage, in the great majority of cases if the necrotic cartilage was removed with a minimum of injury to the remaining healthy cartilage, a satisfactory recovery was secured in about half the time required for a radical operation. The cases for radical operation were those which were old standing, where one found the necrosis had extended well forward. In these old standing cases, which had been going on indefinitely, it was not much use attempting anything but the radical operation since such cases almost invariably presented several areas of necrotic cartilage connected with each other by sinuses which were frequently difficult to trace.

With regard to the question of lameness, it was admitted that in a certain proportion of cases permanent lameness did follow the radical operation. The question had been asked—What was the cartilage replaced by? It was obviously replaced by the reproduction of the surrounding parts, that was to say, fibrous tissue. It had been suggested that the lameness was due to the newly formed fibrous tissue being less yielding, but as a matter of fact fibrous tissue was more yielding than cartilage. So far as his experience went, it had led him to the conclusion that it was the injury to the ligament which was responsible for the lameness, since lameness only followed when operative interference was carried into the region of the ligament of the joint.

Mention had been made of the open joints. This was always a possible accident of the radical operation, but the great point was to recognise when the joint was opened, and then take adequate steps to prevent serious trouble following. The accident did not necessarily make the case hopeless. Sepsis and rough handling of the cartilage, involving fresh injury to it, were two main explanations of failures of the partial operation.

The economical side of the operation had to be taken into consideration, but situated as he was, he was only too glad to be able to secure cases to operate upon for demonstration purposes, independently of the economical side. The private practitioner could not, of course, accept cases on those lines.

He could not say anything as to the value of anti-suppurine in the treatment of the disease. Unless one made one's own vaccine from the patient, it was just a chance whether one got the right organisms or not. If he were going to use a vaccine he would prefer to make it from the patient. One of two things was necessary to bring about a cure in quittor, the elimination of the cartilage which was diseased, or the rendering of it aseptic so that the tissues could grow round it. He did not know whether the latter ever occurred, but

theoretically it seemed possible. With anti-suppurine one might conceivably destroy the infection and thus permit of healing and recovery.

On the motion of Mr. Bowes, seconded by Mr. Fletcher, Professor Gorton was cordially thanked for his address, and a vote of thanks to Mr. Sampson for presiding concluded the meeting.

J. CLARKSON, Hon. Sec.

WESTERN COUNTIES VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The 71st general meeting was held at the Great Western Hotel, Taunton, on Thursday, November 27, when the President, Mr. C. E. Perry, of Bristol, occupied the chair, other members present included Messrs. P. G. Bond, Plymouth; E. W. Bovett, Bridgwater; A. J. Down, Sampford Peverell; R. E. L. Penhale, Torrington; Wm. Roach, Exeter; and H. E. Whitmore, Langport.

The minutes of the last meeting were read and confirmed.

Apologies for non-attendance were read from Prof. Hobday, Messrs. Wm. Ascott, W. H. Bloye, John Dunstan, G. H. Gibbins, Wm. Penhale, W. H. Richardson, A. G. Saunders, G. Parker Short, and W. P. Stableforth.

Condolence. Mrs. Elder wrote thanking the members for their expression of sympathy on the death of Mr. G. H. Elder.

Since the last meeting the death had occurred of Mr. Thos. Olver, of Truro. Mr. Olver was one of the founders of this Association, and always took a keen interest in its welfare. The Hon. Sec. was requested to convey a vote of condolence to his relatives.

The Hon. Sec. was directed to convey to Mr. G. Parker Short, of Torquay, who is suffering from a long and severe illness, a message of sympathy and hopes for his speedy and complete restoration.

New Member. Mr. A. HART, of Honiton, was unanimously elected a member of the Association.

TENTH INTERNATIONAL VETERINARY CONGRESS.

A letter from Mr. Garnett as to payment of subscriptions was referred to the Hon. Treasurer to deal with.

PRESIDENTIAL ADDRESS.

MR. C. E. PERRY, Bristol.

Gentlemen,—I must first of all thank you for electing me President of your Association for the year, and I must say I very much appreciate the honour you have conferred upon me. I appreciate it for more reasons than one; when I first came to your meetings, some fifteen years ago, I felt quite at home at once, although I did not personally know any of the members present. There is always that feeling of good fellowship at all your meetings which I cannot express in words. I have attended meetings of other veterinary associations, and I am convinced there is not the good feeling existing towards one another that we have in this Western Counties Association. I never remember attending a meeting of this Association but I have gained some knowledge, and my regret is that I cannot attend more meetings than I do, owing to places of meetings being too far from me.

It is usual for the President to say something about the veterinary profession at the time present. The most important matter now before the profession is the Veterinary Surgeons Act Amendment Bill now before

Parliament, and I think we all hope that it will soon become law. It is absolutely necessary to put the Royal College of Veterinary Surgeons' financial position on a sound basis, and no doubt the Bill will do so. I hope that one of the first things done by the Council when they are in a financial position to do so, will be to give the Registration Committee more power to put down quackery and patent medicines. Money is wanted to carry out the work, and at present the Committee are very much hampered for the want of funds. I hope the Council will study the wants of the general practitioner before they start rebuilding the Royal College of Veterinary Surgeons on a better site, as has been suggested, or enlarging the museum and library. These improvements we would all welcome, but there are many other more pressing needs that require attention first.

Next year an International Veterinary Congress will be held in London. Some £4000 are required to finance the Congress, and I think it is the duty of every veterinary surgeon in the country to contribute to the funds. Our Treasurer has given us a good lead by subscribing one hundred guineas; we, as an Association, have also subscribed, but we all individually ought to subscribe what we can afford.

This Veterinary Congress ought, and I think will, bring home to the general public the important position the veterinary surgeon ought to occupy in the country. What are the prospects of the veterinary surgeon; how do we stand to-day as a profession? Some people say the day of the horse is going, that very shortly there will be no horses to treat, and that we as a profession must go too. That, I think, is certainly wrong. No doubt motor traction has come to stay; horses are being replaced daily by motor for carriage work, and for general hauling. Some veterinary surgeons, particularly town men, have, and will suffer, but it is my candid opinion that the horse will always be wanted in this country. Hunters are more valuable than ever, the Army horse is a necessity, and farm horses are required on the land; in fact horses of all descriptions are more valuable to-day than I ever remember.

Cattle practice is on the increase, becoming more scientific and more remunerative. To-day there is more demand for milk than ever there has been, and in future milk will be one of the principal articles of diet. I think there is a great future for cattle practice.

Some years ago many veterinary surgeons would not condescend to undertake the treatment of dogs; but to-day it is one of the most lucrative branches of the profession, and is certainly very much on the increase. Personally, being veterinary surgeon to several dog shows and clubs, I am brought into contact with owners of dogs, and dog practice is a very important part of my every-day work.

Then, again, recent legislation has made more work for the veterinary surgeon. The Coal Mines Act, making it compulsory to have every horse malleined before being put underground, and providing for better veterinary treatment for horses when underground, has certainly brought grist to the mill for many like myself who attend colliery horses and go underground.

The Tuberculosis Order has made work for veterinary inspectors and will make a lot of extra work when the Milk and Dairies Bill is passed into law, making compulsory periodical inspection of all dairy cattle.

Apart from general practice the public are rapidly realising the need for proper control of the milk and flesh food supply, and who is more fit to do that duty than the veterinary surgeon? Further, public health legislation is certain to bring more work to us as a profession.

I should like you to think how our daily work has changed since I was a pupil twenty years ago. Then

tuberculin and mallein were not in daily use, there was no preventive vaccine for quarter-evil, no preventive vaccine for distemper, no anti-suppurine, streptococcine, etc. We had no curative injection for milk fever. Think what these new treatments and diagnostic agents bring us in as a profession.

I think, gentlemen, from the remarks I have made we may conclude that although our outlook is perhaps not so good as it was some years ago, yet it is not so bad as we are sometimes apt to think it is, and although our work has changed and in some way diminished, we must be thankful that it has increased and we trust it will still continue to increase in many other ways. Gentlemen, I thank you.

On the motion of Mr. Whitmore, seconded by Mr. Bovett, the President was thanked for his address.

CLINICAL CASES.

Mr. BOVETT exhibited two photographs of a twelve-year-old mare on which he reported.

On May 31st, 1912, I examined an ordinary farm bay mare with some skin affection which covered the whole of her body, the eruption seemed to come in crops, as some of the nodules could only be felt under the skin; others could be clearly seen resembling urticaria; others were rubbed blood red, and some were drying and healing under a scab. I had her dressed all over with the following lotion: Ol. tereb. Oj., Ol. picis Oj., Whale Oil Oj., Sulph. sub. lbij., this was well rubbed in with a scrubbing brush from the tip of her nose to the tip of her tail and all four legs, and gave powders of As. gr. x, with Ferri sulph., in the feed twice daily, the mare could not be worked, so the lotion was allowed to remain on, or rubbed off at grass. She was dressed over with this lotion four times, and continued the powders until the beginning of August, when I wrote my late friend the late Mr. Elder, and he suggested trying Pot. iodide. This I did for some time, but with negative results. I then wrote Prof. M'Fadyean, and he being away his assistant advised cod liver oil internally, suggesting it was due to malnutrition of some of the internal organs. This I did for some weeks, and also dressed her all over with cod liver oil several times, but with negative results. Early this month I received a message saying owner would not have anything else done to her, as she continually went down as if in pain, so I went and saw her and after having a couple of photos taken of her, had her destroyed, and made a post-mortem examination.

All the internal organs were healthy with the exception of the accessory lobe of the right lung, which was full of rounded tumours of the size of from a 5/- piece to 4 or 5 in. in diameter and somewhat flattened, and when cut into looked to the naked eye like the ray fungus of actinomyces looks under the microscope, or like a number of true ticks crowded together. The skin lesions did not go through the skin, the inside being quite smooth. Below each pin, underneath her arms and around her tail and behind her withers on either side were large tumours which resembled ordinary muscle when cut into, but quite bloodless, in fact they were yellow instead of pink. I sent on these parts to Prof. M'Fadyean and received his reply, which I have here. The mare was in very good condition when I saw her first, and you will see from the photos she had not lost condition in spite of the terrible irritation she was in for so long.

"Dear Mr. Bovett,

I duly received your letter of the 4th inst., and the specimens from the horse. Although we have devoted a good deal of time to microscopic examination of the parts, including skin, lung, and tumour, I am sorry to say that we have not been able to determine with certainty what was the cause of the mischief. The

lesions are very peculiar in character, and I do not think I have ever seen anything exactly the same before. I am quite satisfied that they have been caused either by bacteria or by some animal parasite, but we have not been able to identify any parasite in them. Can you tell me whether the mare had ever been out of England or not, and whether there was an opportunity for the disease to spread to other horses while she has been ill.—Yours faithfully,

J. M'FADYEAN.

Nov. 8th, 1912."

In reply to the points raised in Sir John M'Fadyean's letter I may say that the mare was bred in this district and had always been worked on the farm. There was no sign of the disease in any of the horses or other animals she came in contact with.

EPIZOOTIC ABORTION.

The PRESIDENT (Mr. Perry) : I have the care of a herd of 21 Jersey cows, and for two or three years have experienced considerable trouble from abortion. Recently three aborted in quick succession. I then took samples of blood from the remaining eighteen, and sent to the Royal College for testing, with the result that four more were certified as affected. The owner declared that this could not be so, but about three weeks before due to calve, three more aborted. I do not believe in the idea of "feeding off," and the affected cows are isolated and a separate bull kept for them.

Mr. PENHALE : In several cases of cows aborting within three weeks of the time due to calve, I have given it as premature birth, although the Royal College has said it is epizootic abortion. One of the best places to look for the bacillus is in the stomach of the calf. I certainly think that "feeding off" is not to be advised.

STRANGULATION.

Mr. BOND : I have recently come across three interesting cases in polo ponies. One of these was at a local show; the pony was shown from about 2 to 3 o'clock, and while in the ring was ridden by a heavy gentleman acting as judge. Shortly afterwards it was taken as if suffering from severe colic pains. A drench was given, but the animal gradually got worse, and was shot about 12 o'clock the same night. A post-mortem examination revealed a pedicle of fat about the size of a duck's egg, hanging down in the form of a string from the mesentery, and this had become twisted several times around the small intestine, causing strangulation. The other two cases were very similar.

Mr. PERRY : I was recently called to a case of colic, not a severe attack, but the animal had intermittent attacks lasting for about 10 minutes or so at a time. During the first day the horse had a drink or two of water and also passed manure and urine, but died in about 40 hours. On making a post-mortem examination I found the cæcum inverted into the large colon.

Mr. WHITEMORE . A short while ago I had a case where a horse gave more than the usual indication of the seat of the trouble. The first day the symptoms were of colic. The second day the patient repeatedly kept poking his nose into his flank, and suspecting inguinal hernia, I made several examinations, per rectum, without success, and on the third day he died. A post-mortem revealed a twist of the small intestine.

Mr. DOWN : I recently attended at a farm for the purpose of castrating two colts, and in the course of preparing for the operation I noticed that one of them appeared unwell, and on closer examination found it was suffering from tetanus. I made an injection, and of course declined to castrate. These colts had been brought home from an off-farm two days previously, where a cow had been killed by lightning. The farmer said to me "Has the colt been struck by lightning?" and I said I thought not. On the 3rd day the colt

died, and the same man that skinned the cow was employed to skin him. The owner persisted in making a claim on the insurance company, and in the ordinary way I was asked to give a certificate; this I did, certifying that the colt died from tetanus, but could not say it was caused by lightning.

WM. ASCOTT, Hon. Sec.

ANNUAL REPORT OF THE CIVIL VETERINARY DEPARTMENT PUNJAB.—By Lieut.-Col. J. FARMER, Chief Superintendent. [ABSTRACT.]

(Concluded from p. 366.)

BREEDING OPERATIONS.

Ninety-one bulls were supplied from the Hissar Cattle Farm on indent from 16 district boards and 13 were purchased locally. At the end of the year under report there were 544 bulls.

The system of supplying bulls is satisfactory. Some of the district boards purchase bulls for Rs. 200 and sell to responsible men for half the price. This is a very good method, but a sufficient number of men do not come forward to purchase. The most satisfactory method would be for the agricultural banks to purchase; this would place the responsibility of looking after the bull upon more people, because a larger number would have a share in the bulls. The Chief Superintendent has consulted Mr. Langley, Registrar of the Co-operative Credit Societies, who has very kindly helped him, and the Inspectors of the Banks have been consulted in the districts.

Cattle-breeding will always be handicapped until the letting loose of brahmini bulls is put an end to, or it be arranged for the pious hindus to consult the department before letting a bull loose. The present pious man cannot and does not wish to pay the price of a good animal, as prices have so greatly increased in the last few years. The department has carefully considered religious sentiment in this matter. The best way to deal with these useless animals would be to issue orders that all inferior brahmini bulls should be reclaimed by their original owners. If the animal is not claimed, it can be either sent to a goushala, if so desired, or castrated and sold by auction, and the money credited to the district board to go towards the purchase of a good bull.

Pious hindus in the future wishing to present a brahmini bull should be asked to contribute whatever money they wish to spend, to the district board who should add the necessary amount and purchase a good animal. It is more expensive to feed and keep poor than good stock.

At the close of the year there were 68 horses and pony stallions at work in the non-selected districts which is two less than the sanctioned scale. The produce of these animals is good.

There were 74 donkeys at work in the districts during the year which is one short of the sanctioned scale. Eight jacks were indented for and supplied during the year from the Hissar Farm.

Covering registers are now being more carefully kept, and the department is endeavouring to get more information regarding the young stock produced. The shortage of veterinary assistants rather handicaps this, as their time is fully taken up with treatment of diseases and castrations.

Horse shows were held in six districts during the year.

Cattle fairs were held in nineteen districts. Most of the important shows were attended by an officer of the Department.

Out of the balance of ten merino rams reported in paragraph 24 of the last year's report, four still remain.

Eight merino rams and 25 ewes were imported during the year and sent to Kangra. Merino sheep-breeding now looks more promising. The sheep-owners have been shown what is necessary. Those who opposed have now been convinced.

The establishment of subordinates at the end of the year was 190:—Veterinary Inspectors 15; Veterinary Assistants, 1st grade 34; 2nd grade 70; 3rd grade 71.

This is an increase of six men over the previous year. The Department is still in need of more men. The appointment of deputy superintendents and more veterinary inspectors and of assistants is now being considered.

General remarks.—The question of the veterinary staff being transferred to the district boards has been settled and the staff is to remain provincial.

Proposals to augment the staff by three Deputy Superintendents and to have one Veterinary Inspector for each district are before Government. It is to be hoped that these appointments will be sanctioned as the Superintendents have their time more than fully occupied, and have to work hard to keep the routine work up-to-date.

Cattle-breeding is progressing, but unless the department has extra inspectors, it is impossible for Superintendents to inspect every village and explain to the people what is actually needed. The Superintendents are constantly being consulted on matters regarding breeding; the people have now commenced taking a greater interest in cattle-breeding, as they see from the bulls supplied what can be done by the Department.

The question of ostrich breeding is under consideration. It is to be hoped that the matter will be carefully considered before being started.

Messrs. Woodley and Taylor have worked zealously, and the Chief Superintendent's thanks are due to them for the assistance they have rendered.

ANNUAL REPORT ON THE GOVERNMENT CATTLE FARM, HISSAR.

Review of the Chief Superintendent.

In consequence of the abolition of the Inspector-General, Civil Veterinary Department, the control of the Government cattle farm was transferred to the provincial government, and is now worked under the Chief Superintendent, Civil Veterinary Department.

The year under report has been remarkable mainly in that for the second year in succession there has been a partial failure of the rains; in consequence very little good grazing has been available and only 1,000 maunds of hay have been collected. The barani crop has been a failure. The canal supply is insufficient, and an experiment with a tube well for irrigation purposes is to be carried out. Owing to the excellent system of having rotation crops the cattle have been kept in good health in spite of scarcity conditions.

Owing to the increased demand for bulls for the districts and bullocks for the military department the present sanctioned strength of 1,500 cows will have to be raised to 2,000. The percentage of calves born during the year is smaller than it has been for some years; this is due to two famine years in succession.

The object of the farm is to produce the best bulls and jacks, and thereby to improve the breeding in the districts. If it were not for this, Government would be unable to procure the number of bulls required for the districts, and the jacks would have to be purchased in Europe.

The present quasi-commercial system of charging a nominal price for an animal issued to the district boards in the Punjab, and a higher price for one supplied to another province, prevents the farm from being self-supporting, and the idea of running the farm on commercial lines should therefore be abandoned.

The number of jacks issued is very creditable, and

the indents for the Punjab have been fully complied with. Mules issued to the service during the year were a very fine lot. Mule breeding in Hissar is a great success, and the mules are admittedly the best bred in India. The foalings during the year have been satisfactory.

Sheep breeding has progressed satisfactorily.

The revision of the farm establishment is now before the Government.

Mr. Branford has worked hard and deserves credit for his labours.

Report by Mr. Branford, Superintendent.

During the year under report the farm was in charge of Lieutenant-Colonel Farmer from April 1st to June 8th, and under my charge for the remainder of the year.

The farm is up to the present, still being run on the same lines as when under Inspector-General, Civil Veterinary Department. Stock in the shape of siege train bullocks, ordnance and transport mules, and donkey jacks are being issued to the Army Department; and stud bulls, donkey jacks, and half-bred Merino rams to district boards, native states and private buyers. Every endeavour is being made to maintain the stock at the high level of excellence reached while the farm was controlled by the Inspector-General, Civil Veterinary Department, and in this connection it is of advantage that the farm is under the supervision of its late superintendent and still reaps the result of his experience.

Apart from the grass famine the year has been a successful one. The demand for all classes of stock issued from the farm appears to be on the increase.

The years of scarcity have resulted in comparatively cheap labour and many improvements, especially as regards the cultivation, have been carried out, and provided there is a normal supply of canal water and the rains do not again fail, it is hoped to save sufficient fodder to put the farm into a safe position as regards the next period of scarcity.

Hæmorrhagic septicæmia broke out in the rains in the Chaoni Bir. In my opinion many parts of the Bir adjacent to the canal are contaminated with the organism of hæmorrhagic septicæmia, and after long breaks in the rains when puddles of water are almost dried up, the organism is present in sufficient quantities to form a fatal dose for any susceptible animal drinking; whereas a good fall of rain dilutes the bacilli sufficiently to render them innocuous. The same theory is applicable to outbreaks occurring here in the dry season as the result of floods and leakages from the canal. The organism is probably normally present in the canal water, in a state of dilution so high as to be innocuous, but as the puddles formed by over-flows, etc., dry up, a suitable temperature for reproduction of the organism is produced, and also the volume of water is lessened by evaporation, with the result that any animal drinking from such a puddle contracts hæmorrhagic septicæmia. Probably the policy inaugurated last year of preventing canal leakage as far as possible, and preventing access of cattle to low-lying areas liable to receive over-flows, has contributed to our immunity from the disease except in the rains. The disease caused 5 deaths as against 32 last year.

Black-quarter was responsible for 12 deaths, as against 6 last year.

Strangles.—Mild outbreaks only have occurred, causing no deaths.

Navel-ill still occurs, and with the large number of births and the limited staff on the farm, it is almost impossible completely to eradicate it.

Foot-and-Mouth Disease, as regards deaths, has been a contributory cause only, but in combination with the grass famine has had serious effects in retarding growth and development.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Dec. 15, 1913

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Foot-and-Mouth Disease.

The existence of foot-and-mouth disease amongst cattle at Whitwell, near Welwyn, Hertfordshire, was confirmed on Monday. The usual precautions were taken to prevent the spread of the disease, and an Order has been issued prohibiting the movement of animals in a large area surrounding this affected farm.

The disease broke out in a herd of 53 heifers and bullocks, over half of which was affected. The animals have been slaughtered. The district scheduled under the Order of the Board of Agriculture comprises portions of the counties of Bedford, Bucks, and Cambridge, practically the whole of Hertfordshire, and the petty sessional division of South Mimms in Middlesex.

The outbreak occurred at Rose Park Farm, belonging to Mr. James Francis Tooley, and the subsequent Order prohibiting the movement of cattle in a large area surrounding the farm, have caused no little consternation in the district in view of the approach of Christmas. At Hitchin the Christmas fat stock show and sale, which was to have taken place on Tuesday, has had to be abandoned.

It is announced that owing to the outbreak the Hertfordshire Hounds, of which Lord Cavan is Master, will not meet until Wednesday, December 24th, at Chicksands Priory.

The cattle, over 50 in number, which were slaughtered, were cremated at Whitwell on Wednesday under Government Order.

The Tuberculosis Order—A Bad Case.

At the Salford Police Court on Friday, December 12th, F. Unwin, of Pump Farm, Werrington, near Stoke-on-Trent, was summoned for a breach of the Tuberculosis (Animals) Order.

Mr. Whitehead, veterinary surgeon to the Salford Corporation, stated that on October 21 he found a cow belonging to the defendant at the Cross Lane cattle sidings. The animal was in such a condition that almost anyone could see that it was diseased. When it was slaughtered a disinfectant had to be used before it could be thoroughly examined. It was the worse case of tuberculosis that had ever come under his notice. On October 24 witness saw four other beasts belonging to the defendant, and Unwin said he had paid £11 10s. for them.

In reply to the Stipendiary, Mr. Whitehead said that had the animals been sound they would have been worth at least £40. They were slaughtered, and three of them were diseased.

The defendant did not appear.

Mr. J. W. Jackson, Deputy Town Clerk, said the Board of Agriculture regarded this class of offence as most serious.

The Stipendiary (Mr. Peter Wilson Atkin) said that the first animal mentioned was evidently in a very bad condition, and the defendant would be fined £15 and three guineas costs. In the other case the defendant must be fined £15 and 5s. 6d. costs. The total fines amount to £33 8s. 6d.—*Manchester Evening News*.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LONDON,

At a meeting of the Board of Examiners held in London on December 8th for the Written, and on Dec. 12th, 15th, 16th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:—

Mr. A. H. Adams *	Mr. W. H. Priston
W. P. S. Edwards	K. H. Soutar
C. E. Huston	H. S. Wright
W. B. Howe *	G. Williamson *
G. F. Marais	

The following passed their Third Examination:

Mr. J. W. Beaumont *	Mr. P. S. Sparling
H. Chown	J. H. Stewart
J. Daly *	R. T. Smith
J. A. Edwards	L. D. D. Sewell
J. M. Knighton	J. W. Stanley
G. Simons	H. B. Williams *

The following passed their Second Examination:

Mr. A. Bayly	Mr. D. E. McRae
G. H. Bennet	E. O'Kelly
T. J. Dixon	A. Temple
E. W. Garry	P. F. Woodland
L. St. Bel Gollidge	

The following passed their First Examination:

Mr. P. W. Bloye	Mr. J. G. Foulston
J. A. A. Barlow	W. Gibson
E. C. Bowes	

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN LIVERPOOL.

A meeting of the Board of Examiners held in Liverpool on Dec. 8th for the Written, and on Dec. 11th and 13th for the Oral and Practical Examinations, the following gentleman passed the Final Examination;

Mr. R. L. Lewis.

The following passed the Third Examination:—

Mr. G. Lloyd	Mr. E. J. B. Sewell
--------------	---------------------

The following passed the Second Examination:

Mr. S. S. Herbert	Mr. B. Whittam
S. T. Jackson	

The following passed the First Examination:—

Mr. T. Hare.

REVIEW.

A TEXT-BOOK OF HORSE-SHOEING FOR HORSESHOERS AND VETERINARIANS.—By A. LUNGWITZ, formerly Member of the Royal Saxon Veterinary Commission, late Instructor in the Theory and Practice of Horse-shoeing, and Director of the Shoeing School of the Royal Veterinary College in Dresden, Germany; and JOHN W. ADAMS, Professor of Surgery and Obstetrics, and Lecturer on Shoeing in the Veterinary School, University of Pennsylvania. Eleventh Edition, with 229 illustrations. Pp. 216. Price 7s. 6d. net. (J. B. Lippincott Company, Philadelphia and London).

This widely-known work has now reached its eleventh edition. An American translation of the tenth edition

has been in use for some years in the United States, and we are glad that the eleventh is now offered to English readers also.

A book of such established reputation does not demand much critical review. All that is necessary, we think, is to briefly indicate its scope. The first chapter—a long one—is devoted to anatomy, and, after briefly sketching the gross anatomy of the horse, proceeds to deal in much greater detail with all the components of the foot, including its locomotory attachments. The second chapter upon "The Foot in its Relation to the Entire Limb," is mainly physiological, and deals with growth and wear, the physiological movements of the hoof, lines of flight of hoofs in motion and the influence of weights upon them, and similar questions. Another long chapter follows upon the shoeing of healthy hoofs, and covers the whole subject—restraint and manipulation, preparing the foot, making, choosing, shaping, fitting, and nailing of shoes, and shoes for special classes of horse. This is followed by three shorter chapters upon the shoeing of forgers, winter shoeing, and the care of the hoof. Finally, we have three more chapters upon the shoeing of defective hoofs and lame horses—including general considerations, the various acute and chronic inflammations of the foot, and defects in the form and continuity of the hoof, and a short chapter on the shoeing of mules, asses, and oxen concludes the work.

We know no small work which treats the subject with such fullness of detail as this one. It condenses a great amount of information into a comparatively small space, and is simply and clearly written throughout. It will be very useful indeed to veterinary students and practitioners, and almost invaluable to farriers of the better class. We make the latter reservation advisedly, for, in this country at least, we know that there are still many farriers who will not care to go into the subject so deeply as this book will take them. This is our sole criticism of the work—it contains more information than some of the men for whom it was written are capable of assimilating. The rest will find it valuable, and we welcome it as a solid addition to our professional literature.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Dec. 12.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. H. M. Durrant retires, receiving a gratuity Dated Dec. 13

Lieut. F. B. Sneyd resigns his commission. Dated Dec. 13.

SPECIAL RESERVE OF OFFICERS.

ARMY VETERINARY CORPS.

F. B. Sneyd, late Lieut Army Veterinary Corps, to be Lieut. Dated Dec. 13.

Messrs. MAW, SON & SONS, of Aldersgate Street, London, E.C., have again been appointed contractors for the supply of veterinary surgical instruments and appliances to the Army Veterinary Service.

Personal.

MACFARLANE.—At 385 Great Western Road, Glasgow, on the 9th inst., the wife of James Macfarlane, M.R.C.V.S. a son.

W. Bro. G. H. WILLIAMS, M.R.C.V.S., was on Tuesday, 9th inst., installed Worshipful Master of the Lansdowne

Lodge of Unity, No. 626. At the close of the installation, the customary banquet was held, W. Bro. G. H. Williams, Worshipful Master, presiding. There was a good attendance of Provincial Grand Lodge officers. The toasts were interspersed with songs by the Worshipful Master, Bro. R. Heath, Messrs. W. H. Munday and R. Moore, and a recitation by W. Bro. W. H. Brinkworth.—*The Wiltshire Gazette*.

Mr. T. M. INGLIS, M.R.C.V.S., has been sworn a Justice of the Peace for Forfarshire. He was quite recently, unanimously elected Chairman of the Parish Council of the Royal Burgh of Forfar.

OBITUARY

ALEXANDER MORRISON, M.R.C.V.S., Rhynie, Aberdeenshire. 1862, Graduated, Edin: June, 1880.

Mr. Morrison died on Dec. 9th, from anthrax, after five days illness. Aged 73 years.

EDWARD O'REILLY, M.R.C.V.S., Academy Street, Navan, Co. Meath. Lond: August, 1903.

Death occurred on Tuesday, Dec. 9th.

WM. WRIGHT, M.R.C.V.S., Thornhill, Dumfriesshire. Glas: July, 1882.

Death took place on Dec. 16th, from arterio-sclerosis, at the age of 53 years.

The late Mr. J. A. Thompson, J.P., F.R.C.V.S.

Mr. Thompson was born in Ballynahinch on Jan. 11, 1857, and was a son of the late Mr. Robert Thompson of that town. After receiving his primary education, he passed to the Royal School, Edinburgh, where he continued his studies, subsequently entering the Royal Veterinary College in that city, from which he qualified in 1881. For a brief period he acted as locum tenens to a distinguished practitioner in Wales, and in 1883, after a short residence in Lisburn, he came to reside in Lurgan, where he rapidly built up a large practice and took a prominent place in the life of the community. On the establishment of the North of Ireland V.M.A. some years ago he acted as its first treasurer, and in its second year was elected President. Mr. Thompson was also a member of the V.M.A. of Ireland, and of the Irish Central V.A., a veterinary inspector to the Department of Agriculture for Ireland, and to the County Councils

of Armagh, Antrim, and Down, and veterinary inspector to the Lurgan Urban Council and the Moira and Lurgan Rural Councils. His wide experience in his profession made his name well-known throughout Ulster, and he was frequently called upon for consultation in difficult or obscure cases. Many years ago his practice in Portadown necessitated his establishing a permanent surgery there, and this has for some years past been under the management of his eldest son, Mr. Robert W. Thompson M.R.C.V.S. In 1890 Mr. Thompson was elected to the membership of the old Board of Town Commissioners in Lurgan, and this position he retained with credit to himself and with much advantage to the ratepayers for thirteen years. Four years ago he was appointed to the Commission of the Peace, and it was generally recognised that no more popular appointment to the local magisterial bench had ever been made. He was ever very keenly interested in agricultural concerns, and the inauguration of the Lurgan Agricultural Association, and the success and popularity of its shows was largely attributable to his initiative and energy. He was a devoted member of the First Presbyterian Church and for years a member of its session. In Masonic circles he was much esteemed; being a P.M., and one of the founders of Ulida Lodge No. 151, a past officer of the Provincial Lodge of Armagh, a P.K. of Royal Arch Chapter No. 24, and an officer of Preceptory No. 134.

The funeral took place on Thursday afternoon, the cortege being one of the largest and most representative seen in the district for many years past. The chief mourners were Mr. Robert Thompson, M.R.C.V.S., Portadown; Dr. John A. Thompson, Edinburgh; and Mr. Charles G. Thompson, M.R.C.V.S., Lurgan (sons); Messrs. R. S. Hanna, Drumaness, and T. Briggs, Hollywood (brothers-in-law); Messrs. Vincent Briggs, Hollywood, and Robert Pringle, Belfast (nephews); Mr. J. Thompson, Hillsborough (cousin). On arrival at the New Cemetery, the remains were carried to the graveside by four relays of bearers—representative Freemasons, the members of the veterinary profession, members of the Lurgan Agricultural Association, and the staff of the Imperial Hotel, Portadown.

The floral tributes were numerous and very beautiful.

At a special meeting of the Lurgan Town Council, Mr. H. G. MacGeagh, D.L. (chairman) made touching reference to the death of Mr. Thompson. He said before proceeding with the business of the meeting the Council had a duty to perform, and to him, and he was sure to them also, it was a very sad one. Since they last met one of the most esteemed officials of the Council was no more with them. Mr. Thompson was a big man in every sense of the word. He was admired and esteemed, and indeed almost loved by every person with whom he came in contact. He had known Mr. Thompson for thirty years, and never knew of anything that was not to his credit. His death was much to be deplored, and he would be greatly missed in the town and in the wide circle of his friends and acquaintances. It only remained for them to extend their sympathy to Mr. Thompson's bereaved wife and children, and personally, on his own behalf and as Chairman of the Council he would propose that this be done.

The motion was passed in silence, the members standing with bowed heads.—*The Lurgan Mail*.

VOL. XXVI.

ABORTION IN SHEEP.

The Departmental Committee appointed by the Board of Agriculture to enquire into epizootic abortion have lately issued their third and final report on "Abortion in Sheep." An appendix by Sir John M'Fadyean and Sir Stewart Stockman is issued with it as a separate publication, and contains a detailed account of the experiments and observations upon which the report is based. The whole is of the greatest value to veterinary surgeons, and the following is only a very brief summary of it.

The report commences with some final references to contagious abortion in cows. The Committee are satisfied that "by means of one or other of the methods of diagnosis described in a previous report it is now possible to distinguish with practical certainty between cases of contagious abortion in cows and those of a sporadic or accidental character," and that the agglutination test by itself appears likely to be very serviceable in future in detecting the disease in its incubative period. Not so much progress has been made with regard to the immunisation of cattle, but the Committee are satisfied that it is already possible to confer a high degree of immunity, and regard this question as now beyond the laboratory stage of investigation. They suggest that it should be left in the hands of the Board of Agriculture for further observation and report.

But the great value of the report lies in its revelations concerning ovine abortion. The disease is both more common and more widely spread than many men suppose, as the long list of affected counties given in the report shows. Further, though Bang's bacillus is known to be capable of producing abortion in sheep, it is not the common cause of the ovine disease in this country. The only specific form of ovine abortion which the Committee have met with is due to a vibrionic organism. Full details are given of the morphological and cultural characters of this microbe, which is very like a spirochæte in appearance, though not in its cultural requirements. In the present uncertain state of the classification of spirillar organisms in general, this one is described as a vibrio. It is very important to note that, experimentally, this vibrio may cause abortion in cows as well as in sheep, and that two naturally occurring outbreaks of vibrionic abortion in cows have been met with—one in Ireland and one in Wales.

The alimentary tract appears to be the most common natural channel of infection, and generally, for some time before abortion takes place, there is an infective discharge from the vulva. As might

be expected from the very small interchange of pregnant ewes that goes on, the disease is usually enzootic rather than epizootic in character, not spreading rapidly from farm to farm.

The symptoms are not very distinctive—perhaps a sanious, mucoid vulvar discharge before abortion is the most significant one. Usually abortion takes place at an advanced period of pregnancy. Very often the foetus has died at a much earlier stage, though lambs may be born alive from an infected uterus at or about full time. Often both foetus and membranes are putrid when expelled, and metritis, which may be fatal, is not a rare complication. Post-mortem, in the later stages, the uterus shows œdema and congestion, with an abundant exudate between chorion and uterus. All the uterine contents—exudate, membranes, and foetus—contain the vibrio, and are virulent.

The spread of the disease under natural conditions requires further investigation; but it is certain that an ewe may discharge vibrios from the vagina, and thus be infective, long before showing any signs of impending abortion. It is doubtful whether the ram has much or any importance as a factor in contagion. There is also much still to be learned as to how long the vibrio can live outside the body. It seems to soon lose its pathogenicity when cultivated; and serious outbreaks of the disease do not usually occur on the same farm year after year. But nevertheless there is some evidence that the microbe may exist, saprophytically or otherwise, outside the body of the sheep.

The symptoms, circumstances, post-mortem lesions, and microscopical findings are all of importance in diagnosis. The agglutination test promises to be of practical value here, and the complement fixation test is also being worked upon. The possibilities of immunisation, and of serum and drug treatment are also being investigated, but no great advance has yet been made. The Committee, however, advance various recommendations for prevention—destruction of virulent material, isolation of aborting ewes and disinfection of their genitals, and, last but not least, the avoidance of penning ewes together in close proximity before lambing. So far, the Committee do not consider that legislative measures are applicable to the disease.

Practically, these two publications form the first account we have had of a hitherto unrecognised disease. They cost only a few pence; and every practitioner who is even occasionally concerned with sheep should purchase them. The report itself summarises all that is yet known regarding the disease; the appendix, which, besides its experimental detail, contains much valuable information gathered in the field, will be found even more instructive.

THE R.A.S.E. DEMONSTRATION.

The Report of the experiments at Woburn has been issued, and we reprint an abstract from it on another page. These experiments were not instituted for the information of the veterinary profession, but as confirmatory work by Englishmen in England, to bring the results to the notice of our agriculturists. There are, in several parts of the country, farms and herds which have been cleared of tubercle, and the results at Woburn, when they are brought to the notice of intelligent farmers, must strengthen the hands of those veterinarians who are working in that direction.

THE CONGRESS AND THE PUBLIC.

In a presidential address which we printed last week, appears an appreciation of an indirect result of the International Congress which, so far as we remember, has not hitherto been mentioned at any of the meetings of local Divisions. Mr. Perry said:—"This Veterinary Congress ought, and I think will bring home to the general public, the important position the veterinary surgeon ought to occupy in the country."

The mere fact of the presence of so large a number of men eminent in the profession, and representative of the Governments of many lands, must enlighten many of the public as to the value of the profession to the State.

ABSTRACTS FROM FOREIGN JOURNALS.

THE VAGUS NERVE AND SEA-SICKNESS.

In healthy men, irritations of the vagus nerve by means of physostigmine induce symptoms quite similar to those of sea-sickness. Dr. F. Fischer, of Naueim, states (*Münchener Medizin. Woch.*) that this fact led him to the view that sea-sickness depends upon irritation of the vagus. He therefore attempted to allay this irritation by means of atropine, and obtained brilliant results. Fifty-two sea-sick passengers, most of them very severely affected, were treated with atropine. The drug was administered subcutaneously in doses of 1 milligramme to men, and $\frac{2}{3}$ milligramme to women. The result was that the symptoms of sea-sickness disappeared in a short time, and, although the sea became still more stormy, did not reappear. The theory that sea-sickness depends upon irritation of the vagus is also supported by the fact, attested by numerous clinical observations, that men who already clinically show abnormal sensitiveness of the vagus are especially susceptible to sea-sickness. —(*Berliner Tier. Woch.*)

THE REARING OF GERM-FREE WARM-BLOODED ANIMALS.

Prof. Küster, of Berlin, has published (*Deutsche Medizin. Woch.*) an article concerning this subject, upon which he has worked for some years. Schot-

telins, in opposition to Nuttall and Tierfelder, believed that he had proved it to be impossible for animals to live and thrive in the absence of any germs. He hatched chickens from disinfected eggs in an aseptic incubator, and reared them in a germ-free chamber with sterile air and food. He found that, despite abundant food, they soon died with persistent loss of weight; while control chickens, or sterile chickens which had been intentionally infected with certain microbes, remained alive. Cohendy, who afterwards repeated these experiments, came to the opposite conclusion, finding that a germ-free life was possible to vertebrate animals without any injury to the organism.

Küster took up the question, and chose the goat as his experimental animal, because it seemed to him to be especially suited to the purpose. In the years 1911—1913 he succeeded in overcoming great technical difficulties, and carrying out three experiments. These led him to conclude (1) that it is possible for the larger mammals, especially goats, to be brought into the world aseptically by Cæsarean section, and to be reared by adequate precautions in sterile air upon sterile food, and thus be brought up germ-free, and (2) that the development of these germ-free animals must be regarded as equal to that of normal ones.—*Berliner Tier. Woch.*

[These experiments were carried out upon guinea-pigs a considerable time ago; but I think that Küster is the first to attempt them upon so large an animal as the goat.—*Transl.*

PARALYSIS OF THE QUADRICEPS FEMORIS MUSCLES.

Hugo Marcus, of Wiesbaden, records the case of an Oldenburg mare, six years old, and very well nourished, which suddenly showed symptoms characteristic of azoturia. The animal had been standing in the stable for eight days; and, on the day of the illness, had been taken out for the first time in cool, calm weather. When Marcus saw her she was sweating, and showed paralysis of the hind quarters, especially upon the right side. The left hind limb could still bear some weight, but the right one was quite powerless.

The muscles of the croup were not abnormally hard, and were not sensitive. On the other hand, the muscles of the quadriceps femoris region were extremely tense, as hard as a board, and very sensitive. The breathing and the action of the heart were somewhat accelerated, and the temperature was 100.2 F.

Marcus bled the mare freely, gave arecolin subcutaneously, and drew off the urine with the catheter. The urine showed no striking abnormality. Embrocations were also rubbed into both the croup and the thigh.

After about two hours, the mare had improved so far that the left hind limb could bear weight well, but the condition of the right one remained unaltered. The next day, and during the following week, the right limb remained quite incapable of bearing weight. Various methods of treatment

(embrocations, massage, warm fomentations, electricity, and injections of caffeine) were energetically adopted without the least success. From the second week muscular atrophy set in, and after about four weeks had become excessive, the skin hanging in folds over the atrophied muscles.

The mare was valuable so treatment was persisted with despite the unfavourable symptoms. Electricity was now discontinued, as it seemed to have no effect upon the condition, and its application agitated the mare. Exercise was tried in its place, and the mare was slowly led several times daily. At first, in exercise, the affected limb was trailed with the toe upon the ground almost throughout; but now and then weight was borne for a short moment. At first, also, movement was very fatiguing to the horse, and about ten minutes progression caused violent sweating. The exercise was, however, methodically continued, and had a good effect. Six weeks after the beginning of the attack, the mare could again bear weight well upon the limb when standing. Lameness during progression still persisted, but it was now possible to continue the daily exercise more energetically.

From this time forward the improvement was steady, and the atrophied muscles slowly increased again in size. Three months after the first attack, the mare only showed a slight lameness at the trot. In another three weeks she trotted sound, the affected muscles had quite regained their normal volume, and recovery was complete.—(*Berliner Tier. Woch.*)

CALCAREOUS PRECIPITATIONS IN THE BOVINE BLADDER.

Van der Veen records (*Tydschr. voor Veeartsenijk*) the two following cases. The first was a cow which for some time had shown disturbances in the emission of urine. From time to time micturition took place involuntarily, especially when the animal lay down. Six months previously she had had a laborious parturition, and the urinary troubles had appeared a very few days afterwards.

Vaginal exploration showed that the lower division of the urethral valve was ruptured, thus causing the disappearance of the suburethral diverticulum, so that the organs were similar to those of a mare. The exploring finger easily passed into the bladder, and felt that its posterior portion was covered with a hard crust, and presented a stony consistence.

A calcareous incrustation was diagnosed, and intra-vesical injections of a 5% aqueous solution of hydrochloric acid were advised. The condition improved, but complete recovery did not take place.

The second case was a newly purchased cow, which showed urinary troubles. The urine was emitted in small quantities at a time, and micturition necessitated violent straining. This cow had had a very difficult parturition the year before. As in the preceding case, vaginal exploration showed the disappearance of the suburethral diverticulum. While palpating the floor of the vagina, the author felt a hard body of almost the shape and size of a

hen's egg, which was mobile underneath the membrane. The finger, introduced into the urinary meatus, was able to discern that the surface of this body was smooth except at one point, where a rugged prolongation existed. The case was, therefore, one of vesical calculus, and the author attempted first to extract the calculus whole with the forceps. Fearing, however, that the attempt might cause rupture of the meatus, he soon decided to break up the calculus within the bladder, and extract it in pieces. This was done, and the urinary troubles then rapidly disappeared.

The author thinks that in both these cases the difficult parturition had been the starting point, by causing the penetration of micro-organisms into the bladder. He especially mentions the *micrococcus ureal*, which causes an ammoniacal fermentation with the precipitation of calcium carbonate. It is impossible to explain why the calcium carbonate caused a calcareous incrustation of the mucous membrane in one animal, and formed a calculus in the other.—*Annales de Méd. Vét.*)

THE INFLUENCE OF THE PITUITARY BODY UPON THE KIDNEYS.

Prof. Simmonds, of Hamburg, reviews (*Munchener Mediz. Woch.*) the actions of the internal secretions of the pituitary body. These seem to vary according to which of the three portions of the body—anterior lobe, posterior lobe, or the intermediary portion—is concerned in the secretion. The secretion of the anterior gland-like lobe has a relation with the processes of growth of the skeleton and the connective tissue. In the posterior lobe, consisting of nervous elements, the investigations of B. Fischer show that there seems to be a secretion having an important effect upon tissue change and the genital glands. As to the intermediary portion, Schäfer concluded from animal experiments that the pituitary body exercises an effect upon the vessels and cells of the kidney, and that the posterior lobe and intermediary portion are especially concerned with this function.

Simmonds now brings forward a case showing a connection between pituitary disease and diabetes insipidus in the human subject. The case was one in which a carcinomatous mammary gland had been removed. About two months after the operation, carcinomatous metastases formed in different parts of the body, and at the same time a severe and obstinate polyuria, which certainly had not been present before, set in. Dissection showed carcinomatous degeneration of the posterior lobe of the pituitary body, so that secretion from that lobe was out of the question. The anterior lobe and the intermediary portion were unaffected. As, according to Schäfer, the anterior lobe has certainly no influence upon the secretion of urine, the diabetes insipidus in this case must be attributed to a functional hyper-activity of the intermediary portion.—*Berliner Tier. Woch.*

W. R. C.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

REPORT and RECORD of the Experiments carried out at Woburn for the purpose of demonstrating that by means of isolation it is possible to rear healthy stock from tuberculous parents. [Abstract.]

In arranging a plan for the experiments the Committee had to take account of the circumstances which might prevent the success of any attempt to rear to maturity and free from tuberculosis the progeny of a tuberculous parent. And it may here be said that although the plural word was used in the resolution passed by the Council it was understood by the Committee that what they were desired to demonstrate was the possibility of rearing in a state of health calves of which one parent, viz., the female, was tuberculous. A more prolonged and expensive set of experiments would have been required to prove this possibility with regard to the calves of which both parents were tuberculous, although there is no reason to suppose that the difficulty in breeding and rearing healthy calves from tuberculous cows would be increased in any degree by the fact of the male parents being also diseased.

As it is generally admitted that tuberculosis is a purely contagious disease, resulting from the multiplication of the tubercle bacillus in the bodies of infected animals, what the Committee had really to do was to demonstrate (1) that the bacillus is as a rule not present at the time of birth in the calves of tuberculous cows, and (2) that calves born healthy may be reared in circumstances that prevent infection with tubercle bacilli. It was from the outset clear to the Committee that the experiment might fail to demonstrate either of these things. In the first place it admits of no denial that tuberculous cows sometimes produce tuberculous calves, but it is known that this does not occur once in a hundred times among cows that appear to be healthy. That is to say, the risk of the experiments failing through some of the calves being born tuberculous was very slight, providing the cows selected for the experiment were not suffering from what may be called advanced tuberculosis.

The only real difficulty in the demonstration therefore arose from the risk that the calves might become infected after birth, and the problem was to prevent the access of tubercle bacilli to them. In nature these bacilli come from one source, viz., animals or human beings affected with tuberculosis, and, as regards the bacilli which cause the disease in cattle, the human source may for all practical purposes be left out of account. The arrangements had therefore to aim at making it impossible for tubercle bacilli to reach the calves either directly or indirectly from tuberculous animals, and especially from animals of their own species. The most immediate risk obviously was that the calf might become infected from its mother. To guard against this, each cow at the time of calving was tied up, and as soon as the calf was born it was carried into a building that had not previously been used for cattle, where it was rubbed dry. As soon as possible thereafter it was removed by cart to the calf rearing premises, a mile distant. Further, the man in charge of the calves was kept entirely for this work, and had no contact with other cattle.

As the calf houses here had been to a large extent reconstructed, provided with a new floor, cleansed, disinfected, and whitewashed, it was permissible to assume that there was little or no risk that the calves could become infected by bacilli remaining over from the previous tenancy. The milk on which the calves were fed was obtained from a farm in the neighbourhood, and before use it was raised to a temperature of

not less than 190° Fahr. by immersing the vessels containing it in water which was kept boiling in the copper. Assurance was thus obtained that any bacilli which might have been brought from the cows at the neighbouring farm had been killed.

When milk diet was stopped the calves were kept on two fields which were reserved exclusively for their use, and they were never allowed to come into contact with other animals with the exception of the bull which was put with them to serve the heifers in September, 1912. This bull had passed the tuberculin test before he was brought to the place, and, after arrival, he was again tested, with the same result.

An independent Board of Experts was appointed to conduct post-mortem examinations of the animals as they were slaughtered, consisting of Dr. A. Stanley Griffith, The Field Laboratories, Milton, Cambridge; Mr. James B. Manuel, M.R.C.V.S., 117, Tettenhall Street, Wolverhampton; Mr. W. G. Barnes, M.R.C.V.S., late Superintendent of the Metropolitan Cattle Market, and Mr. James R. Hayhurst, M.R.C.V.S., the present Superintendent of the Cattle Market.

Inasmuch as no evidence of tuberculosis was found in any of the animals after they were slaughtered, these experiments may be held to have demonstrated "that by means of isolation it is possible to rear healthy stock from tuberculous parents."

Although the experiments assumed, and were not intended to prove, the reliability of the tuberculin test when properly carried out, they do add further testimony to its value, for on the assumption that the test is quite untrustworthy there does not appear to be any reasonable explanation of the fact that with one exception (Calf No. XI.) none of the calves reacted, while among 127 apparently healthy cows, 35 (or 28 per cent.) reacted distinctly. The case of calf No. XI. illustrates one of the sources of error in testing animals with tuberculin, viz., an accidental rise of temperature occurring during the period of the test, meaning by "accidental" that the rise was caused by something other than the tuberculin. The facts set forth in this animal's record indicate that it suffered from some temporary illness of which the cause was not determined, and that this illness was responsible for the rise of temperature after the injection of tuberculin on the 18th October, 1912.*

The Committee desire to acknowledge the great assistance given by Lord Rothschild and the late Sir Richard Cooper, Bart., in providing the calves for the demonstration. Their thanks are also due to Sir J. Bowen Bowen-Jones, Bart., the Chairman of the Chemical and Woburn Committee, and to Dr. Voelcker, for their kind co-operation, to Mr. W. H. Hogg, the late Farm Manager, and to Mr. F. C. Atkinson, the present Farm Manager, for their efficient supervision of the animals, and especially to Sir John McFadyean, under whose direction the demonstration has been carried out.

December 9th, 1913.

NORTHBROOK, Chairman.

*[CALF No. XI. Scoured from 18th to 27th April. Castrated on 29th April. Submitted to the subcutaneous tuberculin test on 16th June, 1911 (Table XV.), and did not react.

18th November, 1911, submitted to the subcutaneous, intra-dermic, and ophthalmic tests and did not react (Table XVI.).

18th October, 1912, tested again by subcutaneous, intra-dermic and ophthalmic methods with the result that the temperature rose two degrees Fahr., but there was no reaction to the latter two tests (Table XVIII.). During the three days before the test the temperature on one occasion reached 103.

Although it was not thought probable that the animal was tuberculous it was afterwards isolated, and it was

subsequently found to have a very erratic temperature varying from 103.2 on the 15th November to 106.6 on the 23rd November. On the 24th November it had fallen to 102.2, and from that date till the 29th Nov. it never exceeded 102.4.

29th November, 1912. Tested again by the subcutaneous, intra-dermic, and ophthalmic tests without reaction. The temperatures on that occasion were:—Time of injection 102.4 3rd hour after 102.4 6th 102.9th 102.6 12th 102.7 15th 101.8.

The animal was maintained in isolation until the 24th December, 1912, when it was killed. The post-mortem examination did not reveal any evidence of tuberculous disease.]

The Reports of Boards of Experts as to post-mortem examinations are signed by A. Stanley Griffith, M.D., James B. Manuel, M.R.C.V.S., W. G. Barnes, M.R.C.V.S., and James R. Hayhurst, M.R.C.V.S., D.V.S.M. (Vict.).

The subcutaneous tuberculin test of cows shown in six Tables were carried out by Mr. D. Meadows, M.R.C.V.S. In six Tables by Mr. A. L. Sheather, B.Sc. In one each by Mr. L. Thompson, B.Sc., and Mr. D. A. E. CABOT, M.R.C.V.S.

The tuberculin tests of calves shown in two Tables were carried out by Mr. J. T. Edwards, M.R.C.V.S., and in three by Mr. F. C. Minett, M.R.C.V.S.

[Discussion is deferred until the meeting on February 4th.]

SOUTHERN RHODESIA. REPORT OF THE CHIEF VETERINARY SURGEON FOR THE YEAR 1912. [ABSTRACT].

African Coast Fever. For several years past, our efforts have been directed chiefly to this disease, and it is satisfactory to be able to state that we have succeeded in restricting its spread, and in making good progress towards its eradication. During the year 5 fresh outbreaks occurred, compared with 8 the previous year, and 18 in 1910. The total mortality, which includes animals in infected herds destroyed on showing a rise of temperature, was 505; of these, 409 occurred at one centre, leaving 96 deaths spread over other 9 centres of infection.

In my last report I expressed the opinion that the cattle owner who fenced his farm and dipped his cattle regularly need not fear coast fever; this view has been amply borne out during the year, as evidenced by the reports from various centres where three-day dipping was practised. Apart, however, from coast fever, cattle owners are beginning to realise that they can make no better investment on a farm than a dipping tank. In some cases, not only are the cattle dipped, but every head of domestic stock on the farm, with the result that growth is not retarded, and better condition and health generally are maintained. Another result of regular dipping is the almost entire disappearance of liver disease, scour, etc., in calves. This is especially marked in dairy herds, in which such complaints formerly caused a mortality of up to 90 per cent.

During the early part of the year it was decided to enforce regular dipping in a large area around the infected centres in the Bubi, Bulawayo, Umzingwane and Matabo districts. It was several months before tanks could be erected and arrangements made for all cattle within the defined area. The severe drought also interfered with the operations. At some tanks water was unobtainable; at others cattle were too poor to be immersed once or twice a week, as required. The difficulties are disappearing, and we hope at an early date to have upwards of 30,000 head of cattle regularly dipped in or around the infected centres.

In the Umtali District, one centre of infection exists—Umtali Commonage. During the year two calves

died from coast fever—one in January and the other in March—aged respectively two months and three weeks. In order to locate, if possible, the actual seat of infection, four young animals, from an area on which coast fever has never existed, were placed in the various sheds and paddocks, but without result. The history of this outbreak is interesting, and shows clearly the value of dipping. After several years of freedom from disease, it re-appeared in January, 1910, when a calf died. In the following December another calf succumbed. In both cases the presence of coast fever was confirmed microscopically. Prior to this outbreak, weekly or fortnightly dipping had been regularly practised. When the first case occurred, three-day dipping was resorted to, with the result that, although the cattle were not removed from the infected veld, only four deaths have occurred in two years.

In the Goromonzi (Salisbury) District, in March a calf in a dairy herd on the northern section of the Salisbury Commonage died from coast fever, and in May a two-year-old beast in the same herd contracted the disease and died. Fortunately, weekly dipping had been practised on the Commonage for a considerable period prior to the outbreak. This was changed to three-day dipping as soon as the first case was diagnosed. No further cases have occurred, although the affected herd and those adjoining still remain on their usual pasture.

In the Bulawayo, Umzingwane and Matabo Districts, at the beginning of the year there were sixteen centres of infection. From some of these the cattle had been removed; on the others the three-day system of dipping was carried out. The results have been satisfactory, as cases of disease occurred at three only of these centres.

The disease appeared afresh at four centres, viz., the farms Spitzkop, Inyorka, Alnwick and Collaton. With the exception of Collaton, all were within the fence which surrounded the quarantined area, and were not unexpected because of their proximity to infected veld. At Spitzkop three-day dipping was started immediately the case was discovered in January, since when the herd has remained healthy. At Inyorka the herd was moved in February through a temperature camp to clean veld with a loss of 8 head. The Alnwick outbreak, which occurred in September, was the result of some native cattle straying to the grossly infected veld on Collaton; three animals died within a few days of each other. This herd had been dipped every third day for some time prior to the outbreak, and, needless to say, this process was continued. No further cases occurred.

In February an outbreak was reported on the farm Collaton, outside the fence which encircled the whole of the quarantined areas. The disease was found at several native kraals, and had obviously been in existence for a considerable period. The number of cattle involved was 1,050 head. There was no dipping tank, and no available clean veld for temperature camp purposes. We were compelled, therefore, to keep them on the infected ground, and endeavour to check the further spread of infection by spraying and destroying all animals showing a rise of temperature. We were further handicapped by the fact that all the cattle on the farm had to water at the same pool, and thus several kraals which might otherwise have remained healthy contracted the disease. The results were most unsatisfactory, the total mortality to the 30th June being 352 head. On the 28th June, after various delays, the dipping tank was completed and three-day dipping was started. An immediate and marked improvement occurred, the mortality during the remaining months of the year being as follows:—July, 19 head; August, 20 head; September, 20 head; October, 3 head; November and December, nil—total, 57.

Contagious Pleuro-Pneumonia (Lungsickness). An outbreak occurred in a herd a few miles from Plumtree Station and the southern border. The

animal affected was an aged cow which had been on the farm for over five years; post-mortem examination disclosed undoubted lesions of lungsickness of several weeks' standing. No further cases occurred, and the restrictions were removed after three months. It has not been possible to trace the origin of the infection which caused this outbreak. No case is known to have occurred in Plumtree district for at least twelve years; but in the territories which adjoin us on the west, viz., Bechuanaland Protectorate and the Tati Concession, lungsickness infection has existed for many years past, and within the last three years several outbreaks occurred close to the border, and we have been apprehensive of its re-introduction, especially as cattle are frequently smuggled across the border into the Plumtree district.

Anthrax. Two sporadic outbreaks of anthrax occurred during the year—one amongst pigs on the Ardbennie plots, adjoining Salisbury Commonage; the other amongst cattle on the farm Umganin, about eight miles from Bulawayo. The infected areas were placed in quarantine and all carcasses burned or buried in lime. There is no record of the previous existence of anthrax in Southern Rhodesia, except an outbreak at the old rinderpest inoculation station at Ramaquabane in 1898. It is quite possible, however, that cases have occurred and have not been diagnosed or reported. Its apparent non-existence for so many years may have been the result of the destruction of practically all the cattle in the country by rinderpest in 1896 and the subsequent ravages of coast fever. As a rule anthrax infection exists more or less in patches, and naturally the fewer cattle there are in any given area, the more remote the probability of its manifesting its presence. With the rapid increase in the number of cattle it is quite possible that we shall have occasional outbreaks of this disease in districts hitherto regarded as free from it.

Bovine Plasmoses. Under this heading are included Piroplasmosis or redwater, and Anaplasmosis or gallsickness. Both are enzootic throughout the greater part of Southern Rhodesia. Calves contract the infection of both diseases shortly after birth, and in most cases recover without any apparent symptoms of illness. The immunity conferred by an attack of redwater is of a passive character, and gradually disappears unless the animals are subject to constant re-infection by ticks; in other words, constant tick infestation is necessary to establish the immunity or tolerance conferred by the primary attack. It is evident, therefore, that the destruction of ticks by dipping or other process will result in the disappearance of the immunity. This result has been observed recently at various centres where dipping has been regularly carried out for coast fever purposes. The mortality from redwater not complicated with other affections is not very high. The affected animals respond satisfactorily to treatment, especially to the subcutaneous or intravenous injection of a solution of trypan blue. Unfortunately, however, an attack of redwater is, in the majority of cases, followed at a short interval by one of gallsickness. This disease, exercising its full force on animals whose vitality has been lowered by redwater infection, causes a very heavy mortality, and many of the animals which survive are left in such a debilitated, anæmic condition that complete restoration to health may take one or two seasons. Amongst locally bred stock the rate of mortality from redwater and gallsickness has undoubtedly increased during the last two or three years, more especially amongst calves, the pure or cross progeny of imported breeds. In addition to the contributory causes already indicated, viz., dipping and the greater susceptibility of the finer breeds, there is some reason for stating that the type of gallsickness has increased in

virulence. That this is not entirely because of increased susceptibility would appear from the following observation. During three successive winters young stock from a certain portion of Vryburg district were brought to a farm in Matabeleland. The first season there was practically no mortality; the second season about 10 per cent., and the third about 30 per cent. died from redwater and gallsickness. Amongst cattle imported from the south the rate of mortality has also increased, due chiefly to the extensive practice of dipping as a preventive of coast fever. But apart from this it has been shown experimentally by the Government Veterinary Bacteriologist that gallsickness virus obtained from Pretoria does not render an animal completely immune against natural infection in Rhodesia, the obvious conclusion being that the type of disease which exists here is more virulent than that which exists in the Union.

Anaplasmosis of Sheep. Early in the year the Government Veterinary Bacteriologist discovered the existence of anaplasmosis in sheep, and extended investigation demonstrated its existence in various districts throughout the Territory. Locally the disease is known as "bottle jaw," and was generally regarded as being due to various intestinal parasites. The symptoms observed are those of anæmia and cachexia, and are scarcely distinguishable from those set up by intestinal worms. A common symptom is œdema of the sub-maxillary space, hence the term "bottle jaw." The infection is probably transmitted by ticks; if so, regular dipping would appear to be a suitable preventive measure.

Trypanosomiasis. The trypanosomal diseases transmitted by tsetse-fly to the domestic animals, generally termed "fly struck" or "fly disease," are not of great economic importance from the veterinary point of view, except in so far as it is impossible to farm with stock in the more grossly infested areas. The treatment of affected cattle by the Government Veterinary Bacteriologist was continued with considerable success. In one instance twenty animals were submitted. All of these showed clinical symptoms, and eleven showed trypanosomes in the peripheral blood. Two were retained as control animals. Some received one injection only; others a second treatment after an interval of two days. The trypanosomes disappeared from the peripheral blood soon after treatment, and all the treated animals improved greatly in condition and are still alive. It is not considered desirable to make public at the present stage the nature of the treatment. It was found necessary to suspend the importation of cattle from North-Western Rhodesia because of the existence of disease in the district of Shesheke, and commonly termed "Shesheke sickness of cattle." This disease appears to be a fatal form of Trypanosomiasis which occurs in an area free from tsetse fly, and investigations are now being conducted to determine, if possible, the transmitting agent.

Glanders. It is satisfactory to be able to report that no case of glanders occurred during the year. The practice of testing all horses, mules, and donkeys entering the Territory, which was instituted in 1899 and since consistently carried out, has been of the greatest protection from any serious invasion of the worst and most dangerous of the scourges which affect solipeds. The following animals were tested with mallein on entry:—Horses 848; mules 986; donkeys 2,187. Two horses reacted and were destroyed. Post-mortem examination confirmed the existence of glanders.

Ephemeral Fever—three days' sickness of cattle. Although large numbers of cattle were affected the mortality was practically nil.

Rabies. Outbreaks of rabies occurred in eight districts. The disease is apparently enzootic in the Victoria and adjoining native districts, and the regulations which provide for the chaining up or enclosure of all dogs for a period of not less than six weeks do not appear to be sufficient to eradicate it. Although six weeks is the minimum period prescribed by the regulations, the infected areas or districts are as a rule proclaimed for a period of three months, which is, if considered necessary, extended. In the large native districts which contain enormous numbers of dogs it is a difficult matter to ensure that strict observance of the regulations which is essential to the control of the disease. Although positive evidence is wanting, there is good reason for believing that the disease exists amongst the wild carnivora: if so, its eradication amongst the domestic animals is practically impossible.

The provisions of the Dog Tax Ordinance which is now in force will, by reducing the number of dogs in the country, be of the greatest assistance in reducing the incidence of the disease, and also of tracing the source of infection in fresh outbreaks.

Horse-sickness. The horse-sickness season of 1912 was the lightest on record, not more than a dozen deaths were reported to the Department.

Tuberculosis. Tuberculosis is unknown amongst indigenous cattle, and only one case is recorded amongst cattle imported from the south:—a Cape Peninsula heifer in 1908.

All animals from overseas are tested with tuberculin on arrival. Out of 115 head imported from England and America during the year, nine head reacted to the test and were destroyed. Post-mortem examination in each case disclosed lesions of tuberculosis. Of the nine animals destroyed, five belonged to a consignment of eight bulls imported from England by one of the large ranching companies. These animals were tested with tuberculin in England, but the foot-and-mouth disease regulations prevented their shipment for several months. Unfortunately, the precaution of re-testing them immediately before shipment was not taken.

Rinderpest. For several years rinderpest has existed in the Uganda and East African Protectorates. During the year it appeared at several centres in German East Africa. From information at our disposal it appears that the disease is of a less virulent type, and is not spreading so rapidly as during the former visitation; notwithstanding this, the possibility of its gradually progressing southwards until it reaches this Territory must not be disregarded. Arrangements are being made for a supply of serum, and a conference of the principal veterinary officers of the various states and territories concerned will meet shortly at Bulawayo to consider the best means of preventing its introduction into the areas of their respective administrations, and for controlling it should it be unfortunately introduced.

VETERINARY LABORATORY.

Apart from the routine work undertaken at the laboratory such as the diagnosis of African Coast Fever, rabies, etc., a considerable amount of research work was performed during the year, chiefly in regard to horse-sickness, bovine plasmoses and trypanosomiasis. These and other subjects are fully discussed in the report of the Government Veterinary Bacteriologist, and it is unnecessary to refer at length to them here.

J. M. SINCLAIR, Chief Vety. Surgeon.

R.S.I. Congress, 1914.

The Council of the Royal Sanitary Institute have accepted an invitation from the Mayor and Corporation of Blackpool to hold the next Congress and Exhibition of the Institute in Blackpool, from July 6th to 11th, 1914. The Right Hon. The Earl of Derby, G.C.V.O., P.C., D.L., has consented to act as President.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH].

A meeting was held in the Imperial Hotel, Darlington, on Friday, December 5th, Mr. J. M. Walker, Hartlepool, President, in the chair. There were also present Messrs. G. R. Dudgeon, Sunderland; E. R. Gibson, Seaham Harbour; W. H. Blackburn, South Hetton; J. Wilson, Yarm; W. N. Dobbing, C. G. Hill, F. H. Sanderson, and J. H. Taylor, Darlington.

Visitor: Mr. R. Barker, M.E.C.V.S., Stockton-on-Tees.

It was proposed by Mr. Gibson, seconded by Mr. Dudgeon, and carried, that the minutes of the previous meeting, as they had appeared in *The Veterinary Record*, be taken as read and confirmed.

Correspondence.—A telegram was received from Mr. Peele, regretting that he was unable to be present at the meeting.

An invitation was received from the Royal Sanitary Institute to attend the Congress of the Institute at Blackpool, commencing on July 6th, 1914. It was agreed to leave the matter over until the meeting in March.

A letter was read from Mr. F. W. Garnett, who made an urgent appeal for funds for the Tenth International Veterinary Congress to be held in 1914. After some discussion it was agreed that the Association subscribe £5 5s.

The SECRETARY remarked that probably all the members would have received a letter from Prof. Sir John McFadyean appealing for financial support for the Congress, and it was to be hoped that all the members would subscribe individually in addition to the sum agreed upon.

CLINICAL CASES.

NAVICULAR DISEASE IN A MARE.

Mr. HILL reported an interesting case of navicular disease in a mare twenty-five years old. He showed a photograph of the mare, and the os pedis and navicular bone from each fore foot.

Mr. HILL stated that he had the mare under treatment twelve years ago when he condemned her as being unfit for the work she was then doing, and was of the opinion that she was suffering from navicular disease in both fore feet. She was given to two blacksmiths, who are brothers, and who work in the town, on the understanding that she was not to be sold, and when she became too lame to work she was to be put down. All kinds of shoes were tried, in addition to pads and leathers, and it was found that she went the best in a shoe with a bar across the frog and leathers. The mare worked for years, doing about six miles every day, occasionally she went a long drive once or twice a week, and although she occasionally came out of the stable a little stiff, she was always workably sound. About three years ago she did not go so well during the summer months, so in the month of October her fore shoes were taken off, and she was given a winter's run out at grass. The mare was taken up in March the following year and was so lame that one of the brothers thought that no further treatment was advisable, and was in favour of her being destroyed. The other brother, however, was anxious to give her another trial, and tried a round shoe a little thicker at the heels than at the toe and leathers, and she gradually became workably sound again. When she was turned out again the following winter her fore shoes were allowed to remain on, and she came up alright in the spring, and worked all the summer. Last summer she was taken a driving tour to Whitby and Scarborough, doing on an average twenty-five miles daily, and once she did thirty-two, and beyond being a

little "groggy" on first coming out of the stable, she did all that was required of her.

About two months ago, when being driven near home, she fell suddenly lame on the off fore leg. Her owners were loth to destroy her, and although she became much sounder with rest, if taken out for exercise she became very lame, and as no permanent recovery seemed possible she was destroyed. On making a post-mortem, well marked navicular disease was present in both fore feet, and there was fracture of the navicular bone of the off fore foot. It certainly seemed remarkable that an animal could work so long as this one had done with the navicular bones in the condition they were, and show no contraction of the heels, or anything abnormal in the shape of the feet.

ANTERIOR POLIO MYELITIS IN A DOG.

Mr. HILL said that he had recently a case of this disease in a dachshund dog, which was most interesting. The dog had been quite healthy, and was seen one day "routing" with its nose amongst some rubbish. The next day it appeared to have partial paralysis of its hind quarters; it dragged its toes and could not sit up, or get up stairs. It was certainly not a case of "paraplegia" as one met with it in our patients. The sensory nerves were alright, but not so the motor nerves.

The owner of the dog, who was a medical man, diagnosed the case as one analogous to "spotted fever" in children. It was due to germ infection, the germs gaining access to the system up the nose and affecting the motor cells of the anterior horns of the spinal cord. In children the disease was usually fatal, but in the case recorded the dog had gradually recovered, although the long muscles of the hams were still atrophied but were gradually improving.

"JOHNE'S DISEASE" IN A JERSEY COW.

Mr. HILL stated that he had recently had a Jersey cow suffering from this disease. The owner had had the cow five years, and for the last few months she had gradually been wasting in condition. Diarrhoea was present occasionally, and her appetite was not good, which was unusual in this disease, for as a rule the appetite remained good, in spite of the diarrhoea and wasting. He tested her with tuberculin, but got no reaction, and as she gradually got worse she was destroyed, and the presence of Johne's disease was verified by post-mortem, and confirmed by Prof. M'Fadyean, who very kindly examined and reported on the condition.

Mr. WALKER said that he had come across a few cases of Johne's disease, and what struck him most about these cases was that the dung had a peculiar and distinctive smell about it, and appeared to have bubbles of gas in it.

INFECTIVE FOUL IN CATTLE.

Mr. WILSON asked if any of the members had any experience of infective foul in the feet of cattle? He had recently had eight cases on one farm which made the owner of the cattle afraid he might have foot-and-mouth disease to deal with. There were no mouth symptoms, however, and he had treated the cases by soaking the feet in antiseptic baths and tar bandages, and they were all recovering.

"PROPRIETARY" MEDICINES.

Mr. HILL called attention to the notice which had recently appeared in the journals with reference to the analyses of "quack" medicines and thought it would be a good thing if they, as an Association, sent up samples of such remedies as were used in the district. Some discussion took place respecting this, and it was eventually proposed by Mr. Hill, seconded by Mr. Blackburn, and carried, that the Secretary ascertain what medicines had been sent up for examination with

the object of supplying any which were used in the neighbourhood.

New Members. Mr. A. G. K. BRITTAIN, M.R.C.V.S., Guisbro', was nominated, on the proposition of the Secretary, seconded by Mr. Hill.

Mr. R. BARKER, M.R.C.V.S., Stockton-on-Tees, on the proposition of Mr. Walker, seconded by Mr. Wilson.

NORTH RIDING VETERINARY INSPECTORS.

The HON. SEC. stated that in accordance with instructions received at the last meeting of the Association he had called a meeting of the Inspectors on Sept. 18th at Northallerton. Invitations were sent out to twenty-three inspectors, but only six turned up for the meeting. Mr. Awde, of Stockton, and Mr. Smith, of Stokesley, wrote regretting that they could not be present on account of previous engagements, and Mr. Riley wired that he was prevented from attending. The meeting was therefore most unsatisfactory as regards the attendance, and it certainly looked as if the majority took not the slightest interest in the matter. The meeting formed itself into a "round table conference," and the fees payable to veterinary inspectors were discussed, with the result that it was agreed to leave the amount of fees payable as they were for the present, but Mr. Pratt, the Chief Veterinary Inspector, promised to mention the matter to some of the members of the Executive Committee, and see if any advance would be granted. He pointed out, however, that he could not hold out much hope, as the Order was most unpopular with his Committee. He also thought that with one or two exceptions the fees payable were quite as good as those in the neighbouring county of Durham.

THE LATE MR. WILLIAM HUNTING.

General regret was expressed by the members on the death of Mr. Hunting, and on the proposition of Mr. F. H. Sanderson it was agreed that the Secretary write a letter of condolence and sympathy to Mr. F. and Miss Hunting.

PRESIDENTIAL ADDRESS.

Mr. J. M. WALKER, F.R.C.V.S., Hartlepool.

Gentlemen,—I beg to thank you for the honour you have done me in electing me as your President for the ensuing year. Your decision came as a great surprise to me, and I have grave doubts as to my ability to fill the position as creditably as its importance demands. Any shortcomings on my part I hope you will pardon, and I trust that with the assistance of the Secretary, and your kindly co-operation, I may be enabled to carry out my presidential duties with credit to our Association.

To make a Presidential address is by no means, to me, an easy task. There have been so many addresses lately that it is a difficult matter to introduce a new subject. In the hope that I shall not weary you with my remarks, I propose to just touch upon a few current topics which at the present time and in the future will engage the attention of the veterinary profession.

The Tuberculosis Order, 1913, has now been in operation for some months and has been productive of much good to the profession generally. To my mind the most important result is the fact that it has brought together members of our profession to discuss the working of the Order and the fees relating thereto. In consequence of this the veterinary societies applied to the various local authorities for a higher scale of fees which has now been generally adopted. This in itself shows the advantages to be gained by united action, and emphasises the necessity of the formation of strong local veterinary societies, all acting in co-operation, and conjunction with, the National Society. Every local Society should, therefore, endeavour to increase its membership. What

has been done by united action with regard to the raising of fees by local authorities in particular, shows what might be done to raise fees of practitioners in general, if all were members of a local Society.

The new Veterinary Bill is a measure which has been before the House for some years, and I hope will soon become law. The Royal College is without funds, and therefore unable to give that assistance and protection to the profession which it requires. Besides the annual fee of a guinea I should like to see payment of members of Council and compulsory membership of a local Society. By paying representatives on the Council we would probably secure the best practical and business men, which would be to the best interests of the profession generally.

The Anæsthetics Bill. If this becomes law it will change our procedure in many operations, particularly in country practice, for which higher fees will have to be charged. It may do good as far as putting down quacks is concerned, but they themselves may in time learn to use anæsthetics. It would be better, however, if unqualified persons—no matter what they call themselves—should be prohibited from operating. The option of using an anæsthetic should, in my opinion, be left to the discretion of the practitioner.

Turning to our local affairs, I think we can congratulate ourselves on the past year's work under the worthy presidency of Mr. W. Awde. The attendance has been good, especially at the demonstration, which I am sure was instructive to the members present. Demonstrations are valuable means of obtaining an insight into new methods, and if we desire to keep ourselves posted up to date, they should be as frequent as possible. Specialists on any subject are easily obtained, and I trust that in the future we will avail ourselves of every necessity which arises to arrange a demonstration. If members themselves will bring specimens, or introduce interesting subjects together with data, useful discussions would, in all probability, produce information for our mutual benefit.

Mr. HILL proposed a hearty vote of thanks to the President for his address. This was seconded by Mr. Gibson, and carried unanimously.

GLANDERS.

Mr. G. R. DUDGEON, M.R.C.V.S.

Mr. President and Gentlemen,—When our Secretary wrote asking me to give some remarks on glanders and the mallein test, my first thoughts were to decline; however, I wrote him saying that Mr. Gibson, Seaham Harbour, had more experience of testing than I had, but I had talked the matter over with him, and we had come to the decision that it was the duty of every member to do whatever little he could for his Association, and that I would introduce the subject, and he would give his experience of the test. I am still of the opinion, and I think you will agree with me before I have finished, that my first thoughts were the best.

My first recollection of glanders goes back to the year 1874, and I will tell you why it is so impressed on my mind. In that year an outbreak took place at Sunderland. My father was staying at Barnard Castle, and I had occasion to wire him saying that another case had occurred. I received the following wire from him:—"Home at six, see Hudson, get grave dug on sands, shoot him to-morrow morning." We often wondered what the post office officials would think was going to happen to poor Hudson. Needless to say my father enjoyed the joke, and often used to tell it against himself. At that time I had a fearful dread of the disease, and got it on my mind that I should die of it; however, the dozens of cases I have seen since that time have bred a certain amount of familiarity but not con-

tempt, and I still adopt every precaution against becoming infected, and I must certainly advise all, while dealing with this dreadful disease, that you cannot be too careful.

It is not my intention to give you a set paper on glanders, as I have neither the time nor the ability. As you are all aware, glanders is a disease of great antiquity, and is due to the bacillus mallei, and in the year 1882, I think, the organism was isolated.

Glanders and farcy are one disease, but with different symptoms. In glanders you generally have an enlarged submaxillary gland, which is adherent to the jaw, this enlargement used to be called a "jug," there is a sticky rather opaque discharge from the nostril, and ulceration of the mucous membrane of the nostril. In farcy you have ulceration of the lymphatics, farcy buds, and these may occur at almost any part of the body, but are generally to be found in the inside of the thigh. You also get a corded condition, due to inflamed lymphatics, before the farcy buds appear. A thick leg may be the first symptom, or a wound may be the starting point.

In the year 1891 two Russian veterinary surgeons, Hellmann and Kalning, obtained "mallein" from cultures of the bacilli of glanders. Experiments were then made by continental veterinary surgeons. The French took the matter up very actively, and in 1892, in *The Journal of Comparative Pathology and Therapeutics*, Hunting and M'Fadyean gave the results of certain tests made by them. Now, it is recognised that mallein is a great aid in diagnosis, and what is more, is reliable.

I notice that our Secretary states in the notice of meeting that I have to deal with this disease from the veterinary inspector's point of view. Well, the Glanders and Farcy Order of 1907 is the Order on which veterinary inspectors have to go, and as most of you will be acquainted with it I need not trouble to read it here. The Mines Regulation Bill also provides that every horse, etc., before going into a mine shall be tested with mallein. I know that it was pointed out to the authorities that it would be advisable to have all the animals already in the mines tested first—to my mind a very wise and sensible suggestion.

I will now relate a few cases that have occurred in my district. The first case was in July, 1912, in a new pony which came to a certain colliery. This pony was tested by the veterinary surgeon in charge, and he got a typical reaction. The temperature went up to 105°, and the swelling was 6 inches by 3½ inches. I retested for the local authority, and the temperature again went up to 105°, and the swelling was 5 inches by 5 inches. The pony was slaughtered, and at the post-mortem four veterinary surgeons were present, one representing the owners of the colliery, one representing the owner of the pony, and myself and another representing the local authority. Glanders lesions were found in the lungs, and all agreed that it was a case of glanders.

The next cases occurred in the practice of Mr. Gibson, one of our members. A client of his bought some ponies at a mart as a speculation. He resold them, and Mr. Gibson had to apply the test. When I first saw the first pony tested the local swelling was 6 inches by 4 inches. The pony was destroyed, and lesions were found in the lungs. Three days afterwards Mr. Gibson reported two more ponies as having reacted. I retested these, one's temperature went up to 106°, and the other 105°. Both were destroyed, and lesions found in the lungs. It is interesting to note that the one which had the highest temperature had the least local reaction, and the lesions in the lungs were not so pronounced. I think six ponies were bought, and it is rather remarkable that three of the six should have reacted. I tested the other ponies and got no reaction.

On March 4th this year Mr. Gibson reported a pony affected with farcy. It had been in the pit for eight

years. Farcy buds were present on both hind legs. This pony when tested showed a swelling of 6 inches by 5 inches. It was destroyed on clinical evidence, and lesions were found in the lungs. Sixty-five ponies which had been in contact were tested, but none reacted.

On March 27th last a pony was destroyed on clinical evidence as being affected with glanders and farcy. The hind legs were covered with ulcers, there was discharge from the nostrils, the submaxillary gland was enlarged, and there were ulcers on the mucous membrane of the nostrils. Twenty-one ponies which had been in contact were tested, and three reacted to the test. The first one had a temperature of 102°6', and a swelling 6 inches by 6 inches. The second one had a temperature of 105°2', and a swelling 5 inches by 5 inches. The third one had a temperature of 104°, and a swelling not very marked. On making post-mortems, the lesions in the first two ponies were not very definite, but the liver was very suspicious, and no doubt the disease was in the initial stage. In the third pony lesions were found in the lungs.

On April 25th last I tested two ponies, and the temperatures went up to 102°8' and 103°4'. In the first case there was well marked swelling of over 5 inches by 5 inches, in the other there was only slight swelling, but great soreness. Both cases on post-mortem showed lesions in the lungs.

In June I tested twelve ponies, and got two reactors, and on post-mortem both showed lesions in the lungs. The peculiarity in this case was that I was both "judge and jury," for I had to test for the company, give notice to the local authority, and then test and make post-mortems for the local authority.

I am afraid that I have now wearied you long enough with all the details I have given you. I may say that this year Mr. Gibson and Mr. Blackburn have tested 1317 pit ponies, which I think is a record for the north, and I acted on behalf of the local authority in the matter. Our experience showed us that cases of glanders in a latent condition are present in mines, and shows the necessity that all animals should be tested before going down the mine.

I notice that Russian veterinary surgeons are now saying that the mallein test is not reliable. This may appear rather strange at first sight, in face of the fact that mallein was first produced by two Russian veterinarians, but when we know that glanders exists in Russian ponies which are used here in pits, I think that the statement made about the non-reliability of mallein is obvious. (Applause.)

Mr. GIBSON said that after the very excellent account which Mr. Dudgeon had given, he felt he had very little to say. Prior to the recent outbreak of glanders he had not seen a clinical case of the disease since being in practice in London, seventeen years ago. In those days the mallein test was not recognised by the authorities, and when an outbreak occurred in a stud those presenting clinical symptoms were destroyed, others, which reacted without clinical evidence, were isolated as far as possible, and worked as usual. After settling in practice in the North of England he had not seen a case for sixteen years until March last—the case mentioned by Mr. Dudgeon.

At one of the collieries with which he was connected the horsekeeper drew his attention to a pony with a swollen hind leg. On examination two or three small ulcers were found on the course of the lymphatics. The pony was in good condition, and had been in the mine for eight years. His suspicions were aroused that it might be a case of farcy, and the animal was brought out of the pit and tested with mallein, with the result that there was a typical reaction. This pony was re-

ported to the local authority, and destroyed in due course, and glanders lesions were found in the lungs. The ponies which had been in contact with this case were tested by Mr. Dudgeon on behalf of the local authority, but none of them reacted. On April 1st, in the same mine but in a different stable, another pony showed clinical symptoms and was destroyed; this also was an old pony, and had been in the mine eight or nine years. It is remarkable that both these cases had been underground for so long a time without showing any signs of disease. Twenty-four ponies which had been in contact with this animal were tested by Mr. Dudgeon and three of them reacted and were destroyed.

As a result of these cases he received instructions from the head agent of the colliery company to test the whole of the stock in their three collieries. This was a big undertaking, and Mr. Blackburn very kindly assisted him. The testing could only be carried out at the week-ends, when the ponies were off work from Friday night until Monday morning. The total number of animals tested at the various collieries was 1317, the largest number tested at any one time being 154. It was a tedious business, and they were pretty well tired of it before the whole stock were gone through. The result of the testing in the three collieries was as follows: At Seabam colliery, where the two clinical cases were found, 590 were tested, 11 reacted; at Dawdon colliery 287 were tested, 3 reacted; and at Silksworth colliery 440 were tested, and 2 reacted. These cases of course were all reported in the usual way, and retested on behalf of the local authority before being destroyed.

Mr. BLACKBURN stated that he had assisted Mr. Gibson in the testing of the ponies, and the temperature and local reactions had been very interesting. For instance, in the case of two ponies the temperatures of one at the time of inoculation was 100°8', at the 12th hour it was 105°, and there was a typical local re-action. In the case of the other the temperature at the time of inoculation was 101°5'; at the 12th hour it was 100°4', and never had a rise of temperature, but just a slight soreness of the neck at the seat of inoculation. At the 36th hour, however, there was quite a typical swelling which continued to increase in size. It was therefore not safe to decide about a case until 36 hours after inoculation, for a case like that recorded had occurred twice in his experience.

Mr. HILL proposed that the discussion be deferred until the next meeting, this was seconded by Mr. Wilson and carried.

The members subsequently had tea together in the hotel.

JAMES H. TAYLOR, Hon. Sec.

Burning for Lampas—Conviction.

At Enfield Police Court on Monday, Percy Manning, farrier, of Roebuck Terrace, Enfield Highway, was summoned for burning a horse's mouth with a hot iron. The owner of the animal, David Hale, Hoe Lane, Enfield, a farmer, was summoned for causing it to be so cruelly ill-treated.

Mr. Polhill, prosecuting, stated that on November 16th Hale discovered that his horse was off its food. He sent for Mr. Davis, a veterinary surgeon, but he was unable to attend till next day, when he discovered that the animal had been burnt very severely upon the roof of its mouth. The matter was reported to the Society. The object of the prosecution was to prevent persons like Manning from inflicting unnecessary suffering, and to make persons like Hale understand that it was their duty to obtain the services of properly qualified veterinary surgeons instead of putting cases in the hands of amateurs such as Manning.

Inspector Dodd stated that on November 28th he visited Hale, who admitted to him that he had had the horse burnt for lampas, adding "Yes, it's getting better now. I spoke to Manning as Mr. Davis, a veterinary surgeon, did not come, and he told me that he had the tools at home and that he would cure it as he had cured thousands before." Witness examined the horse, which was about 20 years old and in good bodily condition. Inside the mouth was a large wound, three inches in diameter. Afterwards witness saw Manning, who said "Yes, I did fire it. I fired thousands when I was in the Army, and I hope to fire thousands more. You can do what you like, and you can bring the best veterinary surgeon in front of me. I have got more in my noddle than they have."

Mr. Davis, veterinary surgeon, of Enfield, stated that when he saw the horse he was horrified to find its mouth had been burnt, it had a large raw patch on the roof.

Defendants disagreed with witness's statement of the size of the wound, and Manning produced some instrument.

Mr. Davis said the instrument must have been a larger one than that produced. Witness produced the upper part of a horse's mouth, and gave an illustration of how the operation was performed, and how the effect of burning bars off a horse's mouth was to interfere with the functions of the palate. He had never burnt a horse for lampas, nor seen one done. There was no disease in lampas at all, and it could be cured by using some lotion for the mouth and giving it medicine. Lampas might arise from indigestion, but that was problematical.

The Chairman of the Bench (Mr. H. Trenchard). The Bench would like to know if it was not formerly a custom among farriers and veterinary surgeons to burn horses for this complaint?

Witness: I have never known it done by veterinary surgeons—only among farriers.

Another Magistrate: In the Army didn't old farriers used to do it?—I don't think so.

The defendant Hale stated that Manning told him he could cure the horse in a minute, and that he would like to have as many threepenny pieces as horses he had so treated in the Army. He burnt two bars of the roof three times, and then rubbed salt in. Afterwards the horse started feeding and it "had not left off feeding yet."

Manning said he was in the Army for 21 years and what he did was a custom.

George Manning, a son, stated that the horse never flinched while the operation was in progress.

The Chairman said they had decided it was cruelty to burn a horse's mouth. They recognised Manning had been in the habit of doing it for years without realising the cruelty he was causing. Hale had been led away by Manning. That was the first case of the sort the Bench had had, and they wished it to be known throughout the country that firing for lampas must cease. Defendants would each be fined 10/- and veterinary surgeon's fee.

Motors and Veterinary Students.

Speaking as the guest of the African Club at Maritzburg, Dr. Theiler commented on the great difficulty experienced in getting men for research work. He had been asked to engage men across the water, but he found the motor car was knocking out veterinary science. Where there would be 100 students at the Veterinary College in London, there were now 20. He had found some young South Africans in England, however, who were interested in veterinary science, and it was to these he would look for assistance in research work in South Africa. (Cheers).—*The Friend* (Bloemfontein).

Alleged Cruelty on the Railway: Appeal Allowed.

In the High Court of Justice, Divisional Court, before Mr. Justice Darling, Mr. Justice Rowlatt, and Mr. Justice Atkin, on Saturday, Nov. 22nd. North Staffordshire Railway Company v. Waters—a case stated by the Quarter Sessions of Staffordshire.

Mr. Disturnal, K.C., and Mr. Burne appeared for the appellants; and Mr. Stuart Bevan appeared for the respondent.

On April 9th the Staffordshire Quarter Sessions heard an appeal against a conviction dated March 13th, whereby the appellants were convicted for that on February 5th at the parish of Stafford they did carry by rail certain animals, to wit, 11 cows, which owing to infirmity and fatigue could not be carried without unnecessary suffering during the transit by railway between Uttoxeter and Stafford, contrary to the Animals (Transit and General) Order of 1912 and contrary to the form of the Statute made and provided.

The Quarter Sessions dismissed this appeal, subject to the case being stated.

For the appellants it was contended (1) that Clause 17 of the Order created no offence, but merely applied the penalties provided in the Diseases of Animals Act, 1894, to the offences mentioned in Clauses 1 to 16 of the Order. (2) That the appellants were not the persons in charge of the animals within the meaning of Clause 12, and that that clause did not impose any duty or liability on the railway company, but only on the owner or some one on his behalf tendering the animals for carriage. (3) That guilty knowledge was essential to the offence, and there was no evidence of guilty knowledge on the part of the appellants.

The Quarter Sessions Court held that after the cows were delivered to the appellants for transit, the owners and drover ceased to be, and the appellants became the persons in charge within clause 12, and that the appellants had committed an offence against the Diseases of Animals Act, 1894, as provided by clause 17 of the Order. They further held that though when there was no apparent unfitness in animals offered for transit, the railway company was under no obligation to ascertain whether they were in fact fit, yet when, as in this case, animals tendered for transit were manifestly in bad condition and the company's servants took no steps to see if they could be carried without unnecessary suffering, and unnecessary suffering was in fact caused, the company could be convicted without further proof of knowledge.

The Order in question was an Order of the Board of Agriculture and Fisheries, dated April 22, 1912. Clause 12 was as follows:—"No animal shall be permitted by the owner thereof, or his agent, or any person in charge thereof, to be carried by railway if owing to infirmity, illness, injury, fatigue, or any other cause, it cannot be carried without unnecessary suffering during the intended transit by railway." Clause 17 provided that if anything was done in contravention of any of the provisions of the Order the railway company carrying the animals, and also in certain cases the consignor, each in respect of his own acts or omissions, should be deemed guilty of an offence under the Act of 1894.

Mr. Disturnal, for the appellants, now submitted that the Act and the Order drew a clear distinction between the owner of an animal, or his agent, and the railway company. Railway servants could not be expected to know the condition of animals, though a drover might. Clause 11 said that no cow should be permitted to travel by rail if the calving of the cow during transit was reasonably probable; but how could a railway porter possibly know that? The obligation was evidently intended to be laid on the owner. Mr. Disturnal

referred to other clauses of the Order as bearing out his contention. The Order did create offences by the railway company, but they were quite distinct. A carrier was bound by statute to carry goods offered to him, and technical knowledge could not be assumed against him. He referred to sections 23 and 57 of the Act of 1894.

Mr. Bevan, for the respondent, submitted that the appellants were persons in charge, and that there was a clear offence under clause 17. He referred to section 52 of the Act.

JUDGMENT.

Mr. Justice Darling, after stating the facts, said that to find whether an offence had been committed against the Act it was necessary to look at the Order of the Board of Agriculture. There was no order which definitely said that a railway company must not carry an animal when carriage would cause unnecessary suffering. The justices here convicted for carrying, oblivious of the fact that no clause of the Order prohibited carrying. Clause 12 said that no animal should be permitted to be carried, and to carry was not the same thing as to permit to be carried. It was possible to use language so that carrying was permitting oneself to carry, but it was not to be expected that the Board of Agriculture would use language as if it were a German metaphysician. In his opinion the Order in saying "permit to be carried" did not mean the person actually carrying, nor was the company the person in charge within the Order. The justices had tried to extend the Order in a way which could not be supported; the Board of Agriculture no doubt might have made the company liable, but they had not done so. As to clause 17, he would say nothing about it, as he really did not understand it.

Mr. Justice Rowlatt and Mr. Justice Atkin concurred. Mr. Justice Rowlatt pointing out that clause 17 only forbade carrying when it was in contravention of the Order, so they were thrown back on clause 12 to see if there was any contravention.

The appeal was therefore allowed.—*The Times*.

Cruelty Charge at Hull: Magisterial Comments

Harry Hutchinson, carting agent, of Goodwin Street, Hull, was summoned at Hull Police Court on Tuesday last, for causing a horse to work when in an unfit condition. A rully driver, George Smith, of Rifle Terrace, Walker Street, was summoned for working the horse.

Mr. J. H. Payne prosecuted, and Mr. Williamson defended.

P.C. Tuthill spoke to seeing Smith in charge of the horse in Humber Street. Blood was running down its leg from a wound which was four inches by two inches. Mr. Hutchinson explained that the wound was caused a fortnight previously through the horse getting its foot into the halter and falling in the stable.

Mr. D. R. Sowerby, veterinary surgeon, said he thought the horse was not fit to work. There was a large open wound.

The defendant Hutchinson gave evidence as to the accident to the horse while in the stable. Witness had the animal attended to until he received instructions that he could take it out again. When the horse was taken out the wound was healed.

Mr. E. T. Goodall, veterinary surgeon, Hessle, said he had examined defendant's horse. The skin was not broken, but full of water like a blister. After treatment the wound healed excellently, and he advised Hutchinson to take the horse out. Under the skin the wound was healed. Witness saw the horse on the day

before Mr. Sowerby saw it, and there was no open wound.

His Worship: There is no mistake about this, that one or the other of the veterinary surgeons has committed perjury.

Mr. Arthur Weighton, another veterinary surgeon, also spoke to examining the horse on the day after the previous witness made the examination. He thought the horse was in a fit condition to work, as their would be no pain. He could not see any open wound. The wound which had been there had healed perfectly under a scab.

Mr. Williamson afterwards intimated that he could have called more witnesses, and His Worship said he could do so, as someone was committing perjury.

Before the case was resumed in the afternoon, the Stipendiary Magistrate, together with the parties interested, went outside the Law Courts to examine the animal.

The lad Smith was placed in the witness box. He said he was an office boy in the other defendant's employ. He had never taken the horse out previously. On the morning in question he took the rully out, and the load and the cart would weigh 1 ton 13 cwt. He noticed the wound on the horse's shoulder was a bit white. When he had been in Humber Street about five minutes the officer came up, and witness, in answer to the constable, said he did not know what was the matter with the horse. There was nothing wrong with it. The constable pointed to the place on the horse's shoulder. It was quite dry. The horse was stiff through having stood on the Riverside Quay half-an-hour.

Mr. Payne: Do you swear that there was no blood on the wound?—Yes.

Mr. Payne: The three officers swear there was.

Sergeant Dent said that on November 6th he was in Humber Street with Sergeant Hopkins, when the constable, Tuthill, drew his attention to the horse. He examined the animal, and found that the wound was wet with blood.

Answering Mr. Williamson, witness said the wound could have dried up very quickly, but there would still be a wound. It might have been quite dry when taken out in the morning.

Sergeant Hopkins said he also examined the horse, and saw the open wound. There was blood on it. It would have been impossible for the wound to have healed in less than a week. It was not bleeding.

His Worship, in his decision, said the case presented considerable difficulty. The veterinary surgeons were inconsistent with each other, and the evidence of Mr. Goodall and Mr. Weighton and of Mr. Sowerby was contradictory. That question, however, most serious as it was, was not the first question he had to decide. The question arising was whether there was a wound or not. He was of opinion, on the weight of evidence, that there was a wound, and that Mr. Sowerby was right. As to the contradictory evidence, that was a matter for the police to consider.

His Worship added that he had never known Mr. Sowerby to be the least bit inclined to put a case unfairly. On the other hand, he had often been rather too kindly disposed to defendants. Therefore, when he said there was a wound it carried considerable weight. The case against the boy would be dismissed. The question with regard to Hutchinson was, what was the state of his mind on the morning of November 6th, whether there was a guilty mind. His Worship believed there was, and decided to convict.

A fine of £2 6s. 6d., including costs, was inflicted. An appeal is contemplated.—*Eastern Morning News*.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN SCOTLAND.

At a meeting of the Board of Examiners held in Glasgow and Edinburgh on December 8th for the Written, and on Dec. 10th, 11th, and 12th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:—

GLASGOW COLLEGE.

Mr. J. McI. Galloway | Mr. H. McD. Paul
J. McL. Dawson

EDINBURGH COLLEGE.

Mr. A. W. Carter | Mr. J. B. Russell
E. Sewell

The following passed the Third Examination:—

GLASGOW COLLEGE.

Mr. D. Pollock.

EDINBURGH COLLEGE.

Mr. J. E. Syme | Mr. R. J. Forrest
W. J. Bambridge * | L. Littler

The following passed the Second Examination:—

GLASGOW COLLEGE.

Mr. H. J. Hughes *

EDINBURGH COLLEGE.

Mr. R. L. Creery | Mr. T. M. Martin
J. McAllan | T. A. Shaw

The following passed the First Examination:—

GLASGOW COLLEGE.

Mr. C. W. Corson.

Marked thus * passed with Second Class Honours.

REVIEW.

PRACTICAL BACTERIOLOGY, MICROBIOLOGY AND SERUM THERAPY (Medical and Veterinary), a text book for laboratory use, by Dr. A. BESSON, formerly Director of Bacteriological Laboratories of the Military Hospitals of France, translated and adapted from the fifth French edition by H. J. HUTCHENS, D.S.O., Heath Professor of Comparative Pathology and Bacteriology of the Univ. Durham. Royal 8vo. pp. xxx. + 892 with 416 illustrations, 149 of which are coloured. Cloth, lettered: 36/- net. Longmans, Green and Co., 39 Paternoster Row, London, E.C.

The object of this work is to meet the requirements of the student, and at the same time to act as a work of reference for the more experienced worker. These are objects which are not easy to attain in one book, but the author has succeeded in carrying out his object in a very efficient manner.

The subject matter is considered under seven main heads, viz., General Technique, Pathogenic bacteria, The Parasitic fungi, Pathogenic spirochaetæ, Protozoan parasites, Filtrable viruses, and the Bacteriological examination of water sewage and air.

The chapter devoted to the Theory of the Microscope is extremely useful in view of the tendency on the part of students and of many more advanced bacteriologists to use their microscope simply as a magnifying glass. The book contains a large variety of methods, including many of the more modern ones, and in most cases the author has indicated his preference.

The systematic part deals adequately with some of the less important groups such as the hæmorrhagic septicæmias, the trichophyta and the anærobic gangrene organisms. This makes it more useful as a book of reference than the ordinary students' manual, which usually deals fully with a few types, but dismisses whole groups in a few words.

The chapter devoted to immunity does not profess to give a detailed account of the subject. It is rather too condensed to be of use to the student, and as a whole, lacks clearness. This is especially true of the paragraphs on anaphylaxis, which appear in the section on antitoxins. Exception must be taken to the statement on page 306 that only two other pathogenic organisms present the staining properties characteristic of the tubercle bacillus, namely, the leprosy bacillus and the bacillus of Verruga peruana.

With reference to the serum diagnosis of enteric fever, it is pleasing to note that the author gives prominence to the fact that Grünbaum was the first to utilise the agglutinating properties of the blood of enteric fever patients as a rapid and conclusive method of diagnosis.

In connection with the preparation of tetanus toxin, the author recommends that the culture be incubated at 38° C. for four or five weeks. This is not in accordance with the views held by most bacteriologists. The statement also on page 226, that agglutinins are destroyed by heating at 60° C. in serum does not hold good in every case.

The enormous amount of ground which is covered in a comprehensive manner, the lucid descriptions of technique and results, and the reliable nature of the work as a whole, will render it of the greatest value to veterinarians as a work of reference, and no up-to-date worker can afford to be without it.

J. B. B.

Sale of an Unnerved Horse.

James Carr, jobmaster, of Burgess Hill, sued John Murray, jobmaster, Cross St., Woolwich, for £24 3s. 8d. damages for breach of warranty in respect of the sale of a horse. Defendant claimed to be indemnified by John Ford against the liability in respect of the warranty on the ground that it was made by him on his behalf.

Mr. Joseph appeared for the plaintiff, and Mr. Drake (instructed by Mr. H. E. Thomas) for Murray.

Counsel explained that on July 30th the defendant put up for sale at a repository a horse which was warranted. The conditions of sale provided that a horse unnerved must not be sold with any description which carried a warranty. His client, who wanted a horse for contract work, bought the horse for 14 guineas, but after working a short time it was found to be lame and unnerved, and had to be destroyed.

Several witnesses were called for the plaintiff, and Henry Taylor, F.R.C.V.S., of Hayward's Heath, said he found the horse to be unnerved and only fit to be destroyed.

Mr. Drake submitted that the horse was bought under certain conditions which the plaintiff had not complied with, and therefore had no remedy.

After some argument His Honour intimated that he was against Mr. Drake on the pleas.

Murray said he sent the horse to the repository to be sold for Ford and paid him the purchase money, less commission.

Ford said he did not know the horse was unnerved at the time it was sold. He asked Mr. Murray to sell them because he thought he could make more money than he could. Murray paid him £27 10s. in gold.

His Honour gave judgment for the plaintiff for £17 13s. 8d. with costs payable in 14 days and judg-

ment for defendant against the third party for same amount with costs payable at £1 a month.—*Kentish Independent*.

[This case presented one or two interesting features in the question of warranty. A representative of Aldridge's, who has been with the firm for 15 years, did not recall any similar action, as the unnerving had always been found out within the two days allowed for the trial of horses to ascertain if they did fulfil the warranty.

Counsel for defendant argued that the warranty given, viz., quiet in harness, required that the horse, if he did not comply with the warranty, should be returned before five o'clock on the second day after the sale, failing which he became the property of the purchaser with all errors and faults.

Counsel for plaintiff contended that, as an unnerved horse could not be sold with any description which carried a warranty, there was *no warranty*, and hence no time limit for the return.

The Judge decided that the plaintiff was entitled to succeed.

H. T.]

Cruelty Charge at Llangefni—Dismissed.

At the Llangefni Police Court on Monday, the 15th, Bartholemew Crowley, a cattle dealer, of Cork, was charged by the R.S.P.C.A. with cruelty to ten yearling cattle, by exposing them on the street at Llangefni for five hours.

Inspector Snelling prosecuted for the Society, and Mr. M. E. Nee appeared for the defence.

P.C. Jones said that his attention was drawn to the cattle at 2 p.m. They appeared to suffer from the cold. They had been standing from 10 a.m. He suggested to the owner that he should remove them to a shelter. In reply to Mr. Nee, the witness said the cattle were not kept exactly in the same position, they were in a side street the second time he saw them.

Inspector Snelling said he spoke to the defendant about 2.30 and told him that he should remove the cattle, as they were suffering from the cold. Defendant said he was going shortly after being paid for some other lots he had sold. He brought Mr. Trevor Williams to examine the cattle. They had then been taken to a yard and were eating hay.

Mr. Trevor Williams said he was a member of the Royal College of Veterinary Surgeons. He examined the cattle at 3 o'clock on December 4th. He thought they were suffering from cold.

Mr. Nee: What do you think constituted the cruelty?—Keeping them in the open for five hours without food.

Mr. Nee: But these cattle have never been indoors. Do you suggest that they would be warmer in a field with the gate closed?—Yes, for they could then walk about to keep themselves warm.

But surely there was more shelter in the streets than on the open field?—No, they could shelter beside a bank in a field.

Mr. Nee: But they had here the shelter of the strongest bank in the Kingdom! Do you suggest that the defendant should have bought mackintoshes and umbrellas and held them over the cattle? (Laughter.)

The defendant, Bartholemew Crowley, said that he had been all his life in the cattle trade and had never been interfered with before in this way. The cattle would not look saleable if they suffered to the extent alleged. It was to his interest to keep them in good condition. This lot fetched a good price the following day. They were well fed on pasture and hay during the previous night and up to 10 o'clock.

Inspector Snelling: Was this not the coldest day of the year?—I don't know; I'm not an astronomer.—(Laughter.)

Mr. L. W. Wynn Lloyd, Carnarvon, said he was a member of the R.C.V.S., and an Inspector to the Board of Agriculture and Carnarvonshire C.C. He considered that defendant was not guilty of cruelty. Probably a third of the young cattle in Carnarvonshire were still out. He had practised for some years in Ireland and knew the conditions under which these cattle were reared. He considered them harder than our own.

Inspector Snelling: Do you think they would be as warm on the street as in a field where they walk about to keep themselves warm?—They would probably be warmer when huddled together. It is news to me that an animal walks about in a field to keep himself warm. There is a difference between cruelty and discomfort, and I think you have confused the conditions.

Inspector Snelling: These cattle are surely put in sheds at night in Ireland?—You don't know the Irish sheds, there are degrees of them. In the average case they would only be half in, for it's only half a shed. (Laughter.)

Don't you think that Mr. Williams, having seen the cattle, is able to give a better opinion than you?—He had greater advantages to form one, but not necessarily a better opinion.

The Chairman (Col. Lloyd) announced that the case was dismissed.—*North Wales Observer*.

The Training of Performing Animals.

A conference was held at the offices of the Royal Society for the Prevention of Cruelty to Animals, 105, Jermyn Street, last week, with a view to arriving at a practical solution of the question of cruelty in the training and management of performing animals.

Mr. E. G. Fairholme, honorary secretary of the R.S.P.C.A., presided, and among those present were Mr. Fowler (representing the R.S.P.C.A.), Mr. Charles Gulliver (managing director of the London Theatres of Varieties), Mr. Oscar Barrett (manager of the Empire Theatre, London), the Rev. T. Horne (chaplain of the Showmen's Guild), Mr. James Sanger (circus director), Mr. and Mrs. Fred Ginnett (circus proprietors), Messrs. E. H. and Francis Bostock (proprietors of Bostock's Menageries), Capt. Woodward (owner of performing seals), Professor John Buer (animal trainer), Mr. Wm. Berol (executive, International Artists' Lodge), and Mr. B. Sherek (music-hall agent).

It was unanimously resolved that in future all owners of animal turns should require a licence to be issued by the R.S.P.C.A. as a guarantee to the management and the public that no cruelty is used in the training and management of performing animals.

Foreigners are to furnish certificates through the foreign societies for the prevention of cruelty to animals that no cruelty has been used in the training. Each trainer will be supplied with a book in which full particulars will be stated of all animals carried, also visits of inspectors, paraphernalia used in the training and for performances, treatment by veterinary surgeons, and so forth. Lists of engagements must be provided, and inspection permitted at any time. The managers will give every facility to allow entrance to inspectors, without previous notification, at all hours. Animal trainers convicted of cruelty will be deprived of their licence, have all their engagements cancelled, and be expelled from the artists' organisations. A record will be sent to all the societies for the prevention of cruelty to animals all over the world, making further appearances of the undesirable animal trainer impossible.—*The Times*.

A Successful Experiment.

In September last a six months' old stirk, belonging to Mr. Joseph Dorward, Brandsbank, sustained a compound fracture to one of its hind legs near the joint. A well known veterinary surgeon from Laurencekirk was called and examined the beast, and in due course had the damaged limb placed in stucco. By careful attention the stirk, although slightly weak, is now able to walk, and has the appearance of developing into a sturdy bullock.—*N.B.A.*

"Plain" Cows for the Sausage Trade.

At Clerkenwell Police Court, on Thursday, 18th inst., Herbert Geering, of Burgess Hill, Sussex, was summoned at the instance of the London County Council for permitting to be carried, from Lewes to the Maiden Lane Station of the London and North-Western Railway, a cow with a malignant growth, contrary to Article 12 of the Animals (Transit and General) Order. For the defence it was stated that the cow was purchased like others as "plain" cows, for the London sausage trade, and that the cow was passed by the inspector at the slaughter-house. Mr. Bros imposed a fine of £5, with five guineas costs, subject to the question of revenue which had been raised earlier.—*The Times.*

The Royal Sanitary Institute.

At an Examination for Inspectors of Meat and Other Foods, held in London on Dec. 12th and 13th, 1913, 41 candidates presented themselves. The 19 candidates who were granted certificates included:—

MARCUS STEVENSON, M.R.C.V.S., Holloway, London, N.
E. WHITE WALLIS, Deputy Registrar,
90 Buckingham Palace Rd., London, S.W.

Personal.

Mr. RICHARD ROBERTS, F.R.C.V.S., of Tunbridge Wells, Kent, veterinary inspector to the Board of Agriculture, the borough of Tunbridge Wells, and the Councils of Kent and East Sussex, left net personal estate value £10,127.

Sir WILLIAM PORTAL, Laverstoke House, Hants, was elected President of the Royal Counties Agricultural Society at the annual general meeting held at Basingstoke. Prince Christian, this year's president, in apologising for his absence, said he felt sure that the show next year at Portsmouth would, under Sir William's presidency, prove a success in every respect. It was reported that the annual show would be held on Southsea Common, of which 40 acres had been allotted to the Society, on June 10th, 11th, 12th, and 13th. In compliance with an influential request from Portsmouth a Saturday had this year been included.

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons (Ltd.), official sale agents in England and Wales for Parliamentary papers and Stationery Office publications, have published the following, the prices include postage:—Civil Service Examination Papers for Veterinary Inspector in the Board of Agriculture, Sept., 1913, 6½d.; Epizootic Abortion in Sheep, Report, 2½d.; ditto, Appendix, 6d.; Irish Milk Supply, Appendix to the Final Report, 2s. 2d.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1330.

JANUARY 3, 1914.

VOL. XXVI.

SCHEDULED DISEASE IN 1913.

This week we print the summary of returns of scheduled disease for 1913. On the whole it shows very good progress.

Swine fever, as usual, is the most unsatisfactory feature. It has fallen this year to 2573 outbreaks as against 2920 in 1912, but this is probably merely one of the inexplicable fluctuations which have long been recognised in connection with this disease. We must either acquire new knowledge, or impose much more drastic regulations than heretofore, before any great progress is made with swine fever. New discoveries may enable us to prevent or cure the disease, and so supersede the stamping-out method. Otherwise, unless we choose to retain the disease indefinitely, we shall sooner or later be forced to accept that old saying of Sir George Brown—"Nothing short of cattle plague regulations will stamp out swine fever."

Anthrax continues to steadily decline, but the returns may be deceptive. So long as a local inspector is empowered to make a final negative diagnosis, but is obliged to submit a positive one to the Board for confirmation, there is a danger that some will report doubtful cases as negative. We indicated this unsatisfactory feature in the present Anthrax Order when it was issued, and we see no reason to change our view of it.

Only two outbreaks of Foot-and-mouth disease, both very recent ones, have occurred—a great contrast to last year. The disease is still in Europe, and that we should have had so little speaks well for our regulations.

Glanders is still decreasing, but for two years past its decline has been much less rapid than in the earlier years of the present Glanders Order. There were 533 outbreaks in 1909, 346 in 1910, 209 in 1911, 173 in 1912, and 162 in 1913. The present slow progress is rather puzzling—but, slow though it is, it is nevertheless sure.

Parasitic mange is declining, but is still one of the most prevalent of scheduled diseases. The figures show that legislation was very necessary, and speak well for the present regulations. Sheep-scab, too, continues to show a substantial annual decline; and its present regulations will suffice to eradicate it in time.

Less than a year's work has been done under the Tuberculosis Order, and we reserve this for future reference. Finally, we recall quite a number of animal diseases which are still scheduled, but which never figure in summarised returns. They have disappeared from the country, some many years ago, and some of the diseases specified above will soon follow them—thanks to the work of our profession.

AN INTERESTING CASE OF PSAMMOMA.

Subject.—Aged bay mare. The previous history of the case was, that the mare had been treated two years prior to this admission to hospital, for large abscesses on the off shoulder, probably the result of strangles; also, a little time later, for a severe attack of impaction of the stomach, during which attack delirium lasted for a considerable longer time than is usual.

After the mare was returned to duty she had occasional fits of sulkiness, occurring three or four times yearly, and lasting from two to three days to a fortnight, during which periods she would be entirely off her feed and drink very little water. It sometimes happened that these sulky fits would occur at exercise, and the mare would stop and could not be moved for half-an-hour or more, when she would walk quietly back to the stables.

During this incipient state of the disease, the symptoms were indefinite and beyond a tendency to become hidebound and unthrifty, regaining condition at intervals, nothing could be observed. The mare, in these early stages, was usually very quiet and never attempted to savage anyone, but occasionally attempted to do so latterly, in the advanced stages of the disease.

Temperature remained normal, pulse slow, and when placed in a loose box she used sometimes to stand with her head near a corner, but not for any length of time. After a few months the sulky fits became more frequent, and longer in duration. The mare would stand for hours in one position, the characteristic attitude being with her head near the ground, in or near the corner, all four legs drawn close together under the body, and frequently raising one hind leg off the ground and swinging it backwards and forwards. This would continue for hours and sometimes days at a time. Rigors were frequently noticed.

At other times the mare would walk around the box, generally to the off side.

Another peculiarity was that she would stand quite still with a straw in her mouth, and turn her head and neck in an upward and backward direction towards the near side. This symptom also would be continuous for days at a time.

The pupils remained normal, showing no undue irregularity in size. Nothing else could be observed except the rapid emaciation and hide-bound appearance which now set in. At this stage the patient would eat and drink practically nothing.

Psammoma was now diagnosed, and the mare destroyed by chloroform. Destruction was just-

fied by the post-mortem, which revealed a large psammoma, about the size of a large goose's egg, in the left ventricle of the brain.

Diagnosis was confirmed by microscopical examination.

There was also a small tumour in the right ventricle, the size of a walnut, which unfortunately is not shown in the photograph.

Inasmuch as the symptoms of brain trouble began to make themselves manifest after impaction of the stomach had been diagnosed, I am inclined to think that the symptoms of impaction may possibly have been confused with those of commencing tumour formation.

B. A. JARVIS, Capt. A.V.C.

Khartoum. Dec. 20th.

ACUTE ENDOCARDITIS IN A HORSE.

Recorded by W. H. WILKINSON and J. F. CRAIG.

The subject of this affection was an aged chestnut heavy cart gelding, belonging to a client of Mr. Wilkinson.

History.—Up to the appearance of this disease the gelding had enjoyed a clean bill of health, and had proved a good useful worker. On account of the Dublin strike, the services of the animal were not required, and it was sent out to grass. Early in November it was taken in, preparatory to commencing work again. In a day or two after its return to the stable it began to show serious symptoms, and Mr. Wilkinson attended the patient.

fibrinous deposit about the size of a hazel nut, the right cusp (2) presented one about the size of a walnut, which was attached to a similar deposit on the wall of the right ventricle, the posterior cusp was diffusely thickened. The bicuspid valve was also thickened throughout and very dark in colour. There was on it a slight layer of fibrin covering the cusps towards their free border. The segments of the aortic valve (4) were affected in a similar way: slight fibrinous nodules had formed on the inner surface of two of the cusps, and at the bases of all the segments. The pulmonary semilunar valve was normal. In the lesions small Gram staining diplococci were found in pure culture.

The photograph was taken by Mr. G. E. Haines, R.V.C., Ireland.

Date, November.	6th.	7th.	8th.	9th.	10th.	11th.	12th.	13th.	14th.
Pulse.	—	—	74	72	72	86	84	86-92	died 7 a.m.
Temperature F.	105.2	103.2	103.8	103.2	103.2	102.6	103.8	103.6	

Symptoms.—The condition of the gelding was good, and it fed well. It was, however, very dull, not inclined to move, and unable to work. Oedematous swellings appeared on the limbs. There was no jugular pulse. The pulse was small and frequent, but not irregular. The temperature was raised, and the rise of temperature continued throughout the attack. The temperature and pulse are noted in the accompanying chart.

The cardiac impulse was very marked on the left side, and was evident to a very casual inspection. The heart sounds were exaggerated, and could be heard very distinctly over the upper portion of the chest wall.

The diagnosis of heart disease was made, and the owner informed that the animal might die suddenly.

On the morning of the 14th November the gelding died rather unexpectedly, and the heart was removed and examined later in the day.

Lesions. The right heart was much dilated. A few sub-endocardial hæmorrhages were noted, one about the size of a sixpenny-piece on one papillary muscle in the left ventricle, and another, smaller one, on the septum in the right ventricle. The bicuspid, aortic, semilunar, and tricuspid valves were all affected. In parts they were roughened, especially on the surfaces facing the blood stream. The accompanying photograph—the heart, split open and flattened out, showing the interior—gives an indication of the condition of these valves. In the tricuspid valve the left cusp (1) presented a

ADMINISTRATION OF CHLOROFORM STANDING.

I was very interested in reading Mr. Howard's paper in *The Veterinary Record* on the above subject. I have administered chloroform standing in a good many cases in both horses and mules, and I thoroughly agree with Mr. Howard as to the advantages of the method.

For the past two years, since I have been in this depot, I have administered chloroform standing in very nearly all cases I operated on, and have not had a single accident or death from chloroform. Unfortunately I have not got a record of the number of cases, but it is quite considerable. The average number of stock in this depot, including horses and mules, is about 3500, all ages from six months to six years.

The method I adopt is practically the same as described by Mr. Howard, except that I chloroform outside and hold the horse or mule by means of an ordinary head collar with two ropes attached, one on either side. I use a Carlisle muzzle, excluding air, and start with 3 ozs. for anything over three years of age, under that age I start with 2 to 2½ ozs. It is often necessary to give another ounce before the animal goes down, but if the chloroform is quite fresh 3 ozs. is, as a rule, sufficient, though cases do occur in which one has to give considerably more. I have given 6 and 7 ozs. without any ill effects.

The majority of cases go down perfectly quietly

in four to six minutes, without giving the slightest trouble; but there are some cases in which there is a stage of excitement, and some horses do fight, but even then there is no difficulty in holding them. I have never yet seen a horse get away.

Cases in which there is much excitement I attribute to the chloroform not being fresh. With fresh chloroform and a 3oz. dose, the horse goes under so quickly that there is no time for the stage of excitement. Beyond allowing the animal to walk round if restless, and holding up a fore leg if he is slow in going down, I do not interfere with him and do not put on hobbles till he is on the ground, and then only if the operation is likely to take time. There is no difficulty in putting on hobbles when the animal is down.

During the discussion on Mr. Howard's paper some people seemed to think there was considerable danger in horses rearing up and falling backwards. The danger appears to be more imaginary than real. I must say I have seen a few horses do so, but not immediately the chloroform muzzle was put on, as they were generally partially under, and did not do themselves the slightest harm.

Like Mr. Howard, I am quite convinced that if people try this method of administering chloroform they will find it efficient and safe, and particularly useful with troublesome horses. The method may be objected to on account of taking more time than the ordinary method, but it really does not do so, as it is important to remember that the moment the horse goes down he is in a fit state for surgical operation.

J. W. O'KELLY, Capt. A.V.C.

Remount Depot, Mona, Punjab, India.
10th December, 1913.

THE EFFICACY OF ANTI-TETANIC SERUM.

I read with much interest—and some astonishment—the letter of “Pre-Historic” on immunisation against tetanus, published in your issue of November 29th, 1913.

It has been my fortune, or misfortune, to practise in a tetanus district for more than thirty years. In the pre-antitoxin period I treated my cases over a long series of years and got a few, very few, recoveries under the old methods of treatment. Today I do not see half-a-dozen cases of tetanus yearly in a somewhat active town and country practice. I have taught my clients the value of immunisation, and many of them keep tetanus antitoxin on hand as a staple stable supply, giving a dose to every animal that receives even a trivial injury. I immunise my surgical cases automatically, without consulting the owner, and usually without even mentioning the fact that I have done so. If I castrate a valuable horse he gets a dose as soon as he gets up, and I have never seen a case of tetanus follow immunisation practised within 48 hours of the reception of the injury.

Furthermore, during the past six years I have been more or less closely in touch with the labora-

tory end, and letters of complaint about biological preparations reach my desk from all parts of the United States and Canada. I have never received a single complaint going to show that tetanus followed proper and prompt immunisation.

Now I do not wish to convey the idea that tetanus antitoxin is a specific immunising agent; *it is not*. We may immunise against enough toxin to kill a horse, but can hardly expect the same number of units to protect against an amount of virulent toxin that would kill a dozen horses.

I do, however, want to drive the fact home that if we insist on getting a properly tested and standardised serum, and immunise our surgical cases promptly, we shall cease to worry about the tetanus corner of our graveyard.

I append the American Standard to allow comparison with the requirements existing in England.

“One tenth of a unit neutralises 100 minimum lethal doses of toxin for 350 Gram guinea-pig.”

All tetanus antitoxin must be tested physiologically before it is marketed.

It is possible to thoroughly immunise a horse against the most massive doses of the toxin and find that his serum had little protective value for other animals.

THOMAS B. ROGERS.

Woodbury, New Jersey, U.S.A., Dec. 19.

ADVANCED TUBERCULOSIS IN A TWO-YEAR OLD SHORT HORN BULL. DEATH FROM BRONCHIAL HÆMORRHAGE.

On the night of Friday, December 12th, the Police Inspector of this town, reported a case of suspected tuberculosis in a bull at a farm some six miles from here.

On the morning of the 13th I visited the farm, and found a two-year old short-horn bull. I examined him clinically; found the temperature and pulse normal, breathing accelerated, and a strong harsh cough. I found that he had been blistered on both sides of the chest. I said to the owner “You have had this animal under treatment?” “Yes,” he said, “He has been off and on for the last six weeks under a veterinary surgeon, but on Thursday night last he bursted a blood vessel and bled profusely from both nostrils. I was told by the veterinary surgeon to report the case to the police, which I did.” I explained to him the process of the tuberculin test, and got his written consent to the inoculation. I told him I would put the animal under the test on the morning of the 15th—Sunday intervening. I also told him to keep the animal under strict observation, and to let the upper part of the loose box door open, for if he got another strong fit of coughing and broke a blood vessel, he would bleed to death.

On the Monday morning I again found temperature normal, breathing better, and he was eating well. The owner said “He looks to-day more like his usual self.” I injected the tuberculin at 9 a.m. and said I would visit again at 2 to 3 o'clock p.m.

At 1.30 a messenger came down to tell me that the bull had had a bad fit of coughing and had bled to death.

On the morning of Tuesday I made a post-mortem examination. The left lung was in a very advanced stage of tuberculosis, the right not much better; the only part that I could say had a healthy appearance was the bottom of the right lobe. I found the mediastinum and pericardium studded with miliary tubercles, but to me the most remarkable feature was the condition of the liver. It was twice the usual size, and of a bluish grey colour, and on dissection I found it of a schirrous nature; on the right lobe I found an abscess the size of a hen's egg, and on middle lobe one as large as a walnut. On opening them I found pus of the colour and consistence of cream. I am sorry I did not keep some for microscopical examination.

Since the Order has come into force I have had many cases of tuberculosis with emaciation and of tuberculosis of the udder, but up to the present I have not been able to find the bacilli in milk.

I hope that the day is not far distant when the Hon. Mr. John Burns' Milk and Dairies Bill will be on the Statute-book.

The hue and cry now is Home Rule and Church Disestablishment, but when the Milk and Dairies Bill becomes law, the churchyard and cemetery establishments won't be so well patronised. One thing is very sure, the infant mortality from this disease will be from 40 to 50 per cent less.

About eight or nine years ago I wrote a letter to *The Denbighshire Free Press*, about the bad sanitary condition of some of the dairies and shippens in this part of the country, but I am glad to say that a great improvement has taken place since then.

T. J. SIMPSON, M.R.C.V.S.

Veterinary Inspector for the County of Denbigh,
Fulbrooke, Ruthin, Dec. 29th.

ABSTRACTS FROM FOREIGN JOURNALS

THE INFLUENCE OF MALLEIN INJECTIONS UPON THE DIAGNOSTIC BLOOD TESTS FOR GLANDERS.

Arpad Marcis, as a result of work done at the Royal Hungarian Veterinary High School at Budapest under Prof. Huttyra, has published an article upon this subject. Various workers, Miesoner among them, have already studied the question of whether the subcutaneous mallein test has any influence upon a subsequently performed agglutination or complement fixation test. They have generally agreed that such an influence exists, and that the blood of non-glandered horses, soon after the injection of mallein, develops and for some little time retains agglutinating and complement-fixing substances similar to those found in the blood of glandered horses. Therefore a non-glandered horse, after the injection of mallein, may react to the agglutination and complement-fixation tests like a glandered one. The subject is obviously one of great practical importance, on account of its

bearing upon the reliability of the diagnostic blood tests in horses previously injected with mallein. The author, after careful experiments of his own, has arrived at the following conclusions, which in the main accord with those of previous workers.

(1) The subcutaneous injection of mallein causes the formation in the blood of non-glandered horses, of specific precipitins, agglutinins and complement-fixing amboceptors, such as exist in the blood of glandered horses.

(2) Precipitins appear after three days, agglutinins after from five to seven days, and complement-fixing amboceptors after from six to ten days. They appear in the blood in the same quantity as in the blood of glandered horses.

(3) The quantity of antibodies existing in the blood of malleined animals begins to diminish from two to three weeks after the injection of mallein, and after three months antibodies can no longer be demonstrated.

(4) In horses which have been injected with mallein, the results of serum tests are of no value until at least three months has elapsed since the injection of mallein.—(*Berliner Tier. Woch.*)

INTESTINAL OBSTRUCTION CAUSED BY A DIVERTICULUM OF THE FLOATING COLON.

Moulis and Salenave record (*Rev. Vét.*) the case of a horse which showed violent colic, with manifest symptoms of intestinal obstruction. Purgatives were given both subcutaneously and by the mouth, but all proved useless. The animal was destroyed.

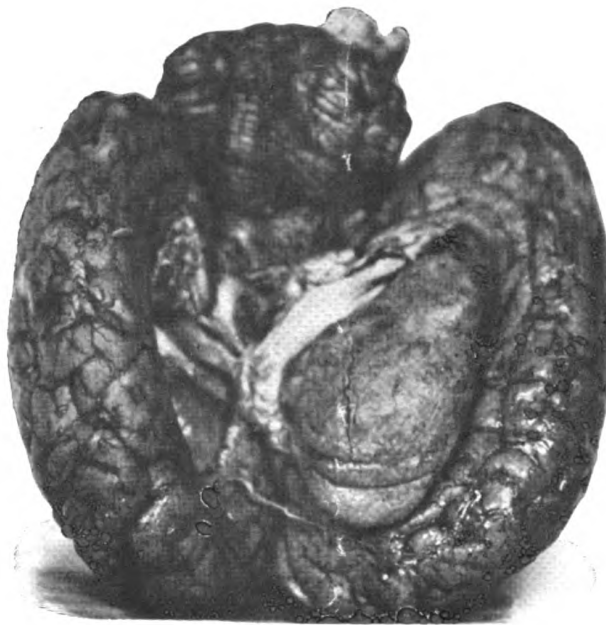

Post-mortem, the cause of the colic was found to be a strangulation of the small colon. The terminal portion of the colon showed a small diverticulum shaped like the finger of a glove, about 1 3/5th inch in length by 3/5th inch in diameter. The diverticulum was in communication with the colon, and was continued by a thin broad cord, which extended over and was inserted upon the rectum. This cord, twisted upon itself, had formed a coil encircling the colon, and by compressing it had caused the intestinal obstruction.—(*Annales de Méd. Vét.*)

W. R. C.

CENTRAL VETERINARY SOCIETY.

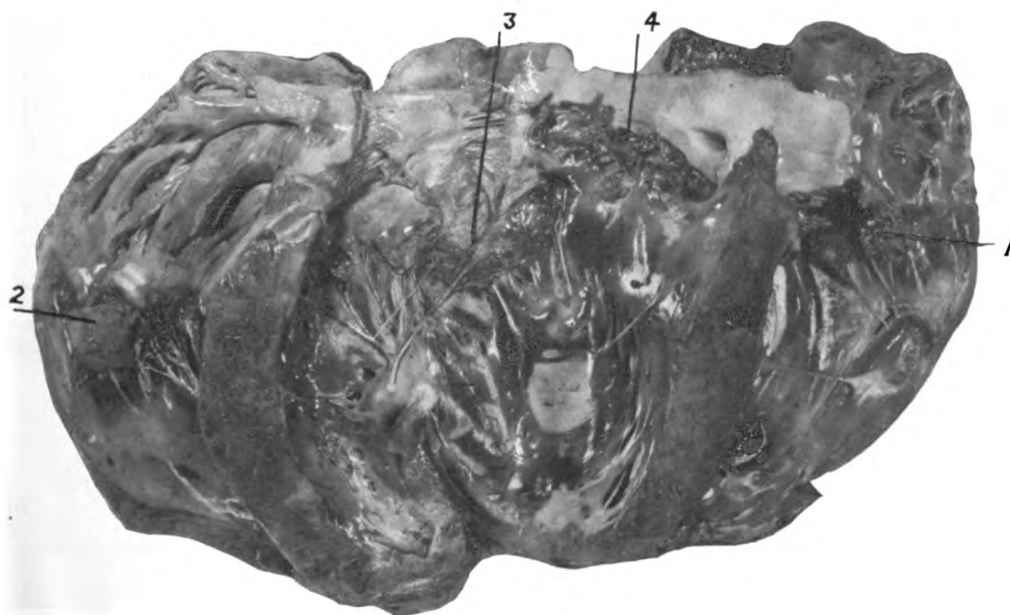

[NATIONAL V.M.A.—SOUTHERN BRANCH].

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, December 4. Prof. G. H. Wooldridge, President, in the chair. Also present:—Messrs. A. Crabb, J. B. Buxton, P. W. D. Smith, J. F. Macdonald, W. R. Davis, Ralph Bennett, N. Almond, R. Gorton, Prof. E. B. Reynolds, M. Cahill, J. W. McIntosh, W. S. King, T. C. Garry, G. H. Livesey, A. E. Willett, C. H. Sheather, H. D. Jones, F. G. Samson, E. L. Stroud, D. Stewart, R. J. Foreman, T. S. Price, R. Eaglesham, L. Auchterlonie, W. R. Clarke, W. Perryman, S. H. Slocock, S. L. Slocock, Col. L. J. Blenkinsop, W. Willis, Sidney Villar, R. Bryden, H. King, F. W. Willett, F. J. Taylor, and Hugh A. MacCormack, Hon. Sec., and sixteen visitors. The minutes of the last meeting were taken as read, and signed.

PSAMMOMA.

Note by Capt. B. A. Jarvis, A.V.C.

ACUTE ENDOCARDITIS IN A HORSE.

Reported by W. H. Wilkinson, M.R.C.V.S., & Prof. J. F. Craig, M.R.C.V.S., Dublin

Correspondence.—The HON. SEC. said he had received a postcard and letter from Prof. Hobday and Mr. J. Willett expressing regret at their inability to be present.

A letter from the President of Tenth International Congress :—

" November 19th, 1913.

Dear Sir,—As you are probably aware, the Tenth International Veterinary Congress will be held in London in August of next year. The suggestion that the meeting place of this Congress should be in Great Britain emanated from our *confrères* on the Continent, and was intended as an honour to the country of John Gamgee, on whose initiative the first Congress of the series was held fifty years ago. A large and representative Organising Committee, of which I have the honour to be Chairman, has been at work for nearly two years, and the arrangements for the scientific work of the Congress are now well advanced. The Committee, however, are not free from anxiety with regard to the provision of the large sum of money that will be required to carry the Congress through in a manner creditable to our country and profession. Judging from the previous congresses, and taking into account the probability that hospitality will have to be extended to an exceptionally large number of foreign members, no less a sum than £4,000 will be required for the purpose. A general appeal to the members of the profession in the country was issued in June, 1912, but in response to that only some 500 members have promised or paid a donation, although the number of members on the Register at present is over 3,400.

I cannot but think that there must be many who could afford to give a donation but who have not done so because they have not realised to what an extent the honour of our profession is pledged to see that the Congress in London shall be no less successful than any of those previously held. It seems to me that this is a matter to which no member who takes a pride in his profession can be indifferent, and I earnestly appeal to you for such a donation as you feel you can afford.

Donations should be addressed to the Hon. Sec., Mr. F. W. Garnett, J.P., M.R.C.V.S., Dalegarth, Windermere.—I am, dear sir, yours faithfully,

J. M'FADYEAN."

The PRESIDENT pointed out, in regard to the Veterinary Congress, that the Society had already done its part, as a Society, and he hoped individual members of the profession would now do their duty.

Mr. LIVESSEY'S SPECIMEN.

The PRESIDENT reminded members that Mr. Livesey brought some specimens of what appeared to be parasites found on the floor of a dog's kennel in moisture that appeared to have been vomited. Members present at the time were unable to identify them. They had since, however, been identified through the agency of Dr. Leiper by Dr. Alcock as the larvæ of the "lesser house-fly." He (Prof. Wooldridge) suggested that they were probably accidental, and had not come from the dog. As Mr. Livesey had subsequently gone into the matter somewhat further he would now call upon him to supplement his previous report.

Mr. LIVESSEY said that since two meetings ago, when he exhibited the specimens referred to, he had further examined the dog. It would be remembered that the specimen was a larval form of some insect, appearing like segmented larvæ with hair-like processes on each segment, and a distinct proboscis. He did not know how it occurred, except that it was found in the dog's bed, in patches of moisture, which might have been from the bowel, or from the stomach. They were found in twos, threes, and larger numbers, and in all stages of development. At that meeting the suggestion was

thrown out—by the President he believed—that these larvæ were entirely accidental, and had been incubated from eggs deposited in the faeces or vomit of the dog. He (Mr. Livesey) was unable at the time to contradict that, but it seemed to him a wrong view, because there were many other dogs on the premises and in the same room, some of which were naturally dirty in their cage or in their runs, yet only in this one dog were the larvæ found. Therefore after the meeting in order to satisfy himself as to where they came from, he gave the dog an emetic on an empty stomach; and he found quantities of the larvæ, in various stages of development, in the resulting mucus. On repeating the emetic a week later he could not find anything. It seemed to prove that on the first occasion the larvæ were inhabiting the dog's stomach. It was not until a month later that he heard the result of the examination which was made by Dr. Leiper. The parasite was new to him (Mr. Livesey) and he did not think it was described among those infesting the dog. The animal was brought from Natal.

Dr. LEIPER said he did not personally examine them. At his Institution there was an unwritten rule that when an entomological specimen came in, it was handed over to the entomologist. After he (the speaker) had ascertained that it was not a worm, he had nothing further to do with it. Dr. Alcock was very interested in the material, and was quite definite in the opinion he gave on the material submitted.

The PRESIDENT said it would be well if the information could be added as to where the dog obtained the material from. It seemed possible that the infestation with these things was accidental, even though it seemed proved that they had inhabited the dog's stomach. If Mr. Livesey still had the dog, it might be well to give it yet another emetic, to see if any were still left. He (the President) could not imagine that they had been brought over by the dog from Natal.

ELECTIONS AND NOMINATIONS.

Messrs. NORMAN THOMPSON, M.R.C.V.S.; B. A. MCGUIRE, M.R.C.V.S.; W. H. ANDERSON, M.R.C.V.S.; and M. G. BYERLEY, F.R.C.V.S., were unanimously elected Fellows of the Society.

Messrs. H. H. MORROW, M.R.C.V.S., 156 High Street, Shadwell, E, and J. R. HAYHURST, M.R.C.V.S., Cattle Market, Islington, N., were nominated, to come up for election at the next meeting.

PRESIDENTIAL ADDRESS.

Prof. G. H. WOOLDRIDGE.

Gentlemen,—It is now two months since you conferred on me the very great honour of electing me your President for the year 1913-14. It would seem superfluous, therefore, and somewhat belated to inflict upon you anything in the nature of a Presidential address, and had I been left to my own inclination in the matter I should certainly have avoided asking you to submit to the ordeal. I am reminded, however, that it has always been the custom, and as I have great respect for ancient custom I must perforce ask you to be patient with me awhile.

When referring to "ancient" customs, however, I must be rather careful, for although the Central Veterinary Society is one of the oldest veterinary societies in the British Isles, we still have some of its founders with us in the persons of Mr. Rowe and Mr. T. Salusbury Price, neither of whom can yet be called "ancient" if appearances and capacity for work are to be the bases on which to form an opinion. The original members are certainly becoming few, the last to leave us being our great friend and adviser, Mr. William Hunting, of whom I had to make sad reference at our last meeting.

One of the most regular attenders, it is very difficult to realise that we shall not have him at our meetings any more, and we shall miss him sitting at his old favourite corner. The name of Hunting will live as long as the veterinary profession exists. As most of you are already aware, a committee has been formed and a fund opened to institute a suitable memorial in his honour, and I venture to express the hope that all the members of this Society will forward some small donation to the fund, in order that the memorial, whatever form it shall take, may be well worthy of the man who did so much so ungrudgingly for all of us.

The Central Veterinary Society is not only one of the oldest, it is also one of the most important of the British veterinary societies, exerting as it does far reaching influence on veterinary politics, and on other matters of veterinary procedure. I have been surprised on more than one occasion when some burning question has been exercising the minds of the profession, and I have asked provincial veterinary surgeons what view was held in their Association, and have been told "we have not discussed it yet, we are waiting to see what line the Central takes first." That is really a wonderful compliment to the Central, and speaks well for the calm deliberation of its members, and the careful guidance of those at the helm in the past. I repeat this not in any spirit of boasting or flattery, but in order that we should realise the important rôle played by the Society, and carefully weigh over our words before giving utterance to them. I trust that the discussions of the Central during my year of office will maintain the same high level, and that we shall lose none of our influence for good in professional matters generally.

In the coming year we are hoping for great things in the veterinary world. First and foremost, there is our Veterinary Surgeons Act Amendment Bill, which we trust will be passed into law. Whatever may have been said of it in its original form, when it also contained clauses designed to protect the profession and the public against various forms of fraudulent practice, it is now a purely domestic Bill, designed only to enable us to raise funds from our own ranks in order to keep the professional flag flying. There is now no reason whatever for external opposition, and it is to be hoped that it may be passed in time to avert the otherwise inevitable bankruptcy of the body corporate.

The next most important event for the coming year is the International Veterinary Congress of London. I do not wish to weary you with repeated appeals for donations to the organising and entertainments fund, but I would point out that the credit of the veterinary profession of the British Isles is pledged in the success of this Congress. The International Congress came into being through the efforts of an Englishman, John Gamgee, and it will be only right and proper that fifty years later the veterinary profession of the United Kingdom shall be able to proclaim within its own domains the most successful of a successful series of International meetings. I understand that up to the present only about one member in six of the profession has sent a donation to the fund. I hope that a goodly proportion of the remaining five-sixths will quickly send along even a small donation, remembering the old Scottish proverb "many a mickle makes a muckle," and so assure the success of the Congress. The benefits of such Congresses are incalculable, for it is only by open and free interchange of views and experiences that progress is possible. We have found that to be the case in local and national affairs as shown in the case of our own Society. It is the same in a far greater degree in International matters.

Only last week I was talking to a veterinary surgeon about this Congress, and he asked bluntly, "What's the good of it?" A little later I found that he did not even belong to his local veterinary society, although he lived

within wonderfully easy access—within a mile—of the usual place of meeting! I enquired the reason, and was asked in return "What's the good of it?" It was quite useless to discuss the matter with a man in that frame of mind, so I gave him up, retorting as the coster did to his pessimistic friend "What's the good of any-fink? Why, nofink!"

I fear there are too many apathetic members of our profession like him, and I wish I could appeal to them to open out a bit, to come out of their shells and mix a little more with their professional brothers. I am sure they would be more than amply repaid, for one takes a much more intelligent interest in any difficult case if one has had an opportunity of discussing it with a professional brother. To some men, however, nothing is any good unless it shows a fair prospect of bringing in an additional guinea at an early date. I am sorry for those men, for I can hardly imagine life to be worth living under such conditions.

The question of the employment of unqualified assistants is an old one, but it was brought to my mind last week by reading an advertisement for one in *The Veterinary Record*. It is a very questionable practice if it is intended to employ the unqualified man to attend to cases professionally. In my opinion such a practice is decidedly unprofessional, and really amounts to "covering," which is regarded as conduct "disgraceful in a professional sense" and liable to severe treatment by the Registration Committee. On the other hand, I can see great uses for such men as infirm attendants, and perhaps dispensers, but they should not be styled "assistants" any more than a farrier who assists one by paring feet for corns or other conditions. The employment of unqualified assistants is mainly responsible for the manufacture of quacks, and often the first man to complain about a quack is the veterinary surgeon who made him—"his own chicken coming home to roost."

A subject that I shall hope to introduce for discussion one day during the year is the question of cruelty to animals. It is a subject we seem to shun for debate, and yet it is a question concerning which we are constantly consulted. The pitiable spectacle of two professional men in the witness box giving evidence on a given case, so absolutely opposed as to be entirely irreconcilable, should certainly be avoidable. It is a matter of small wonder that a magistrate, being a layman in veterinary affairs, feels sometimes bound to disregard entirely such professional evidence. I feel that we ought to regard our professional status more carefully and not run the risk of such adverse comment, which is usually brought about by exaggeration in opposite directions by witnesses on either side, whose zeal to win the case for their respective clients over-rides their discretion. There should not be such divergencies of statement on questions of fact, such as the presence or absence of lameness, but differences of opinion as to the degree of pain caused may quite honestly be held and expressed. There are many aspects of the whole problem, and I think they will well repay an evening's discussion.

Perhaps I may be excused for referring very briefly to the encouraging speech delivered at our annual dinner by Sir Sidney Olivier, the new Permanent Secretary of the Board of Agriculture and Fisheries. Those of us who were privileged to hear him that evening fully recognise that we have a good friend in him, and one who realises the great services which the veterinary profession is rendering, and can render to the community, as regards both the health of the animal population and the health of man, by collaboration with the sister medical profession.

The paper that we are to get to-night from Dr. Leiper is a striking commentary on that point, for since certain parasites of our patients may infect man and cause serious trouble in man, then it behoves us to

tackle our own patients and so assist the medical man in eliminating those risks to the human subject.

I will not detain you any longer now, for, like yourselves, I am anxious to hear Dr. Leiper and to see what he has to show us. In conclusion, I must offer my sincere thanks for the very great honour you have done me in electing me your President during this most important year, and with the hearty co-operation of one and all of you I shall hope to justify the confidence you have reposed in me.

Mr. PERRYMAN proposed a vote of thanks to the President, and expressed his pleasure at seeing Prof. Wooldridge in the chair. He had given a very interesting, though cursory, review of professional work and doings, and had mapped out a course of conduct which he supposed was intended for members to follow in the new year. It was the wish of those members to heartily support the President during his term of office.

Mr. SLOCOCK seconded the vote of thanks, and it was carried.

The PRESIDENT briefly acknowledged the compliment.

CONGRESS OF THE R.S.I. AT EXETER.

Mr. J. W. McINTOSH presented and read his report.

Mr. President and Gentlemen,—I have first of all to thank you for permitting me the opportunity of attending this important Congress as your delegate. It also gave me an introduction to the beauties of Devonshire—a land full of historic interest and glorious scenery. No more suitable centre than its chief town could have been selected wherewith to combine business with pleasure. Exeter is no township of mushroom growth, but a city shrouded in memories of the past, still retaining rights and privileges awarded by England's rulers long ago.

The Congress was received by the Right Worshipful the Mayor of Exeter. The first general meeting was held on July 7th. The Right Hon. Earl Fortescue, K.C.B. (Lord Lieutenant of Devonshire) was installed as President of the Congress, and delivered his inaugural address.

Very suitable accommodation was provided for the meetings in the University College, Guildhall, Victoria Hall, and the Royal Albert Memorial, and excellent arrangements were made for the reception and convenience of members and delegates.

The business of the Congress was divided into four sections and five conferences, all of which were well attended. Such conferences sometimes suffer from being confined to experts, but the gathering at Exeter while providing lavishly for specialists has also had something to say to people in all branches of social activity and may, I think, be heartily congratulated on having produced a number of papers of very great interest. All of these have been published, and in view of this, I shall not occupy much of your time with my remarks.

Conference of Veterinary Inspectors. This conference met on the Wednesday (July 9th) under the genial chairmanship of Prof. Penberthy who, in a very excellent address offered the members his congratulations on the formation of an Association the aim of which was to render their services still more valuable to the community and to obtain for their work the recognition it deserves.

At present there was prejudice amongst stock-owners against the use of tuberculin as a test for tuberculosis. It was certain to his mind that without this, or some other aid, at present unknown, the eradication of tuberculosis would never be accomplished. He looked to the intimate relations of the Veterinary Inspector under the Tuberculosis Order and the owner of infected herds, as a means of establishing confidence in this aid to diagnosis, and an extensiv

adoption in the interests of the stockowner and the community.

The final report of the Royal Commission on Tuberculosis had been received and discussed, with the result, he ventured to think, of deepening the conviction that some portion of the tuberculosis of human beings, especially of infants and young children, owed its existence to tubercle bacilli derived from the lower animals and principally taken into the body with cow's milk and other animal food. The Chancellor of the Exchequer had entered the arena, and, through the National Insurance Act, opened up the avenues of curative treatment.

Demands for the removal of the danger arising from tuberculous animals, though not less insistent on the grounds of being necessary, appeared to have become more moderate and nearer to being practical. He believed that every competent person, who had made a careful study of tuberculosis in cattle and other domesticated animals must be convinced that other and more drastic measures would be required to effect the final elimination of tuberculosis from the live stock of the country. Regarding the Tuberculosis Order, 1913, the stockowner naturally felt that compensation should have been on a more generous scale, and it was to be regretted that it was not frankly admitted that it was, in reality, purely a matter of national health. It was doubtless intended to be complimentary to a "Milk and Dairies Act," and without the latter the Order was incomplete.

Milk and Dairies Bill. Mr. Wm. Ascott, M.R.C.V.S., opened a discussion on the Milk and Dairies Bill. He gave a hearty welcome to the measure, condemned many of the dairies in the South-West of England as a disgrace, but advised that caution should be exercised in putting the Bill in force assuming it became an Act of Parliament, lest by too drastic measures in the first instance, there might be heavy losses to the dairy farmer and considerable reduction in the milk supply of the country.

A good discussion followed, and was taken part in by Dr. Fremantle (Medical Officer Herefordshire C.C.), Mr. A. H. Archer, of Southsea; Mr. G. P. Male, of Reading; Dr. G. H. Garratt, of Cheltenham; Mr. J. A. Dixon, of Leeds; Mr. J. Dunstan, of Liskeard; and myself.

It was generally agreed that a Bill of this kind was very much wanted. One speaker advocated a national service under national regulations, which alone would give inspectors scope and freedom, and thus attract the best men to the work. Another speaker did not know whether the Tuberculosis Order and the Milk and Dairies Bill would work as smoothly together as had been anticipated. He was afraid there might be some over-lapping, and he was of opinion that it would be better if the veterinary inspector under the Tuberculosis Order was also the inspector under the Milk and Dairies Bill. Another speaker said there appeared to be great trepidation in the minds of some people that there was going to be a good deal of friction between the medical officer of health and the veterinary officer, but, personally, he did not see why this should be, if each stuck to his own sphere of work. Nobody would deny that the medical officer should give the final word as to what was fit for the food of man. Another described many cowsheds as "holes of filth." He had no sympathy with those who thought the farmer ought to be compensated on a more liberal scale. He said a man who sold milk from a diseased cow ought not to be rewarded, he ought to get six months instead.

Mr. W. P. STABLEFORTH, F.R.C.V.S., dealt with the subject of "Bovine Tuberculosis." The paper was a highly instructive one, and a discussion followed in which Mr. Bond, Plymouth; Dr. Kerr, Dr. Gamlyn,

Mr. Mole, Mr. Glover, and others took part. Mr. Stableforth expressed disappointment with the discussion, saying it scarcely justified the trouble he had taken in getting up the paper.

Mr. A. H. ARCHER, M.R.C.V.S., read a paper on "The Transmission of Diseases by Animals to Man." He said in the case of domestic, wilful disregard of consequences and gross indifference to the effects produced on their fellow creatures, must be added to the causes operating in the conveyance of diseases from animals to man, or from one human being to another through the medium of an animal. A discussion followed, in which Dr. Garratt, Dr. Webb, Mr. Dixon, Dr. Hay, Dr. Hill, Dr. Barlow, and Mr. Ascott took part.

Dr. HERBERT PECK, of Chesterfield, was to have read a paper on the "Need for Public Abattoirs," but in his absence through ill-health a synopsis of it was given by Dr. Herbert Jones.

In his paper the author directed attention to some well known objections to private slaughterhouses—the main one being the difficulties of inspection. The discussion which followed urged the extreme desirability of public abattoirs, but mentioned some of the difficulties in the way; for instance, compensation to be paid to landlords and tenants of private slaughterhouses and the cost thrown on the rates.

Dr. JONES, in replying to the discussion, said if there was one question which should be treated nationally it was this question of slaughterhouses. The first thing he President of the Local Government Board would have to do was to see that in rural districts slaughterhouses were regulated. The laws with regard to slaughterhouses should be the same all over the country; they must treat it absolutely as a national question.

The PRESIDENT said he should like to have seen some practical suggestion from the Congress which might have been forwarded to Mr. John Burns.

The following resolution was adopted *nem. con.*:—"That the Council of the Royal Sanitary Institute be recommended to bring under the notice of the proper authorities the opinion of this Congress that all private slaughterhouses should be abolished, and that a public abattoir should be established in every sanitary district, or in the case of small districts, in groups of sanitary districts, and that all meat should be inspected on behalf of the local sanitary authorities."

The resolution was carried unanimously, and with this the business of the Conference closed.

In the evening the Mayor and Mayoress gave a conversazione in the University College, which was a brilliant function. The inclement weather prevented the guests from strolling in the grounds adjacent, as originally arranged, but they found plenty to interest them in the various exhibits at the College. They inspected the City Charters, the various Seals, and the City regalia, as well as many other attractions.

The business of the Congress was associated with many delightfully intimate and admirably managed excursions and garden parties, all of which were well attended and thoroughly enjoyed.

I cannot, however, conclude my report without a special reference to the kindly reception given to your delegate by the profession in the South-West of England. After the close of the Veterinary Conference, Mr. Male, of Reading, and myself, were entertained to luncheon. Prof. Penberthy again presided, and after we did full justice to the good things that were laid before us, an extremely pleasant time was spent in moments of mirth regulated by the dial of reason.

Mr. W. R. DAVIS said all would admit that Mr. McIntosh had presented an excellent report of what took place, and he proposed a hearty vote of thanks to him for it.

Mr. PRICE seconded, and it was carried.

Date of next meeting. The HON. SEC. proposed that as the ordinary date of next meeting would fall on New Year's Day, the meeting be held a week later, namely, on Jan. 8th.

Mr. PRICE seconded, and it was agreed to.

THE "HUNTING" MEMORIAL.

The PRESIDENT said he anticipated that Prof. Macqueen or Mr. Henry Gray would have been present to give the meeting some further details about the Hunting Memorial; but he would simply remind members of it, and ask them to subscribe to it.

PARASITES OF DOMESTICATED ANIMALS WHICH INFECT MAN.

By R. T. LEIPER, D.SC., M.B., F.Z.S., Helminthologist to the London School of Tropical Medicine.

When I had the privilege of being present at the meeting of the National Veterinary Medical Association at Carnarvon three years ago, I was much impressed by the fact that nearly all the papers gave rise to eager and sustained discussions. Now, discussions form the most useful part of a scientific society's activity, and it is a source of regret to me that the subject which I present to you to-night is not likely to promote much debate as I confine myself for the most part to explanatory remarks upon the specimens which I have brought to demonstrate.

Prof. Wooldridge, in his presidential remarks, referred to the many interests which the veterinary medical and the medical professions had in common, and I trust it may interest you to learn from my demonstrations how true this is of study of the helminthes or parasitic worms.

My series of parasites of domesticated animals which are known to infect men in various parts of the world comprises twenty-eight species. Some of these forms merely occur in men accidentally or occasionally, and give rise to no special symptoms, others can and do produce active and serious disease. Now to the medical man, and especially to the sanitarian and medical officer of health it is of importance to be able to recognise parasites peculiar to man from those which occur in the domesticated animals, because the measures which would assure the control or elimination of disease in the one case would prove quite ineffectual in the other.

The contrast can be well illustrated by reference to the two diseases known as Ankylostomiasis and Asiatic schistosomiasis. In the former the parasite is peculiar to man, it is spread by the discharge of the worm's eggs in the faeces whence the embryos again infect man through the skin. By a proper disposal of the stools the life-cycle can be broken and the disease gradually got under control. In Asiatic schistosomiasis the eggs similarly pass out in the faeces and infection of man takes place by the skin. But the most stringent measures regarding the disposal of human faeces would not bring about the elimination of the disease from infected areas, for it has been shown that in addition to man, dogs, cats, and cattle in these infected areas also suffer from the disease, and would continue to propagate it. The parasite of Asiatic schistosomiasis when first found in man was named *Schistosoma cattoi*; about the same time the parasite in the disease in cats was named *Schistosoma japonicum*, and it was only later that the two forms were found to be identical, and thus the significance of the dysenteric symptoms in cats and dogs recognised by the medical profession.

I have quoted these two diseases, one an acute anæmia, the other an intractable dysentery to support my contention that the study of the entozoa of man must embrace a knowledge of the entozoa of domesticated animals if the information arrived at is to be of

practical value to the sanitarian. My rôle this evening, however, is that of a naturalist not that of a pathologist or clinician. Of the various forms I shall show, little will be said of their actual significance in the production of disease. A number of my specimens may be better known to some of you than to me. If, then, you find me speaking with an innocent earnestness which amuses you at times you will kindly remember that I am in a position similar to that of the manager of a large works in the West of Scotland whose pride it was to take visitors over the works and explain the various contrivances. On one occasion he had explained with much simplicity the mechanism and uses of certain of his electrical apparatus to a visitor who accompanied one of the directors, he was asked "and what is electricity?" to which he replied, "that you must ask Lord Kelvin." He learned afterwards that his questioner had been Lord Kelvin himself.

I shall now proceed to show the various parasites in their systematic relationships, dealing first with Nematodes, secondly with the Trematodes, and finally with the Cestodes. The majority are smallish forms, and are best seen with the microscope. The microscope has one drawback, that only one person can see the specimen at a time, but I have been fortunate in overcoming this difficulty through the courtesy of Messrs. Leitz, who have enable me to show you my microscopical preparations by means of a microscope specially designed by them, and known as the *Eddinger projection* microscope, which is used either for drawing or for projecting views of actual microscopical slides upon a screen in the same way as an ordinary lantern.

Three of the nematodes are so large, however, that they can best be seen with the naked eye. (1) *Eustrongylus gigas* is a large round worm about a foot in length, as thick as one's littlefinger, and when fresh, of a blood-red colour. It has been found very occasionally in man and occurs normally in the dog. The specimen shown was removed from the kidney of a wild dog from South America, where this parasite would appear to be not uncommon. It lives in the hilum of the kidney, and so disorganises this organ by its presence and growth that, as shown, the kidney eventually becomes merely a thick walled bladder.

(2) *Gigantorhynchus gigas* is also a large thick worm which lives normally in the small intestine, to the wall of which it is firmly attached by the head or rostellum bearing large chitinous hooks. This parasite is a very common one in pigs, and especially in my experience in the pigs in China. It must sometimes be fatal, for I have seen a number of cases similar to the one now exhibited, in which the hook bearing head and anterior part of the body have actually pierced the gut wall, and have been found hanging into the peritoneal cavity. In such cases peritonitis must surely result. No specimens of the adults from man have as yet come into my possession, though several cases are recorded. I have twice diagnosed infections in Chinamen from the discovery of the characteristic wrinkled egg containing the embryo with hooks at one end, in faeces sent for report.

(3) *Echinorhynchus moniliformis*. A smaller form than the previous acanthocephala has been found in man by me in the Sudan. It is a very common parasite in the intestines of rats throughout the tropics, and has as intermediate host the cockroach. The encysted forms are found in the so-called "fat body." As cockroaches are likely eventually to cease entirely to figure in the diet of man we do not need to concern ourselves greatly regarding the spread of this form.

The ankylostomes form a family of small round worms, which give rise to severe and even fatal anæmia when present in numbers. In the tropics, man and dogs and cats suffer severely from its ravages. The species

which produce the disease in man, viz., (4) *A. duodenale* is not exactly the same species as that, viz., (5) *A. caninum* which infest dogs and cats. Quite recently however, Lane, in India, has found a third species (6) *A. ceylanicum* to live in man and cats and dogs.

The ankylostomes afford a very striking example of the manner in which information derived from a study of the parasites of domesticated animals, may supplement or supply valuable information regarding allied parasites in man which could not otherwise have become available owing to experimental difficulties.

In many parts of the tropics, especially in the southern States of the United States of America, and in the tea and rubber plantations of the East, a profound anæmia, due to these ankylostomes, renders the labour problem a constant anxiety and expense. For many years it was thought that infection took place through contamination of food and drink, but Professor Looss, by experiments upon himself and upon dogs has succeeded in establishing that infection in many cases takes place through the skin, from which it follows that protection of the feet of the coolies, by footgear or by tarring, affords a simple means of protection.

I am fortunate in possessing a set of preparations made by Professor Looss himself, which illustrates in a remarkable fashion the various steps of infection of the skin, and the route by which the young embryos pass thence to the intestines. These I now show on the screen. After the eggs, passed in the faeces, have lain outside the body for some hours, and have had access to moisture and oxygen, there develops an embryo which ruptures the shell and then feeds voraciously upon the faecal matter. It grows considerably, and after a few days sheds a sheath, then undergoes metamorphosis, and now makes its way out of the faeces to lie in wait in some moist place, may be for weeks, until it comes in contact with the skin or is swallowed. In this waiting stage we find a second skin has formed, which helps to protect it from dessication. When these sheathed forms come into contact with skin, the warmth causes the little worm to become very active, and the worm punctures the skin, leaving the sheath behind, and enters the fine blood vessels. The section shown illustrates this at various stages. We have worms just half through the cutis, we have others deep in the sweat glands, others, again, in the connective tissue, finally some are seen in the small veins. We now can trace them in our sections as follows: they pass in the venous blood to the right heart, thence to the lungs. Here they break out into the air vesicles, and we see them now free in numbers. Thence they pass up the bronchi in the mucus, up the trachea, and are swallowed, thus reaching the stomach, and finally intestine, where they become adult.

For a long time this extraordinary story was not believed. When Looss had demonstrated it, by means of such preparations as these, it was suggested, particularly by Sambon, that the forms passing up from the lungs were being eliminated, i.e. were side-tracked. Recently, however, Professor Fülleborn, of Hamburg, has demonstrated that this route is a normal one by a series of experiments in which the trachea was cut across, and the upper portion blocked. The worms were thus eliminated from the lungs and were not swallowed. Infection of the dogs did not follow, although the controls showed signs of heavy infection after the application of fewer embryos to the skin. The "lung" forms were similarly eliminated in another series of experiments by the sectioning of the œsophagus. In these dogs also, infection did not result, although the young worms poured from the upper end of the cut œsophagus. Thus it followed that the forms passing through the lung were the actual infecting forms. Professor Looss and others have applied the meta-

morphosed young to their own skin, and have succeeded in infecting themselves in this manner.

Before we leave the Nematodes, I must refer to the occasional occurrence in man of (7) *Toxascaris canis*, (8) *Belascaris mystax*, and (9) *Gnathostoma spinigerum*, parasites that are found in cats and dogs, the former in this country and practically universally, the last named in India and Siam, and (10) *Trichostrongylus instabilis* of sheep.

The guinea-worm (11) *Dracunculus medinensis*, which occurs sometimes in dogs, and very rarely in other domesticated animals, is probably an accidental infection in them of a parasite normally limited to man.

Turning now to the Trematodes. We have occasionally in man the common liver fluke (1) *Fasciola hepatica* which you all know quite well, and another sheep liver fluke which is met with only in the tropics, and, as now shown, is characterised by its long ribbon-like body (2) *Fasciola angusta*. There are also differences in the gut which distinguish this form from *F. hepatica*. While the normal habitat of these flukes is the bile ducts, it is interesting that in man they may wander about in the tissues, and even burst through the skin in abscesses. There is in the Hunterian Museum a pretty preparation of a young *Fasciola hepatica*, removed from behind a man's ear, and I have heard of specimens of *F. angusta* discharging in abscesses on the legs. Another liver fluke of sheep (3) the distoma lanceolatum or *Dicrocoelium lanceolatum* has also been recorded in man, while in a recent letter Dr. J. Bell, of Hong Kong, informs me that he has once seen specimens of (4) *Eurytrema pancreaticum*, which in enormous numbers almost occludes the pancreatic duct of cattle in China. It appears to be limited in its distribution to the far East. We pass now from the parasites of herbivores to those of carnivores. The cat and dog each provide a species of *Opisthorchis*:—(5) *Opisthorchis felinus* common in cats in Eastern Europe is recognised as the same species as *Opisthorchis sibiricum*, which is said to be present in 4 per cent. of persons examined at Tomsk, in Siberia; while (6) *Opisthorchis novorei*, which infects 25 per cent. of the dogs in Lahore, has also been found in a few Mahomedans in India.

In Asia in the cat, dog, and pig, an extraordinary pea-like fluke inhabits the tissues of the lungs. It is believed to be identical with the (7) *Paragonimus westermanii*, which in certain districts of China, Formosa, Corea, and Japan give rise in man to a chronic cough, a rusty sputum, and clinical signs resembling consumption. This disease is recognised by the finding of the large brown eggs of the fluke in the sputum. A piece of lung showing the little parasites in pairs in the tumours, and a slide illustrating the eggs in the sputum are now shown.

Another common parasite of man in the far East is (8) *Clonorchis sinensis*, and this also is found quite frequently in the dog, cat, and pig. It is like the *Opisthorchis novorei*, but the testes are branched instead of being lobed. It lives in the bile ducts, and is contracted from eating infected fresh water fish.

We all know what a gross feeder the Chinese pig is said to be, and this view obtains additional support from the number of important parasites it is found to harbour. The pig shares with man a fluke called (9) *Fasciolopsis buski*, which measures 2 to 3 inches in length, and $\frac{1}{4}$ to 1 inch in breadth. This form again is limited to the far East.

Before leaving the Distomes or Fasciolidae we have to mention two tiny flukes that have only come into prominence during the past six months. These are (10) *Yokogawa yokogawa* and (11) *Heterophyes heterophyes*. They are widespread in China, Formosa, Japan, and Corea, and when present occur in very large numbers. The mature specimens of the former are not more than

1 mm. in length, and the latter range up to 2 mm. They live in the small intestine.

Yokogawa is remarkable in that the ventral sucker is replaced by a muscular ring around the genital pore, while *Heterophyes* is characterised by an armature of antler-like spines surrounding the genital pore, which resembles and lies alongside the large well-developed ventral sucker. In four patients from China and Japan I recently found numbers of this latter fluke, and at a post-mortem in one case collected no less than 4,000 worms. These are now shown, as also a specimen from a dog in Formosa.

Turning now to the Amphistomes, which are represented in the Herbivores especially by a large number of species, we have to notice only one form, viz., (12) *Gastrophilus hominis*. This parasite is often found in the intestines of man in Eastern India, and for a long time it was wrongly supposed that it was a normal parasite of the horse. From the specimen of *Gastrophilus sonsinoi* shown it is obvious that two important anatomical features differentiate these two forms (a) in *G. hominis* the genital pore is on the anterior cone-like neck; in *G. sonsinoi* it is on the ventral disc; (b) in *G. hominis* the surface of the disc is smooth; in *G. sonsinoi* it is studded with papillae. A second species viz., *G. secundus* has been found in the horse, but it retains the same differential characters.

Quite recently *G. hominis* has been found in 5 per cent. of the pigs in Indo-China, so we have to blame the pig once more for acting as a carrier of parasites inimical to man.

The Schistosomidae, like the Amphistomidae, contribute one species which infects equally man and domesticated animals. (13) *Schistosoma japonicum* lives in the venous, and especially portal system of man, dogs, cats, and cattle. The symptoms, which takes the form of an intractable dysentery, are due to the erosion of the mucous membrane of the intestine caused by the hard eggs of the worm which slowly work their way through the tissues from the vessels in which they are laid, to the lumen of the gut.

The Schistosomes, or Bilharzia worms, form a very small section of the parasitic worms of man, but by their wide distribution and the serious and often permanent invaliding they entail, they would suffice alone to place the study of Helminthology in the minimum curriculum of tropical sanitation.

As regards the life history of these various flukes it may be said that much remains unknown, but what we do know points to the conclusion that the development of the various species follows essentially along those lines so admirably elucidated by Thomas in the case of the liver fluke.

The differences that will be found will probably lie in the manner in which the final or cercarial stage eventually reaches the body of the final host. Thus in *F. hepatica* the cercaria encysts free upon grass, and is then swallowed, while in *Yokogawa* and in *Opisthorchis* the cercaria encyst in the flesh of edible fresh water fish.

Of cestodes we have two important and several accidental infections to which reference must be made. The important forms in my opinion are those which may develop their cystic or larval stage in the tissues of man, and so leading to grave functional disorders. You probably know too well the gross changes that result from the development of hydatids. These changes occur in man also and have not infrequently a fatal issue.

You know, too, the significance of *Cysticercus cellulosae* in pork as the origin of the tapeworm *Taenia solium*, of *C. bovis* in cattle as the early stage of *Taenia saginata*, and of the plerocercoid of fish which becomes the *Dibothriocephalus latus*. I refer to them all merely to direct your attention to this one point that the infection of a man with *Taenia solium* may have a much more sinister

effect than the vague anæmia and mental disturbance which follow upon infection with an adult tapeworm such as *T. saginata* (= *T. mediocanellata*) or *Bothriocephalus latus*. Man can function for *Tænia solium* as intermediate host as well as final or definite host. That is, he can directly infect himself with cysts by the contamination of food with cestode eggs from his own faeces. It happens that these cysts not only develop in his muscles but not infrequently lodge in the brain and may cause by their growth an incurable insanity. It behoves the physician, therefore, to deal promptly and rigorously with an intestinal tapeworm of the species *Tænia solium*.

Of little practical importance are infections of man with *Dipylidium caninum* of the cat and dog, and with *Hymenolepis nana* and *Hymenolepis diminuta* of rats and mice. The interest lies in the fact that fleas are the intermediate hosts, and as these species are commonly found amongst children it is legitimate to suppose that infection takes place through the drowning of the fleas in fluid food such as milk, etc.

I conclude my demonstration by showing sections of the brain, lungs, and heart of a man who died in Hamburg from a somatic infection with a larval tapeworm probably *Sparganum prolifer*. This larval form is peculiar in that it continues to grow and gives off branches so that in this case the whole body seemed literally writhing with a hydra-like tapeworm. We do not know the adult form of these *sparganum* worms, but they are related apparently to the *Bothriocephalus* group. Recently the species or a closely allied form has been detected in the pig, and it is to be hoped that we may have here a means of ascertaining in the future the sig-

nificance and origin of these extraordinary vegetative parasites.

The PRESIDENT said he was sure all the members would feel much indebted to Dr. Leiper for the admirable address, and his wonderful exhibition of specimens. He felt sure Dr. Leiper would not expect the Society to discuss the matter in the usual way, especially as the collection was practically unique. It was particularly instructive to see the ankylostomes actually in the skin and lung tissues finding their way to their predilection seats. He believed he recognised one specimen—*eustrongylus gigas*—as from one of his own patients which came from the kidney of a carnivore at the Zoo. [Dr. Leiper: Yes]. He had not diagnosed it during life. The meeting would no doubt have been interested to see a specimen of trichinosis if the lecturer could have shown one. He could not sufficiently express his own gratification for the splendid demonstration.

Dr. LEIPER: The specimen of *Eustrongylus gigas* shown was, as the President supposed, derived from a dog which had died in the Zoological Gardens. A number of forms of which I had not time to deal have, perforce, been passed over. *Trichina spiralis* seemed so familiar, and as I had nothing new to say about it I passed it over. I may mention, however, that I had hoped to show you the adult forms, but was unable to make in time sufficiently satisfactory preparations for exhibit.

To the query regarding the infection of sheep between the winter frosts and the commencing summer, I may say that I have no specific information. If I may generalise somewhat, however, I might add that it is

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

probable that a certain amount of infection might take place during the winter and spring (a) from encysted cercaria not destroyed, (b) from cercaria set free during the winter or spring from snails infected during the previous summer. Although cold always inhibits developmental processes, it does not necessarily destroy larval stages—they merely remain checked for the time being.

It is unlikely that fresh infections of each year are derived solely from eggs, and are not due in part to carrying over of redia and cercaria in the bodies of the snails. I did no experimental work bearing upon this particular point when I was following the development of *F. hepatica* in *Limnasa truncatula*.

After the Fellows had examined with great interest the specimens exhibited by Dr. Leiper,

The PRESIDENT formally proposed a very hearty vote of thanks to Dr. Leiper for his demonstration, and to Mr. Charlton (of Messrs. Leitz) for so kindly officiating at the Edrigger apparatus, which so enormously added to the interest of the lecture.

Mr. S. SLOCOCK seconded, and it was carried with acclamation.

Dr. LEIPER and Mr. Charlton briefly acknowledged the vote of thanks, and said it had given them great pleasure to be there, and hoped they would have another opportunity sometime in the future.

A vote of thanks to the President terminated the proceedings.

HUGH A MACCORMACK Hon. Sec.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, AUG. 3—8, 1914.

In addition to the list of donations to the Organising Funds of the Congress which was dated November 22nd, and was published in *The Veterinary Record* of November 29th, I have received the following sums, either promised or paid.

My attention has been called to the following errors which appeared in my last list: Wharam, S., £15 paid should read £15 15s., and Over, R. and H., should read Alf. and R. H. Over. In my list published in *The Record* of May 3rd, 1913, Wartnaby, Geo., £5 5s. should read Wartnaby and Sadler, £5 5s.

I again appeal to all who have not yet sent a donation to kindly inform me at an early date of the sum they intend to give, by so doing they will greatly assist the Committee in the anxious work of making the Congress financially a success, and I now make a special request to all those who have promised a donation, to kindly assist me by forwarding it as soon as possible.

Those names marked with an * in the present list are donors other than veterinary surgeons.

FRANK W. GARNETT, Hon. Treas.

Dalegarth, Windermere.

Slaughter of Calves.

At a meeting of the Council of the Central and Associated Chambers of Agriculture, following the annual meeting, the report from the Slaughter of Calves Committee was read. It included the following:—

"Of the calves slaughtered when but a few days old, many no doubt would not have been worth rearing as stores. It is feared that in the neighbourhood of the large industrial towns many of the better bred calves are killed when only a few days old, which, if saved, would have proved useful beasts for feeding or dairy purposes.

Your Committee are of opinion that it is mainly a question of supply and demand, and that legislative action is not to be recommended. Dairy farmers, with few exceptions, lack accommodation to rear their own calves, which have therefore to be sold at the first available market, and for the purpose for which they will fetch the highest price. Your Committee are informed that many of the calves slaughtered at a very early age are bought at low prices owing to a temporary shortness of milk, or to other causes resulting in local demand for calves being poor at the time; and they feel that many difficulties and hardships would arise from any attempt to curtail the free sale of calves of any age.

On the other hand, they are of opinion that in other districts a difficulty is being experienced in getting a sufficient number of calves for rearing purposes.

They recommend the following suggestions for the consideration of the Associated Chambers and stock farmers generally:—

(a) That good bulls only should be used.

(b) That a register should be kept of all dairy cows and their produce, the latter to be ear-marked for future identification.

(c) That means should be organised for bringing the rearers—and especially those in non-dairy districts—into touch with the dairy farmers, so that the former might be enabled to buy calves from good class cows, the heifers of which they could sell again as "down-calvers." Your Committee believe that such transactions would prove mutually satisfactory to the rearer and the dairy farmer, the former being assured of a good market for his "down-calvers," and the dairy farmer—besides having an incentive (which he has not at present) to breed good stock—being enabled to fill his byres with cows which he knows have been bred from good milk producers.

Your Committee are of opinion that some such steps as are here suggested, will prove necessary if the quality and quantity of the dairy cows in the country are to be maintained."

Mr. W. A. Haviland (Chairman of the Committee) proposed the adoption of the report, and that it should be sent down to the various local Chambers for discussion.

This was agreed to without discussion. The subject will come up again for consideration at the next meeting, to be held on Feb. 3rd.

The Sale of Milk.

The report of the prevention of Fraud Committee, presented at the meeting of the Council of the Central and Associated Chambers of Agriculture on Dec. 10th, draws attention to the Sale of Food and Drugs Bill (No. 309), introduced by the President of the Local Government Board on August 6th last, and recommends that it be strenuously opposed on the ground that it will enable the Local Government Board to make regulations in the supposed interest of the consumer which would entirely alter the Sale of Food and Drugs Acts in a manner disastrous to important branches of agriculture. In the case of Milk, for instance, if the Bill becomes law the Board may make a regulation defining milk as a fluid containing, *inter alia*, 3 per cent. of butter-fat. The seller of genuine milk will then be liable to a penalty of £20 every time he sells milk which happens to contain less than 3 per cent. of fat, and it will be no defence to prove that the milk is genuine. If the Board decide to fix the limit at 3.25 per cent. of butter-fat, or even higher, there is nothing in the Bill to prevent them doing so. Such a regulation would be contrary to the principle for which the farmers of Great Britain have been contending for many years past—that milk which is of poor quality as regards butter-fat, but still is as it comes from a healthy cow—shall not be treated as adulterated. It would displace the Sale of Milk Regulations, 1901, issued by the Board of Agriculture, and undo all the efforts made by the chambers and agriculturists generally to induce local authorities to work under the Sale of Food and Drugs Acts and the Milk Regulations, with the object of preventing adulteration, instead of using these Acts to prevent the sale of milk of poor quality.

Under the Bill the Board may also define butter as an article containing not more than 16 per cent. of moisture. Under the existing law farmers' butter containing more than 16 per cent. (as it often does) is presumed to be adulterated, but he still has the chance of contesting the presumption by showing that he used proper precautions to prevent an excess of water in his butter. The fact that a farmer has this defence prevents officials

of local authorities from instituting proceedings recklessly in cases of excess water in farmers' butter. Under such a regulation as it is open for the Local Government Board to make, the farmers will have no such opportunity. Such a regulation would also annul many provisions of the Butter Act, 1907, which were purposely introduced into that Act in order that a proper distinction might be maintained as regards excess of water between factory and farmhouse butter. This Bill now proposes to give power to a Government department to do by regulation what Parliament has refused to do by legislation.—*Farm and Home*.

Banquet to Mr. T. D. Young, M.R.C.V.S.

The banquet offered by Dr. Suarez, Director-General of Live Stock, to Mr. Dunlop Young, Chief of the Veterinary Inspection, Department of the London Corporation, on the occasion of his return to England, after making a tour of inspection of the cold storages and breeding establishments of the Republic, took place at the Savoy Hotel, Buenos Ayres, on 20th November.

In his observations at the dinner, Dr. Suarez said the Ministry of Agriculture, wishing to prove its strong belief in the application and constant improvement of the sanitary regulations in meat factories, decided to submit their practice to the examination and criticism of the chief entrusted with the duty to inspect and to decide as to the admission or rejection of these products on the London Central Markets. That was the origin and the reason for the invitation to Mr. Dunlop Young to visit the country and to investigate, with full liberty of criticising in every detail, the method in which meat intended for export was prepared. The Minister of Agriculture wished that he should have the greatest facilities for travelling in the country, so that he might be able to see the stock breeding industry in its real surroundings, and then frankly tell us afterwards what good and faulty points he found, so as to persist in the former and correct the latter.

The Director of Cattle Breeding concluded :—"In the name of the Minister of Agriculture I thank you for your visit and wish you, also in the name of the joint representatives of the cattle breeding industry and trade, who are present here, and of the staff of the General Direction of Cattle Breeding, a happy return and a pleasant recollection of this country, where you leave enduring sympathy."

Mr. Young, in thanking the assembled company for the hospitable demonstration, said that during his visit he endeavoured to fulfil the duties entrusted to him, in an efficient yet impartial manner. He was afraid, however, he had forgotten to make a study of an "after dinner" speech. Personally, he should prefer to spend another day in a refrigerator rather than make a speech, nevertheless, it would be ungracious not to reply to the eloquent speech of Dr. Suarez. It was clear to all the parties interested that the Argentine Ministry of Agriculture had nothing to hide." This was not the time or place for referring to his report, but he could echo truthfully the words of Dr. Suarez when he said that the Ministry might await the report without anxiety. From the moment of his arrival, and during his investigation, he was strongly impressed by the frank manner in which he was allowed to see everything, not only by officials of the Ministry, but by the managers of cold stores and their assistants. Referring to the action of the London delegate of the Ministry of Agriculture, Dr. del Castillo, Mr. Young said that he had greatly helped to smooth away many difficulties. He was in their markets or at their ports, and saw what was rejected; he reported to his Ministry, and immediately correction followed. He might add that Dr. Howarth, Chief of the Public Health Department of the City of London, and Dr. Williams, Chief of the Port of London Inspection, were of the same opinion as himself, namely, that Dr. del Castillo was "the right man in the right place." (Applause.) Coming back to the question of meat inspection, he wished to say that the Ministry of Agriculture, and its inspectors had duties of great responsibility, and they were doing everything possible to convince the people of Great Britain that they intended discharging them conscientiously. The magnitude of their work was enormous, and would be appreciated when he told them that during last year Argentina exported about 70 per cent. of the whole meat imported into Great Britain. It was the earnest wish of the Corporation of the City of London and of its members to keep going the Argentine meat industry, to deal justly by the producers, and to have harmonious relations with all interested, and, as good friends, to take into account any fault when it was pointed out by either of the two parties. He had not time to visit properly their wonderful and extensive country, but through the kindness of Mr. Duggan he had visited one of the large estates, and seen their thousands of cattle grazing on thousands of acres of the most excellent pastoral land in the world. If he might offer a suggestion, he would advise every estate owner not to slaughter any cows or female calves, because, in his opinion, there would in future be a large demand for meat; prices will have a rising tendency rather than falling, at least for a certain number of years. Mr. Young, in conclusion, thanked the Government for its cordial and practical co-operation, and the cold storage firms for the way in which they had facilitated his task, and also for the hospitable and kindly demonstration offered to him—*Meat Trades' Journal*, ex *La Prensa*.

It was reported to the last meeting of the Mansfield Town Council that recently two horses had been slaughtered and sold in the town as prime English beef. The Health Committee undertook to investigate the matter.—*M.T.J.*

SPECIAL RESERVE OF OFFICERS.

ARMY VETERINARY CORPS.

The following Lieuts. (on probation) are confirmed in their rank :—

F. Roche and C. S. Stewart.

THE NEW YEAR'S HONOURS.

His Majesty has been pleased to direct that the following be sworn of His Majesty's Most Honourable Privy Council in Ireland :—

Sir CHRISTOPHER NIXON, Bt.

Sir Christopher Nixon is a distinguished Irish physician. Educated at Beaumont and Trinity College, Dublin, he is Professor of Medicine at the Catholic University. He was the first President of the Royal Veterinary College of Ireland, which he took great interest in establishing. He was created a baronet in 1906.

COLONIAL OFFICE LIST.

ORDER OF SAINT MICHAEL AND ST. GEORGE.

The King has been pleased to give directions for the following promotions in and appointments to the Most Distinguished Order of Saint Michael and Saint George :—

K.C.M.G.

* * * *

ARNOLD THEILER, Esq., C.M.G.

Director of Veterinary Research, Department of Agriculture, Union of South Africa.

ORDER OF THE INDIAN EMPIRE.

The King has been graciously pleased to make the following appointments to the Most Eminent Order of the Indian Empire :—

C.I.E.

* * * *

Maj. JOHN DALRYMPLE EDGAR HOLMES,

M.A., D.S.C., M.R.C.V.S.

Indian Civil Veterinary Department, Imperial Bacteriologist in charge of the Veterinary Laboratory at Muktesar.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1331.

JANUARY 10, 1914.

VOL. XXVI.

THE NEW YEAR'S HONOURS LIST.

All veterinary surgeons will have been gratified by last week's announcement that Dr. Arnold Theiler, C.M.G. has been advanced to K.C.M.G., and that Major J. D. E. Holmes has received the C.I.E. Both men are so widely known that we need not recount their careers. One, a Swiss graduate, and an Honorary Associate of the R.C.V.S., is the leading authority upon veterinary bacteriology and protozoology in British South Africa. The other, a M.R.C.V.S. of less than nineteen years' standing, has attained quite a similar position in India. Both have done incalculable economic service to agriculture, and this is probably the chief reason for their inclusion in the Honours List. Both have done, and are still doing, original scientific work of the highest quality, and that is perhaps our chief cause for pleasure at their selection for honour.

Viewed simply as signs of the times—as indications of the increasing recognition of veterinary work by the State—these appointments are encouraging. Royal honours have always been sparingly bestowed upon veterinary surgeons, but they have been distinctly more frequent of late years. Considering our small numbers, it seems likely that before long we shall have our full share of such distinctions. Further, such distinctions have hitherto been conferred chiefly either upon Army veterinary surgeons, or upon civilians in this country. When two are awarded simultaneously for work done in civil departments in South Africa and India, it shows that the Government has fairly recognised the value of civil veterinary work abroad.

SCHEDULED DISEASES—A SUGGESTION.

The question whether any additional diseases ought to be scheduled by the Board of Agriculture might profitably be given a full discussion by some veterinary association. Such a discussion, would be most advantageously carried on by a meeting of country practitioners; for the diseases which arise first in the mind when the question is asked are found chiefly in the country. Many men think that the time has come when John's disease and bovine contagious abortion, in particular, should be dealt with by the law. Neither is yet very common, but neither is rare; and scheduling would do something to check the sales of infected animals that frequently occur, at least in the case of contagious abortion. Veterinary surgeons collectively are the best judges of the amount and kind of damage a disease is doing, and of the possibilities of controlling it legally. They might well, therefore, discuss this question.

POTATO POISONING IN CATTLE.

By E. McSWINEY, M.R.C.V.S. Cork.

On December 5th ult., I was called to attend ten calves, two of which were said to be dying, and a third was unwell. The calves were aged from seven to nine months. All of them were fed once daily, for a week previous to the illness, on a heavy feed of small potatoes (cooked) and a little Indian meal, with hay, grass and water *ad lib*.

Everything went well until 11 a.m. on the 5th, when the owner noticed two calves standing but scarcely able to move. A small quantity of fluid faeces, black in colour, was passed; all food was refused; the abdomen was not distended. That was the information I got from the owner.

I reached the patients at 6.30 p.m. on the 5th, when I found the following:—

Calf 1 was stretched, apparently unconscious. The corneal reflex was absent; respirations very slow and nearly imperceptible; extremities warm. The calf appeared as if under the influence of a narcotic drug.

Calf 2 was lying on the chest and partly on the left side, with the head turned to the right shoulder, like a cow in milk fever. He was drowsy and semi-conscious. If the head was drawn forward it returned to its former position when released. The breathing was regular and at times snoring. The corneal reflex was not absent, though nearly so.

Treatment. Both calves received first a subcutaneous injection of strychnine ($\frac{1}{2}$ grain). About 15 minutes later each got a subcutaneous injection of 10 ounces normal saline solution (hot) in four different parts of the body. (Both calves felt the insertion of the rather large hypodermic needle). Just before giving the saline solution *Calf 1* showed twitchings over the shoulder and spasmodic movement of one fore limb—probably the result of the action of the strychnine.

The rumen of both calves was now punctured, when a small quantity of foul-smelling gas escaped as well as a dirty grey fluid. The abdomen was not over-distended, but I thought it advisable to puncture.

In about 12 minutes after using the saline solution *Calf 1* held up the head and opened the eyelids. *Calf 2* at this stage showed no improvement.

I now directed my attention to *Calf 3*. He showed no signs of illness beyond a little stiffness in walking. Temperature was normal. I prescribed a purgative.

Calves 1 and 2 were now conscious enough to

swallow. Having nothing else at hand I advised that each be given immediately, in one dose:

R. Ol. lini Oj.
Spts. frumenti 3v.

and directed that in two hours both were to receive one pint of tea infusion—the ordinary tea such as the ladies take, but the bovine dose was to be ten times as strong. The tea was to be repeated after a further lapse of two hours.

When the owner visited the calves at 4 a.m. next morning (6th ult.) he found both of them walking about the yard. Faeces were not passed even up to 10 hours; and food was not taken for four days later. All recovered in the course of a week.

Remarks. It is likely that the illness was the result of the ingestion of large quantities of potatoes, some of which were black. The symptoms presented to me were simply prostration and drowsiness. Had the patients been seen earlier probably other symptoms would be noticed. The owner's description of what he saw was given intelligently, but he had not seen the calves from the evening of the 4th until 11 a.m. on the 5th. The patients could be ill during the night of the 4th. None of the calves had received any potatoes for twenty hours previous to the time the first symptoms were noticed.

CYSTICERCUS CELLULOSÆ IN THE PIG.

According to Ostertag, it was the prevalence of this disease which led to the establishment of special sale booths, "measle banks," or freibanks. He also says, "wherever meat inspection has been introduced, *Tænia solium* of man, which develops from the hog cysticercus, has become of rare occurrence."

Neumann says, "Measles occurs frequently in Ireland, Slavonia, certain parts of North America, France and Germany. It appears in the form of an elliptical vesicle showing towards the middle of its length a white spot which corresponds to the invaginated head. The cysts are lodged in depressions excavated in the substance of the organs; they are found almost exclusively in the muscular masses. The measles is sometimes so generalized that cysticerci are met with in all the striped muscles of the body."

The carcass which I saw was that of a well nourished pig, brought over from Ireland for slaughter. Nothing had been noticed which would lead to suspicion in any way.

On slaughter, the whole of the musculature was found to be riddled with white cysts about the size of rice grains, and any movements caused numbers on the cut surface to drop out, leaving pits in the muscle.

The lungs, liver, kidneys, and fat appeared to be free, but there were a number in the substance of the heart muscle.

The tongue showed towards its base semi-transparent, globular vesicles in the sub-mucous connective tissue which could be felt with the finger, and,

if there had been any suspicion, could have been detected in the living animal.

Microscopical examination of a cyst showed the four suckers and the double crown of hooks.

Significance. *Cysticercus cellulosæ* when eaten by man develops into the *Tænia solium*, a tape-worm inhabiting the alimentary canal; but as auto-infection can take place in man and the cysts invade the vital organs, it is doubly important to prevent the sale of measly pork for food purposes.

AUTOGENOUS VACCINES.

From various reports it appears that the profession has taken to vaccine treatment, and I, as well as others, have taken advantage of all the information on the subject I could get. Mr. W. M. Scott's book was very welcome. I have also heard that others, like myself, have had indifferent results from stock vaccines—a perusal of the following will plainly show why. Personally I did not know of any firm in this country making autogenous vaccines for veterinary purposes, but when I saw Evans Sons Lescher and Webb (Superintendent of Laboratories, Dr. Annett) advertising the fact, I at once wrote in connection with two cases of mine, secondary strangles and poll evil.

I was first called in to the former on October 10th and left him on October 13th to all appearances progressing favourably. Twelve days later his condition was not satisfactory—a secondary form had set in, since when he has developed numerous abscesses of various sizes continually on his lips, cheeks, intermaxillary spaces, throat and one on his chest. What is taking place internally I do not know.

Treatment was commenced with streptocine (100 million devitalised streptococci per c.c.), 2 c.c. increasing to 6 c.c., but with no benefit; then anti-suppurine (70 million staphylococci, *albus*, *aureus*, and *citreus*; 20 million streptococci and 10 million bacillus coli per c.c.) increasing to 6 c.c. was tried but of no avail.

Then I wrote to the above firm and on Dr. Annett's instructions sent samples of pus from four different abscesses. His report was as follows:—"Cultivations made from the specimens have yielded the following organisms;—

1. *Streptococcus brevis*.
2. *Staphylococcus albus*.

From these an autogenous vaccine has been prepared of which six doses are sent herewith. Each dose (1 c.c.) contains 500 million streptococci and 2,000 million staphylococci. I would suggest that the initial dose be only half this and only if no reaction occurs will it be necessary to increase the dose to 1 c.c. Should 1 c.c. produce no reaction then 2 c.c. can be applied at the next injection. It is essential that a slight reaction should occur if the vaccine is to do any good; the reaction will consist of;—

1. A small rise in temperature (1° — $1\frac{1}{2}^{\circ}$).
2. Probably some little discomfort.
3. First, increase and then diminution in the quantity of pus."

I have now injected the patient three times and apparently there is an improvement. I anticipate, however, that prolonged treatment will be necessary on account possibly of deep seated necrosed areas and probably a fibrous formation of the non-chronic thickenings may prevent free irrigation of the tissues.

With regard to the poll evil, the report is as follows:—"Cultivations made from the pus have yielded cultures of the following organisms:—

1. *Bacillus coli*.
2. *Staphylococcus aureus*.
3. *Staphylococcus citreus*.
4. A short irregular streptococcus.
5. A diplococcus of uncertain species.

From the cultures an autogenous vaccine has been prepared of which six doses are sent herewith. Each dose = 1 c.c. contains 1,000 million each of No. 2 and No. 3 and 500 million of each of the other three. It is suggested that the initial dose should be $\frac{1}{2}$ c.c. and the dose be increased only if no reactionary improvement occurs after the injection of $\frac{1}{2}$ c.c. The interval between the doses should be 4-6 days."

I commenced this case on November 25th by chloroforming, removing considerable quantities of necrosed tissues, and giving as good drainage as possible. Three days later I began injecting anti-suppurine, increasing the dose from 2 c.c. to 6 c.c. When operating I did not find evidence of diseased bone, but the smell of late has been rather characteristic. Has No. 5 anything to do with that? In any case progress was not satisfactory, and is there any wonder? Consider the above report and the composition of anti-suppurine; consider also the doses—Mr. Scott mentions these in his book.

Autogenous vaccine	($\frac{1}{2}$ c.c.)
<i>Bacillus coli</i>	250 million
<i>Staphylococcus aureus</i>	500 "
" <i>citreus</i>	500 "
Short irregular streptococcus	250 "
Diplococcus of uncertain species	250 "
Total	1250 million
Antisuppurine (2 c.c.)	20 million
<i>Staphylococcus albus</i>	140 "
" <i>aureus</i>	
" <i>citreus</i>	
<i>Streptococci</i>	40 "
Total	200 million

Commencement with the autogenous vaccine was only to-day, so no result can be given. I am not concerned with that now. It is a question of stock *versus* autogenous vaccines; and I may here mention that the cost is not so very much more. It would appear that we are not justified in using stock vaccines, except as a first injection, until an

autogenous vaccine can be procured. The laboratory report contains the following:—"Sample received 9 a.m., 31st December, 1913. Report issued 11 a.m., 3rd January, 1914," in other words, I posted the pus on Tuesday evening, and received the vaccine on Sunday following. It behoves us to use only autogenous vaccines as far as possible. We have the advantage of the medical men, as Mr. Scott ably puts it in the preface of his book, and my friend, the village doctor, here agrees with him, he believes vaccine treatment will be submitted to cheerfully by his patients after they have been educated to their use, and not accepted only as a last desperate resort in chronic cases where all other means have failed.

I am wondering how long we veterinary surgeons are to be allowed to keep the vaccine treatment in our own hands. I have now in front of me a medicine firm's advertisement containing the following:—"Quarterines"—"vaccine so easily applied no special knowledge required." The prevention of blackleg is already passing from us, and the price is the same as I have paid for the material. Huntsmen, too, can procure distemper vaccine, hypodermic needles, and all instructions otherwise than through the profession; and then there is tuberculin.

There is a ray of hope, for in Scott's Clinical Bacteriology and Vaccine Therapy, he says that successful results can only be obtained by the strictest observation of every detail. Long may it be so, for this may prove our salvation; the word "routine" should have no place in the veterinary surgeon's vocabulary.

Also, makers of vaccines could protect themselves and us by binding over their assistant under a penalty not to do similar work for firms other than those supplying the medical and veterinary professions—a similar custom is in vogue with dentists.

Ulceby, Lincs.

ABSTRACTS FROM FOREIGN JOURNALS.

ABSCESSSES IN THE INGUINAL GLANDS AS MECHANICAL OBSTRUCTIONS.

F. Hopfe, of Löbau, records the two following cases. A horse suffered from gradually increasing constipation, which after a few days caused colic. A professional examination was then made, and showed that the rectum was completely blocked by a tense swelling on the left side of the pelvis. An abscess of the left internal inguinal lymphatic glands was suspected, and it was decided to open it from the rectum. The swelling was punctured through the rectum with Dieckerhoff's hollow trocar, and a considerable quantity of foul smelling pus flowed away. The discharge of the pus was accelerated by massage from the rectum, and the abscess collapsed. The constipation was then treated by ordinary methods, and the horse re-

covered. The opening of the abscess had no ill effects.

The second case was a pregnant cow. She became tympanitic after eating clover, and the rumen was punctured by a herdsman. The wound healed quickly. Three weeks later the cow showed symptoms resembling labour pains, and the owner expected an abortion. Rectal examination revealed a tense swelling situated upon the left side of the pelvic wall, and almost completely filling up the interior of the pelvis. It was impossible for the flat hand to get past the swelling. Abscess of the left inguinal glands was diagnosed, and the swelling was punctured through the vagina with Dieckerhoff's hollow trocar. As the pus flowed away in small quantity, the opening was enlarged with a lancet, so that it was possible to penetrate into the cavity. The pus was found to contain crumbly and shredded *débris* of tissue. The abscess was washed out and gradually emptied by means of a tube introduced into it.

The cow was delivered of a dead calf two days later, and for some time afterwards she suffered from uterine catarrh, but nevertheless recovered. In this case also, the opening of the abscess had no ill results.—*Berliner Tier. Woch.*

THE INFLUENCE OF EXTRACTS OF ORGANS UPON THE SECRETION OF MILK.

Léopoldo Giusti reports (*Revista Zootecnica de Buenos Aires*) that certain extracts of organs, when injected intravenously into the cow, directly stimulate the secretion of milk. Extracts of the pituitary body, the thymus, the parotid, the udder, the spleen, lymphatic glands, thyroid, "yellow bodies," and uterus all have this effect.

Extracts from the stomach, intestine, lung, oviduct, placenta, vagina, cerebrum, cerebellum, heart, liver, pancreas, supra-renal capsule, testicle, and kidney have no effect upon lactation.

The action of these organic extracts upon lactation is transient, and diminishes when the injections are repeated. The results are almost identical with macerated organs, or with cooked organs.

The extract of the pituitary body is the one which exercises the strongest and most manifest action. In the case of this extract, the action is not confined to the quantity of the milk, but also affects its quality by augmenting its fatty matter.—*Annales de Méd. Vét.*

BOVINE CEREBRAL TUBERCULOSIS.

Rieussec records (*Revue Vétérinaire*) the case of an ox to which he was suddenly called on account of a condition of violent excitement. The animal was absolutely furious, flinging himself on all sides in the stall, trying to climb the manger, bellowing, and striking with his horns into the empty air. These delirious attacks were succeeded by lulls and periods of dullness, during which the general sensibility disappeared, or at least was greatly attenuated. Rieussec diagnosed a cerebral congestion, and instituted appropriate treatment.

The delirious attacks then disappeared, leaving a condition of profound dullness, accompanied by a

convulsive movement of the jaws. The prehension of food was impossible, and when the attendants succeeded in placing a little food in the mouth, its deglutition was accompanied by a convulsive movement of the muscles of the neck and shoulders. At the end of five days the animal died.

Post-mortem, in addition to tuberculous lesions of the splanchnic cavities, the author found a tuberculous mass upon the right cerebral hemisphere, and some small tubercles upon the falx cerebri.

The case was, therefore, one of generalised tuberculosis with encephalic localisations. The uncertainty which exists regarding the cerebral localisation in the ox prevented a precise diagnosis of the region concerned being made during the life of the animal. But the case justifies the conclusion that tuberculosis should always be suspected in cases of cerebral disturbances, whatever their course may be.—(*Annales de Méd. Vét.*)

W. R. C.

SOUTHERN COUNTIES VETERINARY SOCIETY.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The customary December meeting was held at the Holborn Restaurant, London, on the Wednesday during the Cattle Show week, and was followed by the annual dinner. The ordinary meeting of the Society was preceded by a meeting of Veterinary Inspectors, in connection with the formation of the proposed new Veterinary Inspectors' section of the Society. The President, Mr. G. H. Livesey, of Hove, presided, and the others who signed the attendance book included Messrs. W. Caudwell, Chertsey; James Crowhurst, President of the South-Eastern V.M.A.; J. B. Dier, East Grinstead; T. A. Huband, Sevenoaks; E. W. Morris, Uckfield; P. J. Simpson, Maidenhead; F. G. Samson, Mitcham; J. Alex. Todd, West Kirby; Theo. C. Toope, Dover; and the Hon. Sec., Mr. A. H. Archer, Southsea.

The PRESIDENT explained that at the last meeting of the Society at Brighton it was decided to form a Veterinary Inspectors' section of the Society on the lines of that associated with the South Eastern V.A., and that it now rested with those of them who were veterinary inspectors to nominate a committee and hon. secretary. He took it that this new section of the Society was being formed for the advancement of the special interests of the veterinary inspectors in the counties or area covered by the Society, but, of course, the Society in taking this step were also hoping to do itself a little bit of good, and he had no doubt that the veterinary inspectors who would attend the meetings of this Veterinary Inspectors' section would before long become members of the Society, if they were not already members, and so strengthen the hands of the Society, and indirectly the hands of the National Veterinary Association, and the profession generally throughout the country. He left the matter in their hands to discuss, and if thought advisable, to nominate their committee and officials.

Mr. CROWHURST asked whether any veterinary inspector had a *locus standi* at that meeting, adding that he himself was an inspector, but that he had been invited there as a visitor.

The PRESIDENT replied that they were pleased to welcome any veterinary inspector. Their object was to form an Inspectors' Branch of their Society, and the views, help, and assistance generally of any veterinary inspector acting in any part of the country were wel-

come, and if they could assist them in forwarding the objects of the meeting they were more than welcome.

Mr. MORRIS thought they were too small in numbers that afternoon, and that the matter had better be adjourned till they had a larger attendance.

Mr. DIER: There were really very few of them there that day, and he believed three of them were already on the committee of the South Eastern V.A. He was afraid whether they were not going to split themselves up into too many sections, and he thought that if the two Societies could combine and form one representative committee they were likely to have much more effect in any action they might decide to take.

Mr. TOOPE remarked that that was practically the suggestion he was going to put forward later on—that they should have a committee for the southern division, but there was no objection surely to their making a start that day. They would be having another meeting on the 15th January at Tunbridge Wells, and they could continue the discussion there if they liked.

Mr. P. J. SIMPSON agreed with Mr. Dier that they could go too far in the way of splitting themselves up into too many small bodies, and that if they could get one big meeting of a more representative character they would be able to push things in a much stronger way. It seemed to him that if they were going to form separate branches of the National Veterinary Inspectors' Association they ought to take in a considerably larger area. They would then find possibly that they would be able to get a fair sized meeting. He did not wish for one moment to throw any cold water on the scheme, but unless they were going to get a better attendance than they had that day, he was afraid they would not be able to push things very forcibly.

Mr. TOOPE explained that the suggestion which he put forward at Brighton was that each Society should form a veterinary inspectors' branch or section who would meet in connection with the ordinary meetings of the Societies, and by that means they would be able to get in touch with the National Association. It was impossible for a large body representing a wide area to satisfactorily deal with the special needs of a particular district, but if they had an Inspectors' Branch of the various Societies they would be able to get the views of the local men. He suggested that they should appoint two gentlemen from each administrative county in the Society's area as a committee, and those gentlemen would then be able to voice the views and opinions of the inspectors in each district. He could only add that they would be glad to see any inspector in the Southern Counties present at their meeting at Tunbridge Wells on the 15th January.

Mr. CAUDWELL took it that all veterinary inspectors in their district had been invited to that meeting, and if the attendance that afternoon represented the interest which they took in the matter, he failed to see much hope of forming a really serviceable branch. On the other hand, if they took in a larger area than that covered by the Society, there was a danger of their making it too unwieldy. He proposed that the appointment of a Veterinary Inspectors' Committee be deferred till their next meeting.

Mr. MORRIS: The idea, as Mr. Toope had said, was to get small meetings of inspectors before the ordinary meetings of the Society, at which the inspectors could discuss matters affecting themselves. The South Eastern V.A. had a very good branch, and he did not see why the Southern Counties should not have one as well.

Mr. CROWHURST remarked that the subject was one of very great importance to the veterinary profession throughout the country, and he thought it would be acknowledged that where they had taken concerted action they had derived considerable benefit. He saw no objection to their adjourning this discussion to the

next meeting, but now they had started let them keep the ball rolling.

The PRESIDENT said that it seemed to him it would be a very great pity to shelve this matter, and it ought to be distinctly understood that if it was deferred it was only deferred, and that interest in it was not dropped. He agreed that it was far better to have a strong committee, voicing the opinions of a large district, rather than merely those of two or three, but he gathered that Mr. Toope's suggestion was practically decentralisation, the getting the opinions of small committees scattered over a large district in order to strengthen the hands of the larger committees, and in that case it seemed a pity that a Society like theirs should forego the opportunity of forming its own committee. It would be a thousand pities if this scheme was allowed to drop, and it was almost a pity to defer it for even three months. Surely no harm could be done by appointing two or three delegates from that meeting who would make a point of attending the meeting of the South Eastern committee at Tunbridge Wells with a view to crystallising the idea into something definite. Otherwise, if nothing was done that afternoon it might go forth to the profession that there was a lack of sympathy with the object, and no one would make it his business to attend at the next meeting.

Mr. MORRIS said he would gladly withdraw his proposition in favour of this course being adopted.

The PRESIDENT: That is my own idea, but of course I am not a veterinary inspector.

Mr. CAUDWELL, as seconder of the proposition to adjourn the matter, also agreed to withdraw.

Mr. DIER: I may say that we are not at all satisfied with the fees we get in East Sussex.

The PRESIDENT: Personally, I don't see why you veterinary inspectors should not form committees and hold your meetings in connection with both Societies.

Mr. TOOPE: That was my suggestion.

Mr. SIMPSON proposed that Mr. Caudwell and Mr. Dier be asked to represent that Society at the meeting at Tunbridge Wells, and that their hon. sec. write to all their other members who were inspectors telling them of that meeting, and stating that they also would be welcome.

Mr. MORRIS seconded this, and it was agreed to *nem. con.*

The PRESIDENT added that it was very gratifying to think their meeting had resulted in something being done, and that if they wanted another meeting of inspectors later in the year he was quite sure the Southern Counties Society would be only too pleased to welcome them at their annual meeting next March and return the compliment.

On the proposition of Mr. CAUDWELL, seconded by Mr. SAMSON, the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

THE LATE WILLIAM HUNTING.

The PRESIDENT remarked that before the business of the meeting was further proceeded with there was one very sad matter which he had to bring to their notice and that was the loss which their Society and the profession generally, and he might almost say the nation had sustained by the death of the late Mr. William Hunting. He was a comparatively young man himself and had only known Mr. Hunting for some sixteen or seventeen years, and as there were other members of the Society present that afternoon who had known him for a much longer period he would leave it to one of them to propose the vote of condolence which he was sure it would be the wish of them all that they should pass at that their first meeting since their friend's death. Perhaps Mr. Samson would do it.

Mr. SAMSON said he was sorry indeed that their President should have had occasion to call upon him to propose such a resolution with reference to his old friend Mr. Hunting. He had known him for about forty-five years, and had never had anything to say against him, and he had yet to meet the man who could say anything against him. He was the most pleasant and courteous gentleman one could ever wish to meet either in business or pleasure, and they would have to go a long way to find his equal. He did not know that he could say more except that his wife and himself paid a visit to the daughter last week, and that they would be pleased to know that she was tolerably well, and also Mr. Hunting's son. It was with very deep regret that he proposed they send a resolution of condolence and sympathy with the relatives in their sad bereavement.

Mr. ARCHER seconded, observing that it was a sad duty to him to have to do it. He had known the late Mr. Hunting for a good many years, and he could quite endorse every word Mr. Samson had said.

Mr. TODD also desired to associate himself with the remarks that had fallen from the previous speakers. He had known Mr. Hunting for several years, and especially during the two years he had held the presidency of that Society, when their relations were always of the very best. He remembered visiting him on one occasion when he was too unwell to attend one of their meetings at which he had promised to give them a presidential address, but they had the address all the same. He finished it on a sick bed. He felt then somehow that they were not likely to see Mr. Hunting at any more of their meetings, but fortunately he rallied and took the chair on several occasions after that. He was a man of the most marked individuality and striking personality, and certain was it that the whole profession would miss him.

Mr. T. A. HUBAND added that he should also like the privilege of being allowed to associate himself with this vote. He had had the pleasure of the acquaintance of Mr. Hunting for a quarter of a century or more, and during the whole of that time their associations had always been of the pleasantest; and it was a great grief to him, as he was sure it was to them all, when they heard the news of his death. When he saw him in the summer at Maidstone he little thought their friend was so soon to be taken away from them. He had never heard anything but the most favourable and kind opinions expressed as to his character, and he thought no one could deny that the profession had lost in him a man of unique experience and ability. He had often regretted that better notice had never been accorded the great work he did in connection with Glanders. If any man had deserved State recognition with regard to the stamping-out of malignant diseases in this country it had been their late friend.

Mr. TOOPE wished to add just one or two words. He had been brought into intimate association with Mr. Hunting in connection with "The National" during the last two years, and personally he felt his loss was almost irreparable. They would shortly have to find a new head, but the question he asked himself was where were they going to find such a head as he had been. There were few men who took a broader view of things, and few who were able to guide and lead discussions in the way he did.

The PRESIDENT remarked that before putting the proposition to the vote he should like to add his tribute to his friend Mr. Hunting. During the time he had known him he had always found him a sincere and very dear friend. He was a man of extremely broad-minded views; he was above the ordinary pettiness; his interests were always those of his profession; and there were few men of his age and of his experience who would discuss matters on which he was an expert with younger

and more inexperienced men. It was a real pleasure for instance, to see him discussing a question like glanders with perhaps a newly fledged student, never contradicting, never being at all brusque, or insinuating that he had a greater knowledge, but always listening with interest and encouraging one to go on. He thought this was a very great trait in their late friend's nature, and it had been a very great thing for their profession, because it showed the younger men that those of more mature years who had risen to the head of the profession were not above listening to their views, however inexperienced they might seem to be. In this way he had laid the foundation of a life long friendship with many a member of the profession. He was one of the very few men who were welcome wherever he went. No one ever had a bad word to say against him; everyone was always pleased to see him and have a chat with him and put their little troubles before him in the hope that he with his wider experience might be able to give them a little help. He himself had always looked upon him as a very great and personal friend. He always had the same genial manner, and was always ready to talk about dog practice, and although he personally was not interested in that class of practice it was astonishing what a grasp he had of it. He felt, as Mr. Toope had said, that they had lost a leader, and one whose place it would be extremely difficult to fill.

The resolution was then put to the meeting and carried, the members signifying their assent by rising silently from their seats.

The HON. SEC. (Mr. Archer) mentioned that when he received a card from Miss Hunting that her father had passed away he immediately 'phoned to the President, and with his approval ordered a wreath to be sent, and the Society was also represented at the funeral by Mr. Sloccock, one of their vice-presidents. He also took it upon himself to write a letter to Miss Hunting on behalf of the Society, and he had since received an acknowledgment of that communication, but he would, of course, write again after that meeting and tell them of the resolution which the members had passed that day.

Correspondence. Mr. ARCHER announced that he had received letters from Mr. Harding, of Salisbury, and Mr. Crowhurst, of Canterbury, acknowledging the resolutions of sympathy which the Society passed with them at the last meeting.

Apologies or expressions of regret at inability to attend were announced from Prof. Hobday, Messrs. W. Burt, E. Whitley Baker, V. Blake (Ryde), W. Coveney, Percival Carter (Worthing), J. H. Carter (Burnley), C. H. Gollidge, T. A. B. Cocksedge, W. A. Collins, C. F. Hulford, J. C. Munby, J. W. Pritchard, (Brighton), C. Roberts (Tunbridge Wells), H. Smith (Worthing), S. Smith (Horsham), C. H. Spurgeon, S. H. Sloccock, who hoped, however, to be able to attend the dinner, R. A. Thrall, F. Thornton, H. Taylor, J. E. Wallis (Hailsham), and A. C. Wild.

A circular communication with reference to the Sanitary Institute Congress at Blackpool next year was submitted by the Hon. Sec., but on the proposition of Mr. Todd, seconded by Mr. Dier, the question of subscribing or appointing delegates was deferred to the next meeting.

Mr. PERCIVAL CARTER, of Worthing; Mr. E. W. MORRIS, of Uckfield; and Mr. S. SMITH, of Horsham, who had been duly proposed and seconded at the previous meeting, were formally elected members.

It was also decided, on the proposition of Mr. Caudwell, seconded by Mr. Todd, that the next meeting of the Society should be held in London on the usual date.

The HON. SEC. mentioned that he had received a letter respecting the International Veterinary Congress, an extract from which, inviting donations, he had sent out with the notices for that meeting.

Mr. SAMSON: How much have we subscribed as a Society.

The HON. SEC.: I believe it was £10 10s., with a probable further contribution of a similar amount later on.

Mr. SAMSON: Then I will propose that we send another subscription of £10 10s. for the second year.

The PRESIDENT: Don't you think it will be better to defer that to the annual meeting, when we shall have the accounts before us, especially as our Hon. Treasurer is not able to be with us to-day. [Agreed.]

ANTHRAX IN THE HORSE.

By A. H. ARCHER, M.R.C.V.S.

The disease known as anthrax has so frequently been the subject dealt with in papers, letters, and articles appearing in our professional journals, etc., that some among you may consider that everything relating to this disease has been said or written, leaving nothing of interest for further consideration or debate; I, however, am not of this opinion, especially in respect of the manner in which it affects the horse, and the influence that this animal's tissues have on the bacillus, which is the recognised cause of this disease.

The remarks I am about to make are the outcome of prolonged clinical observation and study, rather than assertions or suggestions derived from theoretically scientific investigations, consequently I wish it to be understood that they are made with the desire of evoking discussion, so that doubts may be cleared up, and errors corrected in my own mind, and in the minds of others, should any be in the same plight as myself.

We all admit that the horse is affected with true anthrax, and, I believe, also agree that the form known as "gloss anthrax," where some part of the mouth or tongue is the initial centre of infection, is of this character, but it is in the so-called enteric form, or at least in some of those fatal intestinal affections which are now generally regarded as anthrax, when there is a copious pale yellow semi-gelatinous exudate into the coats of the bowels, accompanied by an intensely congested or apoplectic condition of the adjacent tissues, and of which I once heard our late esteemed and lamented president, Mr. Hunting, remark "I used to wonder what was the real character of the affection in which we find these conditions; now I know what it is. It is anthrax," or words to this effect, that further investigation is required before accepting them unreservedly as cases of anthrax.

Now I trust you will not deem me unduly, or unwarrantably sceptical, when I say unless it be acknowledged that the anthrax bacillus loses a considerable amount of its virulence in the system of a horse, then I have doubt as to the fatal disease presenting the appearances already described, being true anthrax, at any rate in many of the cases regarded as such.

The reason why I am thus doubtful is because, during a period of 35 years practice I, like others, have met with a very considerable number of these cases long before they were suspected as being of a contagious nature, and when no precautions were taken to prevent other animals coming in contact with the carcase or blood of the affected animal, yet in no single instance that I can remember was the death of a horse in which the carcase presented the appearances which are now supposed to be sure indications of anthrax, followed by an outbreak of this disease, on or near such premises, and I consider this strongly supports the contention that either this affection is not really anthrax, or if it be then the disease loses much of its virulence while attacking the tissues of the horse.

There are, I think, some differences in the symptoms exhibited during life by a horse suffering from true

anthrax, and one affected with this enteric disease regarded as anthrax. In the latter there is severe and persistent pain, obstinate inaction of the bowels after the initial stage of the attack, an accelerated full pulse, which becomes weak and thready in the later stages, but there is no special irregularity, the usual indications of suffering are present, and the countenance wears a haggard expression as the fatal termination draws near.

In anthrax there is evidence of pain accompanied by extreme dejection and a peculiar fluttering pulse in quite the early stages of an attack, and while faeces and urine are passed in an almost normal manner, these being the special symptoms which differentiate it from other abdominal affections.

In anthrax the temperature is raised in the early part of an attack, but sinks to about normal, and is often subnormal some hours before death.

This matter assumes added importance now that some insurance companies insure against anthrax.

DISCUSSION.

The PRESIDENT: Is it your contention, Mr. Archer, that anthrax as seen in the horse is not true anthrax?

Mr. ARCHER: I admit that horses do suffer from anthrax, but some at least of these abdominal cases are more in the nature of intestinal apoplexy.

Mr. CAUDWELL thought the reader of the paper would admit that science had made considerable progress since the late Prof. Robertson's time, and that he would also agree that many cases of anthrax proved fatal without the blood showing the specific bacilli. He believed it was now well understood that they could not always rely on a microscopical examination of the blood in the case of the horse.

Mr. DIER had not had a great deal of experience of anthrax in horses, but there was one thing about anthrax which the writer of the paper had not mentioned. He had always noticed that the animals showed great distress in breathing before they died, and that as a rule there was extremely little blood come from the nostrils. He had generally found that they were more likely to get the anthrax bacilli from the lymph stream than from the blood.

Mr. SAMSON confessed that he had not had a great deal of experience of anthrax in horses, but from what one had heard from other veterinary surgeons who had, one was bound to believe that there were cases of anthrax which put on the form of common colic and which were treated as such. He was speaking to a brother practitioner at Croydon market only the previous week, and he told him that recently he had been called in to two cases of what was believed to be colic but which on making a post-mortem he found to be anthrax. If this was so he was inclined to think that anthrax in the horse put on a very different form and showed very different symptoms to what it did in other animals. In anthrax in bovines they had no premonitory symptoms at all, and that opened one's eye and the post-mortem examination was made. It was a question to him whether they had two diseases combined, or whether they had a modified anthrax in the horse not similar to what they had in pigs and bovines. He could hardly conceive that true anthrax could put on these colicky symptoms and go on for forty-eight hours before the patient died. At all events it seemed to him that it wanted more investigation than they had given to it.

Mr. CROWHURST gave several interesting reminiscences of cases that had come under his own notice. One case he said was a very remarkable one. A client sent a horse into the knacker's yard with a request that he would make a post-mortem, but without giving him any history of the case. He went and made the post-mortem and found nothing whatever until he came to one of the parotid glands; that was black, and knowing that anthrax was prevalent in the neighbour-

hood from which the horse had been sent he suspected that disease, and asked for a history of the case. The owner then asked him to look at five other horses which he said would not pull or walk. One of these had a large swelling at the bottom of the neck and they were all very dull and lifeless. He told the man he had every reason to believe that he had got anthrax in his stables, and asked him if he had lost any animals suddenly, but was told no. He treated these five horses, giving them carbolic acid a drachm a day for about ten days, and every horse recovered. The following Sunday, however, a notice came that a bullock had been found dead in a field. He quite agreed that one did not get the usual symptoms of anthrax in a horse that they got in the bullock. He had had many cases of anthrax to deal with in his time, and he could put his hands on farms where they had lost more than the rent of the whole farm in stock every year for years in succession.

The PRESIDENT: What has happened to those farms?

Mr. CROWHURST: They are still let, but they are much more careful now, and we do not get so many cases.

The PRESIDENT: After your long experience in that district, Mr. Crowhurst, have you found that things have really improved as the result of proper inspection.

Mr. CROWHURST: Yes, with the exception perhaps of swine fever.

The PRESIDENT: There are fewer cases of anthrax.

Mr. CROWHURST: Yes, not so many.

The PRESIDENT: But it still exists.

Mr. CROWHURST: Yes.

The PRESIDENT: And may break out again.

Mr. CROWHURST: Yes, in spite of all the regulations you make.

Mr. TOOPE quite agreed that the symptoms of anthrax in the horse were not what they were in cattle, or even in pigs in all cases, but this was not so with regard to every case. In some they would get as marked symptoms and as quick a death as they would ever get in oxen. One thing he would like to draw attention to was the statement by Mr. Archer that many of these cases were possibly apoplexy of the bowel. He had seen many of these cases of apoplexy of the bowel and it was not everyone perhaps who would like to admit a grave mistake, especially when that mistake meant a considerable loss to one's client, but he could give them one instance in which he evidently made a mistake. He was called in to see a horse belonging to a contractor which was in a stable with ten others. The horse was in a dying condition when he saw it, but he made inquiries and came to the conclusion that it was dying from apoplexy of the bowel, and he attributed the cause to some new oats that had not been in the best of condition. Two days later he was called in to see another of the horses. This one had a swelling in the throat, and on taking the temperature he came to the conclusion that he had made a huge mistake with regard to the first one he had examined. The result was the owner lost six horses within a week. Everyone of them was dead within six hours, everyone showed symptoms of apoplexy of the bowel and five out of six showed the bacilli very plainly on making a microscopical examination. In another case he had two horses that lived three days, but in that case he discovered the bacilli during the life of the animals. The symptoms shown in this case also were not bowel trouble but acute congestion of the lungs. He thought the symptoms largely depended upon the place of original invasion. He believed also there was now a process of finding out whether anthrax existed by staining, and that M'Fadyean held that it was possibly diagnostic.

Mr. MORRIS remarked that there was one point he would like to mention. He had sent up a considerable

number of anthrax specimens to the Board, and he had sent them stained in two methods whereas they had asked another man whom he knew, not to send them stained.

Mr. CAUDWELL said that his instructions had been not to send stained specimens. Staining was most distinctive, however, and they ought to make no mistake, especially when they got fresh blood. With regard to the susceptibility of the animals, it was not necessarily a fatal disease. Then, again, some species apparently had more resisting powers than others, and altogether it was a very curious disease.

Mr. HUBAND asked Mr. Archer if he would tell him in what condition he found the spleen in those cases of abdominal apoplexy which he had mentioned. Personally, he did not recollect ever seeing a true case of anthrax in the horse, but in his early days he met with many cases which would readily answer to the description he had heard from Mr. Archer and Mr. Toope. There was also one other very peculiar feature which he had noticed. Supposing an affected carcase, say of a sheep, was hung up in a building that was infested with rats. In the ordinary case the rats would tear that carcase to pieces in a single night, but if the carcase was an affected one they left it severely alone.

Mr. TOOPE replied to Mr. Huband's question that he had not found the spleen to be particularly affected in the horse. Sometimes they would get it considerably engorged, but not by any means in every case.

Mr. ARCHER: In the cases of abdominal apoplexy, as Prof. Robertson used to call it, they got acute congestion rather than inflammation of the bowels. His own clinical experience made him doubt whether there was not a condition of the bowels which simulated anthrax, which was not true anthrax but intense congestion. It was also very easy to mistake anthrax for malignant oedema.

Mr. MORRIS remarked that the bacillus of the latter was gram negative, whereas the anthrax bacillus was gram positive.

Mr. TOOPE: Yes, and further, I believe malignant oedema is also associated with a certain amount of air in the tissues.

Mr. ARCHER, continuing, thought there was no doubt that anthrax did assume different forms according to the mode of entry. Where they got the affected portion near the mouth or throat there they would get throat symptoms, but where the point of infection was the bowel they would get bowel trouble. In all those cases where they got the chief lesions in the bowel they would always get these colicky pains, but they were quite different from ordinary enteritis. At all events he thought these abdominal cases deserved a little more attention than they often received.

On the proposition of Mr. Caudwell, seconded by Mr. Samson, a hearty vote of thanks was accorded Mr. Archer for his paper, and after Mr. Caudwell, the President, and Mr. Toope had mentioned three cases of interest, the proceedings closed with the usual compliment to the President for presiding, proposed by Mr. Samson, and seconded by Mr. Caudwell.

ANNUAL DINNER.

Mr. F. G. SAMSON, of Mitcham, presided at the dinner, and he was immediately supported by the chief guests of the evening, Mr. G. H. Livesey, the President; Mr. J. Alex. Todd, the late Hon. Sec.; and Mr. Crowhurst, the President of the South Eastern Veterinary Association, as his immediate supporters, and in addition to most of those who had been present at the meeting earlier in the day, the company also included Mr. Todd, sen., (Brighton), Mr. W. H. Brown (London), Mr. S. H. Slocock (Hounslow), Mr. E. R. Douglas, and Mr. H. S. Mitchell (Worthing).

At the conclusion of the repast the customary loyal

toast of the King was submitted from the chair and duly honoured, and this was followed by that of

"Our Guests and Visitors," which was proposed by Mr. S. H. Slocock. It was the privilege of all the veterinary societies that he was acquainted with to invite guests to their social gatherings, and this had been a particularly prominent feature with their own Society. On that occasion they had several guests with them who were honoured members of their own profession, and who had done much for their Society in the past. Their President, Mr. Livesey, had been one of the most active members not only of their own Society, but also of the other Societies to which he belonged, and the fact that he specialised to a great extent always made him particularly worth listening to. Then they also had with them as their guest that evening Mr. Todd. He believed he ought to call him Captain Todd, but to them who knew him he was usually called Todd. (Laughter.) As their late hon. secretary for several years Mr. Todd had done a marvellous work for them, and it must have been a great satisfaction to him to see the Society make the progress which it had. They were also pleased to welcome as their guests that evening Mr. Crowhurst, the President of the neighbouring Society, and Mr. Brown, both of whose names he also desired to couple with the toast. (Applause.)

The toast was cordially received, and

Mr. LIVESEY, in returning thanks, remarked that his year of office had been a very pleasant one. At the same time there were one or two regrets which he could not refrain from mentioning. One was that the meetings had not been better attended, a second was the loss the Society had sustained by Mr. Todd transferring his energies to the North of England, while another regret was the great loss the Society had sustained by the death of his predecessor in the chair, their old friend Mr. W. Hunting. Mr. Hunting had been a difficult man to follow, but he must say that since he had been in the chair their reception of himself had been most kind. They had been tolerant of his rulings, and generally had given him every assistance. Mr. Todd had been succeeded in the hon. secretaryship by Mr. Archer, and he hoped that under him the Society would take on a fresh lease of life, that new and active members would join their ranks, and that their meetings would be better attended. It did seem a pity that a Society which was doing such a good work as theirs was, and which discussed matters of vital interest to the profession, should meet with such apathy on the part of the great body of veterinary practitioners, and he hoped that they would use their influence with all the professional colleagues whom they were acquainted with, not only to become members if they were not already members, but also to make a greater effort to attend the meetings of the Society in the future. (Applause.)

Mr. J. ALEX. TODD, in the course of his reply, remarked that he hardly knew how to thank them and absent members adequately for the very great kindness they had shown him and the honour they had done him, not only that evening but also last September. He was very sorry to have to send in his resignation, but it was impossible for him to continue the office when he was so many miles away from the district. They had very kindly subscribed a testimonial to him, and he had duly received from Mr. Whitley Baker a handsome cheque—one quite out of proportion if he might say so, to anything he had done for them. ("No, no.") There had been a good deal of discussion in his family circle as to the form that present should take, but he thought it had now come to a head, and acting on the very practical suggestion of his wife, and on her behalf he also wished to thank them, they were going to invest in a canteen of cutlery. He could assure them it had been a very great pleasure to do anything in the secretarial way for the Society during his period of office, and he

esteemed it an honour to have been associated with the eight gentlemen who had held the office of President during the nine and a half years he had been their secretary. There was one sad thought about this, however, and that was that four of those eight gentlemen had passed away. There was first their old friend Mr. Fred Spencer, whom he might describe as a typical country practitioner; then they lost Mr. Frank Wragg, whom he might describe as a typical London practitioner; they had also lost Mr. Richard Roberts, who was one of the best; and lastly, they had lost their dear old friend Mr. Hunting. He had nothing but the most pleasant recollections of his associations with all, especially Mr. Hunting, and he always regarded it as a great misfortune that when they held their meeting at Salisbury during the second year of Mr. Hunting's presidency they did not have a larger attendance to listen to his extremely interesting paper on his reminiscences of fifty years of veterinary practice.

He hoped that would not be the last occasion by many that he would meet them there, and he again thanked them sincerely for the great honour they had conferred upon him, and for the practical kindness they had shown him. (Applause.)

Mr. W. H. BROWN, in the course of his response, remarked that he had once again to thank them for their hospitality, which had become almost a tradition in the South of England. He was very pleased to be with them again. They all knew his connection with the profession, which began in 1888. There had been a material change in it since he last met them, for his much respected chief had passed away. Although there had never been anything more between them than a mere verbal agreement, they had worked together for five-and-twenty years, and he need hardly tell them they had worked together most amicably, and he might also add, successfully. There was just one or two words more he would like to say of a personal character. The conduct of *The Record* had now fallen into his hands, mainly through Mr. Hunting's instrumentality, and with it had passed the responsibility, but he could promise that as long as he had anything to do with it, the paper would continue to be run in the interests of, and for the benefit of the profession. (Applause.)

Mr. CROWHURST also made a brief but appropriate response, and then proceeded to propose the toast of "Continued Success to the Southern Counties Veterinary Society." He believed it was one of the oldest of the veterinary societies, and it was one that had done a great deal of good work for the profession, and one which he hoped would continue to do good work. On looking down the list of their past Presidents, he saw they had had many illustrious members of their profession in their ranks, and he was sure they all wished the Society every success in the future. He coupled with the toast the name of Mr. Morris, of Uckfield. (Applause.)

Mr. MORRIS, in reply, remarked that he would have much preferred the task had fallen into other hands, as he had only been a member of the Society for a few hours, but he heartily thanked Mr. Crowhurst for his kind wishes, and them for the cordial manner in which they had endorsed his remarks. He hoped that next time they met they would have a larger attendance, and also that someone more worthy would be found to respond for this toast.

The next toast on the list was that of "The Chairman," but before this was proceeded with,

Mr. LIVESEY said that he had a very pleasing duty to discharge in his capacity as President of the Society, and that was to hand a little souvenir of their regard to Mr. Todd. (Applause.) They would remember that last September they made a little presentation to Mr. Todd as a small recognition of the great services he had

rendered the Society during the time he had held the office of hon. secretary, and to remind him of their good feelings towards him when he was absent from them. As Mr. Todd was then on the move, and they had no opportunity of consulting his wishes, it was decided to hand the money subscribed over to him in the form of a cheque for him to spend it as he pleased, but that gift was also to be accompanied with an illuminated address which he could hang on the walls of his house as a mark to all those who entered it of the esteem in which he was held by his brother practitioners in the Southern Counties, and it was with the very greatest pleasure that he now asked Mr. Todd to accept this address. (Applause.)

The address which bore the names of the subscribers to the testimonial and was beautifully illuminated and framed, read as follows:—

"We, the undersigned members of the Southern Counties Veterinary Society, beg your acceptance of the accompanying token of our appreciation of the valuable services you have rendered to the Society for the last nine years, and which have mainly contributed to its growth and prosperity, and to assure you how deeply we regret your departure from the district where your abilities have been so highly valued. We wish you in all sincerity every success in your new sphere of labour, with good health and happiness to attend upon your future career."

Mr. TODD, who had another cordial ovation on rising to accept the address, made a brief acknowledgement, observing that it would always be greatly cherished by himself and his family.

The PRESIDENT gave the toast of the Chairman, and Mr. Samson in reply, recalled some interesting reminiscences of the earlier days of the Society when the members used to meet at the old "Greyhound," at Croydon.

Mr. THEO. C. TOORE proposed the health of the Hon. Treasurer and Hon. Secretary, which was also received with enthusiasm.

Mr. ARCHER, in reply, remarked that he fully realised he had a difficult task to follow such a capable secretary as their friend, Mr. Todd, he could only promise to do his best, and he hoped he should be supported by the members, and that they would be able to revive interest in their proceedings and get their meetings better attended.

TUBERCULOSIS IN CATTLE.

Quite recently I read the report of a very interesting and instructive address by Sir John M'Fadyean.

Referring to tuberculosis in cattle, Sir John says:—"As an excuse for the inaction of owners in the direction of eradication, it has been said that many farmers in this country are still ignorant of the fact that tuberculosis is a purely contagious disease, and believe it to be generally inherited from one or other diseased parent."

We must all agree with Sir John that "tuberculosis is a purely contagious disease," and we may add that every infectious or contagious disease is due to the presence in or on the body of some living organism.

The farmers in Ireland, thanks to Lady Aberdeen, are well aware that the disease is infectious, but they also know, by careful observation and experience, that the disease, in the lower animals and in man, is in some way or other hereditary, and if we expect our opinions to be accepted unreservedly, I think we ought to be very explicit and make it perfectly clear that there are other contributory causes of the disease besides the specific microbe, and one of these causes is almost as important

as the microbe itself. Unfortunately the one essential cause, the infection or contagion, cannot be avoided, but it can be greatly diminished in quantity and potency. The next factor in importance is an inborn predisposition to the disease, but, fortunately, this cause is hereditary and can be easily removed without any cost to the nation; and but for erroneous theories relating to heredity which have been industriously promulgated for the last fifteen or twenty years, tuberculosis in our herds would now practically be a thing of the past and another great achievement placed to the credit of the veterinary profession. Needless to say, the innate power to resist the disease, under ordinary circumstances, may be much increased or diminished.

There are no two opinions as to the importance of good ventilation. Obviously there are two opposing factors bearing on the incidence of the disease—the virus to which the animal is exposed and the power possessed by the animal to resist the disease. Ventilation operates in a dual capacity, diluting the virus and strengthening the innate or inherited powers to resist the disease. There is some difference of opinion as to the best and simplest methods of ventilation with the view of increasing the disease-resisting forces and also with a view to economy. There are other factors which need not be considered at present, such as sanitation, the beneficial and the harmful effects of sunshine, etc., etc.

There is one subject which does not appear to have received due consideration, that is how to obtain the milk best suited to the needs of the infant and which is the most easily assimilated.

The practice of dairymen in many large cities is to keep purchasing half-bred "springers" all the year round, and as far as practical "fattening off," all the time. These men never keep the cows more than one season, and it is surprising the very large percentage of these cows which passes the most rigid inspection at the abattoirs. Some people denounce this practice. They would have all reactors sent to the knacker. They do not consider who is to pay for this wanton waste. Everyone must admit that the sooner reactors leave the dairy the sounder the meat, not to speak of the enormous advantages of a pure milk supply. Some people are sticklers for the purely contagious theory, but they make no protest against the practice of allowing cattle to cough over one another's food, etc., and seem to ignore heredity as a factor entirely. Some enterprising dairy keepers remove all reactors from their stock, but these reactors invariably find their way to other dairies to further contaminate same.

Some people hold extraordinary opinions regarding heredity. They seem to think that no disease can be hereditary unless it is congenital. Some of these people are bacteriologists, clever no doubt in their own way, but, without extended experience and careful observation, their knowledge of bacteria does not help them in the least. They seem to ignore the fact that predisposition to certain diseases are often inherited from grandparents whom they never saw. With regard to the lower animals, proneness to disease is often inherited from the sire with whom they were never brought into contact.

We must believe, what every bacteriologist tells us, that calves are rarely born with the disease: in other words, the disease, though hereditary, is practically not congenital. Farmers and stockbreeders are rather practical in their ideas, and they do not seem to mind whether the causal bacilli enter the body before or after birth. They know that the offspring of affected animals are peculiarly prone to the affection. I think we ought to make it quite plain to the stockbreeder that it is the inborn predisposition to the disease which is inherited, and not the microbe. This is the

opinion now held by the great majority of veterinary surgeons practising in Ireland, and their opinion is supported by the unanimous verdict of leading medical authorities.

Perhaps I may be excused for quoting a few of these opinions.

Munro, in his *Manual of Medicines*, University Series, says:—"Of late years it has been fashionable to minimise the importance of inherited predisposition. . . . The seed is essential, but the soil is scarcely less important."

T. J. Horder, F.R.C.P., Physician to the Great Northern Central Hospital, Chelsea, says:—"The existence of tuberculous families is one of the cardinal facts of clinical medicine. There is a tissue susceptibility, a 'favourable soil,' that constitutes a potent element in the pathology of the disease."

J. Walter Carr, F.R.C.P., Physician to the Royal Free Hospital, says:—"The discovery of the part played in the production of tuberculosis by the tubercle bacillus has led us, perhaps, to attach too little importance to the influence of heredity. . . . What undoubtedly is inherited—and to this, perhaps, at the present day too little importance is attached—is a diminished resistive power to infection by the tubercle bacillus. Unquestionably, from time to time nearly everyone is exposed to infection by tubercle bacilli, but, fortunately, in the great majority of instances the bacilli succumb to the defensive forces of the body."

Sir Richard Douglas Powell, Bart., Physician-in-Ordinary to the King, says:—"But there is a protective influence in the serum of the blood. This resistance to tuberculous invasion is greater in some persons than in others. It is definitely lessened in those descended from a tuberculous stock; it is again lowered by conditions of depressed health from chronic diseases, from evil habits, and from bad sanitation. To all these conditions there is superadded, it is true, a tendency to concentration of infectiousness in surroundings, but an impartial survey of the whole subject renders it quite certain that each of the contributory causes spoken of—heredity, depressed health from chronic diseases, and evil habits—is real and operative in producing vulnerability to an infection so widely distributed as to be practically accessible to all persons."

Sir John M'Fadyen says:—"The compulsory testing of all the cattle in the country, to be followed by the slaughter of all reacting animals, is a plan that no sane and well-informed man could recommend."

Undoubtedly this would be the most effective method of dealing with the disease, but it would be impracticable on account of the cost; one slaughtering would be inadequate to exterminate the ubiquitous specific microbe, and it must not be forgotten that a small proportion of the offspring would tend to revert to the original type. No one understands the elimination of undesirable points better than the intelligent breeder, to whom we are indebted for all available data bearing on the question of heredity in the lower animals.

The following paragraphs are taken from *The Scottish Farmer*:—"Tuberculin at the Perth Sales.—A feature of the sale was the fact that the bull calves from the three expositors had been subjected to the tuberculin test and the results were announced by the auctioneer in every case. In no instance, save perhaps one, could a reacting calf be started above 25 gs., and the cases were rare in which prices at all in agreement with the merits of the animals, apart from the results of the tests, were obtained."

"The cause of this significant change of front on the part of the Northern breeders is said to have been the result of last year's sales. It is currently reported that two of the highest priced bull calves sold last year for export have not gone out of the country. They reacted to the test, and it was useless to ship them. . . .

Hence the fact that almost all the bull calves sold on Tuesday were tested by Mr. Manuel, whose charts were handed over to the buyers when desired and their results announced in every case."

Some advise all calves to be separated from their dams at birth and adequately safeguarded from contagion. This scheme, to my mind, would not be very practical. In order to prolong the safeguarding of these animals they would have to be removed to some lonely island or distant prairie and all the attendants would have to be absolutely free from the bovine tubercle. If it were practical or convenient to continue to safeguard animals which had been removed from their dams at birth, they would not bring enhanced prices for export, as they would be required to mix with cattle abroad, more or less contaminated, and they would neither enjoy immunity themselves nor be capable of conferring any special degree of immunity on their offspring.

The practice, when convenient, of separating calves from their dams at birth and giving them milk only from cows which have stood the test, is to be commended and would be an enormous advantage to the dairy keeper prepared to disinfect his premises and keep nothing but a clean stock, but the plan would be cumbersome in operation as compared with the simple plan of rearing calves only of parents which have stood the tuberculin test after having been duly exposed to the contagion; besides, if put into practice, it would land us no nearer to the ultimate goal—the practical elimination of tuberculosis from our herds.

Seeing that young stock, especially bulls, which have stood the test fetch an incomparably higher price than animals which have not been tested, surely young stock whose parents had also stood the test would fetch a still higher price. Everyone appreciates pedigree, and the longer it is the better. Surely the rearing of such stock, duly registered, would be a money-making business.

At the annual meeting of the Aspatia Agricultural Co-operative Society, Mr. H. Thompson, speaking on the new Tuberculosis Order, which came into operation on the 1st of May last year, said:—"Although a step in the right direction, it does not go far enough, as it only deals with three forms of the disease. The order mostly relates to the udder and milk. There is nothing in the order which empowers the Veterinary Inspector to deal with tubercular disease of the chest—one of the worst forms for spreading the disease—unless the beast is emaciated as well."

At the meeting of the Scottish Sanitary Inspectors' Association in Greenock in June last, Mr. McIntyre, M.R.C.V.S., dealing with the veterinary aspect of the milk supply, said "that the disease by far most prevalent amongst dairy cows was tuberculosis. . . . With each additional year of life the disease increased, so that out of the old milk cows which reach the abattoir an alarming number were found to be diseased."

On the other hand, we find many old, worn-out cows perfectly free from disease owing to the fact that they have inherited power to resist the disease even under long continued unfavourable surroundings.

The Tuberculosis Order is no doubt a step in the right direction. The inspection of meat in abattoirs is admirably carried out; no carcase is passed unless the lesions are purely local, but there is no regulation in force to give reasonable compensation to the butcher. Foreign meat is admitted with portions of the peritoneum removed, as well as all sorts and conditions of meat in the form of sausages.

At a recent meeting of the Agricultural Department, Mr. R. N. Boyd moved a resolution declaring that it would be desirable for the Department to refuse premiums to all bulls which were unable to pass the tuberculin test. Mr. Field seconded. Mr. Field is, I believe, the first M.P. in the British Isles to take this matter up.

He does not go far enough, but if he succeeds in getting in the thin edge the rest will soon follow.

I do hope the Agricultural Department may see its way to set about establishing disease-resisting breeds of cattle, and that the Royal Dublin Society will be the pioneers in giving special awards to classes of animals, male and female, which have been tested and found to have resisted the disease. If the awards were given for bulls only, the disease would probably be lessened by one-third in the succeeding generation, but it would probably take about six times the length of time to eliminate the disease from our pedigree cattle as compared with the practice of giving the awards to both sexes.

When the disease would be eliminated from pedigree stock, the practical elimination of tuberculosis from all our herds would in the ordinary course of events soon follow. Such breeds of cattle would be a boon and a blessing to all, and when exposed for sale would fetch greatly enhanced prices.

J. B. DUNLOP, M.R.C.V.S.

"THE TEACHING OF CLINICAL MEDICINE."

During the last few years there have been occasional evidences in the pages of the medical journals that the belief in the value of clinical study has not been killed out by the developments of laboratory work. Recently the subject has received more attention, and in *The British Medical Journal* of January 3rd there is an address by Sir William Osler; also a long article by Mr. J. Mackenzie, M.D., from which the following extracts are taken. Many of the difficulties encountered and arguments used are similar to those found in veterinary practice.

"I could have illustrated my remarks from other sources, but for the purpose in hand my own experience represents that of the great bulk of general practitioners, and though my attempts to remedy my deficient education may not have been very successful, yet they may serve to convey a knowledge of where the teaching of clinical medicine fails. These experiences refer back to medical education as given thirty years ago, and it will no doubt be contended that enormous advances in education have been made since then. I fully recognise that certain departments, as bacteriology and physiology, have made enormous advances, yet the really scientific teaching of clinical medicine has made little or no advance—in some respects it has retrograded in the sense that the general practitioner is less fitted by his training for the duties of his profession now than he was then. The reason for this is that the teacher of thirty or forty years ago had been a general practitioner, and knew by experience the kind of life the students who would enter general practice would lead, and the aspect that disease would present. Nowadays the teacher is usually innocent of this experience.

On entering general practice I was under the impression that the knowledge of disease was so nearly complete that there was absolutely nothing to be done but to apply that knowledge to my patients. I speedily found that I, at all events, was extremely deficient in my knowledge, for I was continually puzzled by the fact that the majority of my patients presented features widely different from what I had seen in my hospital training. I put it down to my own fault in not having acquired the knowledge, and turned to text-books and visited hospitals in order to improve myself, and took my patients to consultants. Still I made little progress, and after several years it gradually dawned on me that the field of clinical medicine had not, perhaps, been so fully explored as I had thought, and I resolved I

would begin to observe for myself, and take note of every sign or symptom that might appear. I soon found that I was very ignorant of a great many signs and symptoms, some of them very obtrusive, and when I turned to my text-books I found a complete silence on the subject, or a description so little in accord with the facts that it was evident that the authorities did not understand the subject any more than I did. I therefore took courage and laid down a rule that I would not slur over any sign or symptom, but carefully note its presence, try to understand its mechanism and its relation to other phenomena, and to see what bearing it had on the patient's future. Carrying out this idea, I soon came across such a bewildering variety of strange phenomena that it was in vain to attempt to follow them all, so I selected some of the more conspicuous and studied them. But I had scarcely set out on this inquiry when I found that I had to re-educate myself in methods and instruct myself in some of the more simple facts in physiology. I found I had never properly understood the first thing met with in examining a patient, that is, the significance of the statements made by the patient in describing his complaint. I found that in failing to appreciate the significance of the patient's statements, it was not so much a question of the patient's incoherence as of my own ignorance in understanding the condition that gave rise to the sensations. The majority of patients complain because of something that tells them they are not in perfect health. The patient himself cannot very well explain, his recollections are often vague and even misleading. Thus, for instance, the patient would describe attacks of exhaustion and attacks of weakness and of giddiness, and he might vaguely call them heart attacks. A physical examination might reveal no abnormality, and I would be at a loss to account for the sensations. But as I acquired a better knowledge of the heart's abnormal action, I endeavoured to recognise at the same time the sensations that accompanied it. In course of time I acquired a knowledge that enabled me to recognise from the patient's statements the nature of some of the complaints that hitherto I had put aside as of little importance.

"Besides the obscure sensations, difficult to describe, I found that even the most clamant of symptoms—pain—had never really received the attention from clinicians which it deserved. It so happened in my practice that I saw a large number of people suffering from affections of the digestive organs, and my first study was centred on the pain produced by the abdominal organs. By paying careful attention to the pain, the site of its origin, the manner of its radiation, and the circumstances that provoke it, I gradually saw that in this symptom far more information was to be obtained than I had ever expected. But it required great care to get out the facts, and repeatedly the patient's memory was so much at fault that I was baffled. When the pain tended to recur I got him carefully to note all the circumstances. Moreover, as a general practitioner I was frequently summoned to see a patient in great pain, and had the opportunity of questioning the patient while actually suffering. Although I gradually acquired a better knowledge, and was able to adopt a hypothesis to explain the symptoms, it took me a long time to get proofs. Thus the first patient on whom I was able to demonstrate the relation of a gastric ulcer to the pain area, I had watched and studied for ten years. But by pursuing this line of observation in cases of gastric ulcer, and with cases of obstruction in the bowels, and noting the pain as it shifted with diarrhoea, I was able to show that there was an intimate connection between the different parts of the bowel and definite regions in the abdominal wall, so that in certain cases of obstruction, for instance, I would be able to indicate within certain limits the part of the bowel that was obstructed.

This line of observation also enabled me to differentiate the pain due to the digestive tract from the pain due to the other abdominal viscera with more precision than had hitherto been done.

In pursuing this line of observation other phenomena were detected associated with pain. Thus, early in these investigations my attention was arrested by severe cutaneous hyperalgesia in a patient with gall-stone colic. This led me to search for altered sensations, and I found out that hyperalgesia was not an infrequent symptom. But the question arose, In what tissues was this altered sensation present? I was able to test the reaction to simple stimuli of such organs and tissues as the lungs and pleura, the peritoneum, bowel, liver, kidneys, etc., and I found them actually insensitive to pressure, pinching, and cutting.

Other phenomena which I had to investigate presented themselves, such as the reflexes associated with disturbances of other organs. These reflexes not only affected the muscles of the abdominal wall in a peculiar manner, but also affected the activity of other organs sometimes remote from the original seat of trouble. Of these reflexes, that affecting the contraction of the muscle wall of the abdomen presented most instructive features, especially the curious manner in which limited portions of the muscle would remain contracted. It was almost impossible to differentiate these small hard contractions from tumours in the abdominal cavity, and I have repeatedly seen them mistaken for tumours by experienced physicians and surgeons and the abdomen operated to remove them, when no tumour or swelling was found.

My purpose in mentioning these observations here is to call attention to striking clinical phenomena that are to a great extent ignored or misunderstood, and to state that I have repeatedly found these phenomena present in cases which after a long period showed more definite signs of disease, and that therefore this is one of a class of phenomena where we get evidence of a stage in disease earlier than has hitherto been recognised or realised.

"How often do we see surgeons and physicians diagnosing a tender liver, a tender gall bladder, a tender spleen, a tender colon! How do they demonstrate their diagnosis? By pushing their finger into the abdomen in the regions they imagine these organs to occupy. What are they doing? They are pressing on layers of very sensitive structures, and on other structures which are completely insensitive to such stimulation, and describing the pain, not as caused by the sensitive structures, but as caused by the insensitive. Even in such a common complaint as appendicitis, the nature and the meaning of the most striking phenomena present have never been understood, and, so far, I have come across no description of what structures are tender in the most common sign of all—McBurney's point.

Animals (Transit) Order, 1912—Prosecution in Birmingham.

At Birmingham Police Court on Friday, 2nd inst., William Roberts, Bodanedd, Chwilog, Carnarvonshire, was charged with causing three cows to be carried by railway when their condition was such that they could not be so carried without causing unnecessary suffering. Hugh Evans, Gwernallt, Chwilog, was summoned for unlawfully permitting the animals to be so carried. The summonses were issued in accordance with Article 12 of the Animals (Transit and General) Order of 1912. Mr. Kemp prosecuted on behalf of the Birmingham Corporation; Mr. Philip Baker appeared for Roberts, and Mr. Gerald Rigby for the other defendant.

Mr. Kemp mentioned that this was the first prosecution of its kind that had been instituted in Birmingham, and it was one to which considerable importance was attached. The summonses had been taken out under an order of the Board of Agriculture and Fisheries, which was made in the interests of animals which were carried by rail, and which stated "that no animal shall be permitted by the owner thereof, or his agent, or any person in charge thereof, to be carried by railway if, owing to infirmity, illness, injury, fatigue, or any other cause, it cannot be carried without unnecessary suffering during the intended transit by railway."

On November 15 three cows were loaded and sent by the defendants from Chwilog, Carnarvonshire, to Birmingham. Two days later, on the Monday, Inspector Wiltshire, an inspector under the Diseases of Animals Act in the employ of the Corporation, was present at the Fazeley Street cattle siding of the London and North-Western Railway, and there he saw three animals—two black cows and a red and white one. One black cow was dead and the other was in a dying condition, and the third was in a very weak and exhausted state. The following day Inspector Wiltshire visited Chwilog and saw the defendant Roberts, who admitted that he caused three cows to be sent to Mr. Shorthouse, of Birmingham. He said he was not the owner, but he made the statement: "I sent them to Birmingham, and whatever they make I get paid accordingly. It is better for us to send them to Birmingham and chance them passing than killing them at home and having to bury the carcasses." These was nothing, added Mr. Kemp, to show that the animals were being sent for any other purpose than for the food of man. Evans, when spoken to by the inspector, said: "I noticed they were pretty thin."

Evidence was given by Inspector Wiltshire, who said the animals were infirm, weak, and emaciated, and the bones protruded. The animals belonged to Thomas Williams, Tyddyncethin, and Captain Drage, of Bryndy. Their dead weights were: Red and white cow, 279lb.; black cow (found alive), 215lb.; and the other black cow, 299lb. The weight of a healthy, full-grown Welsh cow was about 448lb.

Mr. Baker (cross-examining): The Welsh breed o cows is very small, is it not?—Yes, but very good.

Witness, in answer to Mr. Rigby, denied that the defendant Evans said he had nothing to do with the cows, or that he had no pecuniary interest in them. "He signed the consignment book," added the witness.

Mr. Rigby: You don't suggest he was to share the profits on these poor things?—No, I don't.

Witness added that 17 pigs were also consigned with the cows to Birmingham.

William Hardwidge, a foreman at the Fazeley Street siding, who produced the consignment note accompanying the cows, said, in reply to Mr. Baker, that the animals were received by another foreman named Godslee. The latter made no report as to their condition.

Mr. Baker; Is it the duty of railway servants to look into the trucks to see if animals are fit to travel?—Yes.

Was any report presented in this case?—No.

Mr. Brennan DeVine, veterinary surgeon in the employ of the Birmingham Corporation, gave particulars of his examination of the animals. When he saw them at the Fazeley Street siding he found the two live cows in an emaciated, depressed, and weak condition. The dead cow was merely skin and bone. Later he made a post-mortem examination of the animals. The red and white cow suffered from generalised tuberculosis, it had very bad tuberculous lungs, and suffered from advanced emaciation. The living black cow was ema-

ciated and dropsical, with pneumonia of the lungs, and suffering from John's disease of the bowels. The dead cow was also emaciated, had pneumonia of the lungs, pleurisy, and was suffering from advanced John's disease of the bowels. The animals could not have been carried to Birmingham without unnecessary suffering. They must have been in poor condition long before the witness saw them.

The defendant, William Roberts, then went into the witness-box. He said the two black cows belonged to Thomas Williams, Tyddyn Cethin, and the red and white to Captain Drage, son-in-law of the Lord Lieutenant of Carnarvonshire. The defendant merely acted as an agent of those gentlemen, he being himself a pig dealer. Before the animals arrived at the station the defendant had not seen them. In fact, a veterinary surgeon at Pwllheli had examined the two black cows a few days before they were consigned. The condition of the cows did not arouse his suspicion in any way.

The defendant Evans stated that the truck in which the cows were sent had been hired by him, and when he arrived at Chwilog on the morning in question he found the cattle being placed in the truck. He took no part in loading, and had no interest in the cows. The defendant took no notice of the condition of the cattle.

The Bench found Evans guilty of a technical offence, and he was fined 10s., without costs. Roberts was fined £10 and costs, or, in default, two months' imprisonment. —*Birmingham Daily Mail*.

A NEW TRACHEOTOMY TUBE.

The accompanying illustrations show the working principle of a new tracheotomy tube patented by Mr. J. Young, M.R.C.V.S., of Birmingham. The apparatus is solid, and does not take to pieces for insertion, but is simply introduced into the trachea while the movable projection is turned across the lumen of the tube. A half turn with a key then brings the movable projection outside the lumen, and fixes the tube in position. A plug (which must be removed before the movable projection is turned) and a key are sent with each instrument. Undoubtedly the apparatus possesses two great advantages—viz., that it is extremely light (weighing

1½ oz.), and can be inserted, removed, and cleansed very quickly and easily. Experience alone will show whether its mechanical arrangement is durable in practice, and how it compares with other tubes with respect to the production of granulations.

The tube is supplied in nickel, aluminium, and silver, priced respectively at £1 7s. 6d., £1 15s., and £2 7s. 6d. The silver and nickel tubes can be enamelled to the horse's colour at 5/- extra.

REVIEW.

SPECIAL PATHOLOGY AND THERAPEUTICS OF THE DISEASES OF DOMESTIC ANIMALS. By Dr. Franz Hutyra, Professor of Infectious Diseases, and Dr. Josef Marek, Professor of Special Pathology and Therapy; both of the Royal Veterinary College at Budapest. Authorised American Edition, from the Third Revised and Enlarged German Edition. Translated by J. R. Mohler, V.M.D., Chief of the Pathological Division, United States Bureau of Animal Industry, Washington; A. Eichhorn, D.V.S., Senior Bacteriologist, Pathological Division, United States Bureau of Animal Industry; Dr. P. Fischer, State Veterinarian, Columbus, Ohio; and Dr. H. J. Achard, of the Editorial Staff, *American Journal of Clinical Medicine*. Vol. 1. With 10 plates and 198 illustrations in the text. Pp. xvi + 1133. Royal 8vo. Price £1 11s. 6d. net. (Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden, London).

Our review of Hutyra and Marek's two-volume work has been so tardy in appearing that some explanation is necessary. A review of both volumes had been commenced by the late Mr. Hunting, was laid aside on account of his illness, and overlooked till after his death. This accounts for a delay of some months in the preparation of the review.

As stated above, the present notice concerns only the first volume, which is a very bulky one. It covers infectious diseases, diseases of the blood and of the hæmatopoietic organs, diseases of metabolism, of the spleen, and of the urinary and circulatory organs. The general division of labour has been that Dr. Hutyra wrote upon infectious diseases and Dr. Marek upon organic diseases, each working independently. The first-named author is therefore responsible for the greater part of the present volume.

An English author would probably have published this book under the simple title of "Veterinary Medicine," in place of its present more cumbersome one. Each disease is dealt with successfully as regards its history, distribution, etiology, pathogenesis, lesions, symptoms, diagnosis, and preventive and curative treatment. The work is therefore really an exhaustive treatise upon veterinary medicine, and does not contain much more pathology—as we usually understand the word in England—than every clinician ought to know.

Considering the nature of the subject matter, a translation could hardly have been expected to be up to date on every point. This one is not sometimes, and perhaps the most notable example occurs in connection with John's disease. It is stated on page 639 that all attempts to cultivate John's bacillus and produce specific infection with pure cultures have failed. This was evidently written before the publication of the various European investigations which have put such a new complexion upon the disease within the last two or three years. The text, too, is not free from obvious errors of either translating or proof-reading—for instance, on page 207 we read that cases of distemper in which the nervous symptoms predominate are the "least unfavourable" as regards prognosis. No clinician would agree with this, but the remainder of the sentence and the preceding one show clearly that what is meant is either "most unfavourable" or "least favourable"—which is quite in accord with general experience. Some inequalities and a few errors are inseparable from a work of this description, and their presence need not be dwelt upon. Taking this volume as a whole, it must fairly be pronounced one of the most valuable veterinary works that have ever appeared.

The writing, as a rule, is very clear; and the general arrangement and allotment of space is well judged. The treatment throughout is broad and scientific; opposing views are stated fairly; and the authors, while not afraid of stating their own views, do so without undue dogmatism. Pathological, diagnostic, and therapeutic questions receive almost equal consideration; though the therapeutic portions are often written in a rather condensed form. The tendency is to indicate broad lines of treatment rather than to lay down minute directions. Occasionally classic orthodoxy is consciously abandoned—for instance, Hutyra follows Siedamgrotzsky in the condition usually called contagious equine pneumonia as a pectoral form of influenza, and not a distinct disease. Apart from experimental results, there is certainly much in ordinary clinical experience to support this view.

The longer sections upon the most important diseases are almost invariably admirable; and more than one strikes us as being the best account of the disease it

concerns that we have yet seen. Perhaps the best of all is the masterly article on glanders, which evoked warm admiration from the late Mr. Hunting. The shorter sections upon less important diseases, and the notes upon isolated observations of apparently rare ones, are necessarily not so satisfactory; but we know no comprehensive book on veterinary medicine which is not equally, or more exposed to the same criticism. Taking this volume as a whole so far in veterinary medicine as it goes, we can only call it a long way the fullest and best upon its subject that we know of in any language. No student and no practitioner ought to be without it.

Nearly all the numerous illustrations are good—some very good indeed. The index is useful; but we think that fuller bibliographies, extending beyond the references in the text, would enhance the value of future editions.

Death of Circus Horses at Olympia.

Four horses which were among the animals performing in the circus at Olympia have been taken seriously ill, and two of the number have died in circumstances which indicate that they were poisoned. The two horses died on Wednesday of last week.

The first animal to show signs of distress, a horse named Royale, owned by an Italian family of riders, refused its food after the performance on Tuesday afternoon, became very restless during the night, and died in the early hours of Wednesday. Shortly before midday Siglavi Alda II., a white stallion ridden by Mme. Baptiste Schreiber in her high school riding act, showed similar signs of distress. The horse was removed to a warm stable and received the greatest attention, but died the same afternoon.

The following statement was made by Mr. J. W. Brownless and Mr. F. Hobday:—"The post-mortem examination upon Mme. Schreiber's horse revealed the most intense inflammation of the stomach and intestines, and we have forwarded the contents to the Royal Veterinary College for analysis and chemical examination. We have every reason to suspect a strong irritant poison being the cause."

Mr. Brownless, veterinary surgeon to the circus at Olympia, told a representative of *The Times* that the horses remained standing until within a few moments of death. He did not think that they suffered much pain. A horse with colic usually lost its head and lashed about it violently. The horses at Olympia had been quite passive throughout. They seemed to droop away. The membranes of their eyes became very dark in colour and their mouths showed excoriations. As the victims did not appear to suffer pain it was improbable that the poison was mineral. He had the two horses which had not died in his own stable. They were progressing favourably, and were now out of danger.

Value of Pure Milk.

Hoar's Dairyman (U.S.A.) in a recent issue, provides a striking example of the advantages of a pure milk supply. About two years ago the United States Naval Academy at Annapolis decided that something must be done to reduce the large amount of sickness among the midshipmen. The paymaster in charge of the Academy stores became convinced that most of the trouble was due to bad milk.

The supply was obtained from an adjacent dairy and was found to be about as bad as it could be and still pass as market milk.

It was decided to equip a dairy and produce their own milk. The venture paid in two ways:—the number of sick days among midshipmen dropped from over 1,700 during the year previous to the establishment of the dairy to a little over 300 the first year and a few less the second year of operation; and the two years' experience has demonstrated that under extremely unfavourable conditions they could produce the milk at a price that compared favourably with the previous contract.

This is one of the most remarkable instances on record showing the effect of pure milk. The 800 and more midshipmen were under absolute food control, and all of the factors were known.

OBITUARY

JONATHAN BUNNELL, M.R.C.V.S., Rochdale.

Graduated, Edin: April, 1868.

Mr. Jonathan Bunnell of 57 St. Alban's Street, died under tragic circumstances on Saturday evening last. He had spent the afternoon in company of one of his sons, and returned home about 8.15, it being arranged that his son should call for him later. At 8.30 he was found in a dying condition in his house, having apparently had an attack of the heart. Deceased was 69 years of age, and in his business as a veterinary surgeon had established a good connection. He was a native of Liverpool, and after qualifying in 1868 he started business at Oldham, later removing to Heywood, and ten or twelve years ago coming to Rochdale. He was held in much esteem in the town. Deceased's wife died some years ago, and he leaves a family of six sons.

At the inquest the doctor expressed the opinion that probably the deceased had had a seizure, and sustained the bruises in falling.

The jury recorded a verdict that death was due to natural causes, the Coroner saying it was probable that deceased had been attacked with heart trouble. —*The Rochdale Times*.

ALGERNON LESLIE DAVIES BUNTON, M.R.C.V.S., Betchton Hall, Sandbach. Livrl: July, 1912.

Death occurred on Jan. 4th at Stourbridge, from acute pneumonia, after two days. Aged 31 years.

Communications for the Editor to be addressed 20 Fulham Road, London, S.W.

THE VETERINARY RECORD

JANUARY 17, 1914.

VOL. XXVI.

THE COUNCIL MEETING.

Perhaps the most important feature of last week's Council meeting was the debate upon finance. One member questioned the advisability of so frequently discussing our monetary difficulties in public; but it forces even the most inattentive member of the profession to realise our position—and that position is one that all ought to understand. Little more than eighteen months ago, we sold £1000 worth of Consols. To-day the Treasurer is again faced with a deficit, and a banker's overdraft is being arranged to postpone a further sale; and, when the sale does take place, a great part of its proceeds will be absorbed by the repayment of the overdraft. At present, we can only live by making annual encroachments upon our slender capital; and that cannot go on for more than a few years: we shall not exhaust our capital in two years' time, or in three, so we have still a fair interval before us during which our Bill may be passed.

Perhaps the Bill has a better chance of passing this year than it has yet had, or will have in 1915 or 1916. The coming session may well be less congested than recent ones have been. But after next year's general election—especially, perhaps, if the present Government retains office—we may anticipate a fresh rush of public measures to crowd out private Bills. Failure this year may mean a long postponement, so it will be well for members having influence with M.P.'s to endeavour to use it on behalf of the Bill, as was suggested at the Council meeting.

Little else of moment came before the Council. The chief matters were the Charter, which has finally been adopted with very slight alteration, and the matriculation question, which is to be dealt with once more by a Committee. Both these seem of less immediate importance, compared with the vital question of finance.

THE INTERNATIONAL CONGRESS FUND.

Recently this Fund has made excellent progress. In November the Treasurer was still £700 short of the minimum sum required. He has now obtained the greater portion of this, and a continuance of the present rate of subscribing will soon relieve him from anxiety. Probably there are some members who have deferred subscribing while intending to do so, and their contributions should now go near to completing the amount desired.

THE TRANSMISSION OF FOOT-AND-MOUTH DISEASE FROM ANIMALS TO MAN.

Prof. Cadot, in a communication made to the Academy of Medicine of Paris, reviews the cases of transmission of foot-and-mouth disease to man which have been observed during a period of a century. He confirms the view that it is possible that the affection is conveyed to man by unboiled milk in nearly half of the cases observed, and that direct transmission by contamination of the hands with virulent saliva or the contents of vesicles also occurs. Cases of transmission by whey, butter, or cheese are extremely rare.

Generally speaking, transmission of foot-and-mouth disease to man is far from frequent, and the disease in man is rather rarely a fatal one. Nevertheless, the fact that transmission has been demonstrated justifies the interdiction of the consumption of unpasteurised or unboiled milk. Similarly, elementary precautions on the part of attendants of animals affected with foot-and-mouth are necessary.—(*Annales de Méd. Vét.*)

HYGROMAS IN CATTLE.

Fernand Espony has published (*Le Progrès Agricole*) a lengthy article upon the causes and treatment of these conditions. The most common hygromas in cattle are those of the knee, the point of the sternum, the stifle, and the haunch.

Hygroma of the knee is rather common in cattle. This is explicable by the bovine method of rising from the ground, which involves throwing the whole weight of the body for a moment upon the knee in contact with the ground. From this it follows that the skin of the knees is subjected to frequent scrapings, to rather severe pressure, and sometimes even to blows. If the litter is insufficient, or the ground is unequal or rough, a hygroma develops upon one or both knees. The swelling which constitutes the hygroma is small at first and develops gradually, attaining the size of an egg, of a large fist, or, in some cases, of a child's head. The skin, which at first preserves its normal characteristics, finally thickens and indurates till it conceals the uniform fluctuation which is the most characteristic feature of hygroma.

Hygroma of the knee is not very serious, though in some cases it may considerably impede the movement of the limb. Moreover, if treatment is undertaken, the knee still remains exposed to the same causes which have induced the formation of the hygroma. The author advises that no treatment should be attempted so long as the hygroma remains small, and does not cause lameness. When treatment is decided upon, a variety of methods may

be chosen. Blisters, as a rule, are ineffective. Free incision, or the insertion of a drainage tube or seton may result in cure, but only after a rather long period of treatment, and they necessarily entail suppuration of the opened cavity, which is sometimes the cause of serious complications. Complete extirpation of the hygroma, with removal of a piece of skin and subsequent suturing, is a practicable but a very delicate operation. The best method, in the author's view, is puncturing the hygroma with a fine trocar, aspirating the contained liquid, and finally applying the actual cautery. But even with this method failures and recurrences are frequent.

Hygroma of the point of the sternum may appear in lean animals lying upon scanty litter or irregular ground, or as a consequence of injuring the sternum against the manger when getting up or lying down. If, in the early stages, the animal is placed at liberty in a well littered loose-box, this hygroma will disappear; the application of astringents will aid its absorption. Failing this, the author advises puncture with a fine trocar, aspiration, and the subsequent application of astringents. A large incision is not advisable, for the tissues of the sternal region suppurate easily, and the discharge is very difficult to dry up.

Hygromas of the hind limbs are more common than those upon the fore limbs.

Hygroma of the point of the haunch may occur from violent collisions sustained when emerging from a byre by a narrow door, or from collisions against the wall, which are received by animals stabled at one end of a row of cattle, or from prolonged decubitus. The author recommends the same treatment of puncture and aspiration, followed in this case by an irritant or antiseptic injection (tincture of iodine). The treatment should also include the removal of the cause.

Hygroma of the thigh appears in the neighbourhood of the head of the femur, and results from prolonged decubitus in cases of severe illness. It entails lameness of the limb. The author recommends the repeated application of blisters.

Hygroma of the stifle must not be confounded with arthritis of the stifle. It is due to repeated rubbing, sustained while lying down. As treatment, the author advises puncture and aspiration, with the application of a blister.

Hygroma of the point of the hock corresponds to capped hock of the horse, but has quite a different origin. Most frequently it is due to strokes from the goad, which are often received upon this region. This hygroma suppurates easily, and is accompanied by pain, by intense lameness, and sometimes by tendinous sloughing and gangrene. As the best treatment, the author recommends immobilising the animal upon a suitable and abundant litter, and applying astringents to the region.—*Annales de Méd. Vét.*

ATOXYL IN THE TREATMENT OF MALIGNANT CATARRHAL FEVER OF THE OX.

Wyssmann has published (*Schweizer Archiv.*) an article upon this subject. The treatment of bovine

malignant catarrhal fever has hitherto been unsatisfactory, only producing a good effect in 20 per cent. to 25 per cent. of the cases treated. There has been no lack of agents advocated as specifics, for collargol, iodide of potassium, carbolic acid, creolin, opium, antifebrin, salicylate of sodium, etc., have all successively been recommended and abandoned. Bleeding, so highly extolled by some, has proved inefficacious in the hands of others.

Pericaud, in 1902, reported that he had saved seven cases out of eleven by subcutaneous injections of physiological salt solution. Moussu and others have recommended the same treatment at a later date. Wyssmann, reasoning upon the hypothesis that the disease is a bacterial toxæmia, now advocates disinfection of the blood by means of subcutaneous injections of atoxyl. According to Blumenthal, this agent causes the production of arsenical acids in the blood.

Wyssmann advises preceding the injection of atoxyl by a copious bleeding. He believes that this measure relieves the organism of a considerable quantity of diseased blood, that it favours the rapid regeneration of normal blood, and that it hastens the absorption of the atoxyl.

The technique of the injection is simple. A bleeding trocar of Dieckerhoff's pattern, or the injection needle of a Pravaz syringe, is inserted through the skin of the side of the neck. A caoutchouc tube about five feet long is fitted to the trocar by one of its ends, while the other end bears a glass funnel. By this apparatus two to three litres of a warm 7 per cent. salt solution, into which 10c.c. to 15c.c. of 10 per cent. aqueous solution of atoxyl has been mixed, shortly before the operation, is introduced subcutaneously. A gentle massage of the region rapidly causes the diffusion and absorption of the liquid. The puncture-wound is covered by powdered iodoform or some similar drug.

Wyssmann has obtained very encouraging results from this treatment, and now advocates its extended trial with a view to confirming its efficacy.—(*Annales de Méd. Vét.*)

TUBERCULOSIS IN THE PIG CAUSED BY THE AVIAN BACILLUS.

O. Bang reports (*Maanedskrift for Dyrlæger*) some observations upon this subject. On a farm where there were some tuberculous fowls, numerous cases of tuberculosis were found among the young pigs. The infection, however, was confined to the lymphatic glands of the head and intestine, and had no tendency to invade other organs.

Four fowls and two rabbits were inoculated with tuberculous material taken from the pigs, and all contracted the disease. Three guinea-pigs were then inoculated. These latter showed no lesion at the end of three months, with the exception of one which presented some small tuberculous centres in the lymphatic glands of the flank. The bacillary strain which was isolated from the lesions of the infected fowls showed the classic cultural characters of the avian type of tubercle bacillus.

A second case of transmission from the fowl to the pig has been registered, and Bang also quotes a

case of acute tuberculous pneumonia in the pig, due to the avian bacillus,

Upon both the farms mentioned by Bang, the number of pigs infected was rather large—33 per cent and 66 per cent. respectively.

Two pigs infected with avian tuberculosis were subjected to the intradermal tuberculin test with tuberculin of human and avian origin. Both gave a reaction, but the avian tuberculin acted the most energetically.—(*Annales de Méd. Vét.*)

SUCCESSFUL AMPUTATION OF THE EVERTED BLADDER IN A MARE.

Prof. Coquot records (*Recueil de Méd. Vét.*) the case of a mare which, in consequence of a parturition, suffered from a complete eversion of the bladder. All attempts at reduction failed. Finally, the extremities of the ureters were dissected and fixed by a suture to the internal aspect of the vagina, and the bladder, after an elastic ligature had been placed upon its neck, was removed. The mare recovered in less than a month. The urine was expelled almost every quarter of an hour, the vagina thus playing the part of a reservoir, which was emptied by reflex action produced by stimulation of the vulvar mucous membrane.—*Annales de Méd. Vét.*

[I am not aware that this measure of fixing the ureters into the vagina has been attempted before in veterinary practice. The method of amputating the bladder usually described is to apply the ligature on the fundus side of the ureteral openings, leaving the ureters in position. Unfortunately no further details of the exact procedure followed in this case are available.—TRANSL.]

Royal College of Veterinary Surgeons.

QUARTERLY MEETING OF COUNCIL.

A Quarterly meeting of Council was held at the College, 10 Red Lion Square, London, W.C., on Friday 9th January, 1914. Mr. J. H. Carter, President, occupied the chair, and the following members were present: Col. Sir Francis Duck, K.C.B.; Maj.-General Pringle; Profs. Bradley, Sir John McFadyean, and Mettam; Messrs. Abson, Banham, Barrett, Burt, Clarkson, Garnett, Hobday, Lawson, Mason, McCall, McKinna, Mulvey, Packman, Price, Share-Jones, Shipley, Slocock, Sir Stewart Stockman, Messrs. Sumner, Trigger and Wharam; Mr. George Thatcher, Solicitor; and Mr. Fred Bullock, Secretary.

MINUTES.

The minutes of the last meeting, which had been printed and circulated, were taken as read and confirmed.

The PRESIDENT: Gentlemen, previous to commencing the business of the Council, may I express my best wishes to every member of this Council for a happy and prosperous year. (Cries of "Same to you, sir.")

APOLOGIES FOR ABSENCE.

The SECRETARY announced that the following members had sent letters regretting their inability to attend

the meeting: Maj.-General Thomson, Principal McCall, and Messrs. Dunstan and Lloyd.

OBITUARY.

The SECRETARY read the Obituary List.

DEATH OF MR. WM. HUNTING.

The PRESIDENT: Gentlemen, as President it is my painful duty to propose that a vote of condolence be sent to the relatives of the late Mr. Hunting, our worthy colleague, who served as President of this College, who was also one of our examiners, a gentleman whom I am sure we all greatly respected, and whom the profession mourns. He was a gentleman who travelled far and wide in the interests of veterinary work, at very great expense to himself and very little monetary reward. He was a gentleman who was respected and loved by every one of the students whom he examined. I had the pleasure of his acquaintance for something like a quarter of a century, and he was a gentleman to whom I felt very much attached. He was loved by every one of us, and we greatly deplore his death.

Mr. MULVEY: Mr. President and gentlemen, I second the proposal that a vote of condolence be sent to the family of the late Mr. Hunting. We all knew him. He was held in the very highest respect by every member of this profession. He did his duty to the profession whenever called upon, and his memory will be green as long as the veterinary profession lasts. (Hear, hear.)

Mr. TRIGGER: Mr. President and gentlemen, as one who had known the late Mr. Hunting I think longer than anybody in this room, and probably longer than most members of the profession—because when I was a boy of 16 or 17 I was an articled pupil in the same place where Mr. Hunting was an assistant—I should like to support the proposition. It is a proud and a very pleasant recollection to me that I had 40 years of unbroken friendship with Mr. Hunting. To know the man was to esteem him; to see the way in which his somewhat advanced views in early life matured as he went on; to see the grasp he took of professional matters was to admire the man, and to feel he was an honour to this or to any other profession. Personally, I may say I had a great affection for the late Mr. Hunting. Friends from boyhood are not easily to be replaced. Everything has been said about Mr. Hunting's professional attainments before our Council met. I have read the tributes that have been paid to the late Mr. Hunting, and I have been deeply touched by the kind sentiments that have been expressed. Everyone knows that a wave of regret has gone throughout the profession at his loss. (Hear, hear.) I can only say that I endorse in the highest possible manner the encomiums that have been passed on the late Mr. Hunting. I grieve at his loss, and the profession grieves too. He cannot be replaced, but, as Mr. Mulvey has very truly said, his memory will be green as long as the veterinary profession stands; his memory will be green when very many of us have been forgotten. I wish to add my tribute to the memory of the late Mr. Hunting.

The resolution was passed in silence, all present up-standing.

Mr. MULVEY: Among the list of names that has been read out of those who have passed away since our last meeting is that of a very respected member of the profession, who for some time acted as a member of this Council and as an Examiner; I allude to Mr. William Wilson, of Berkhamsted. He was a genial and kindly man. Many of us knew him intimately, and he served his profession well. I move that a vote of condolence be sent also to his wife and family.

Mr. TRIGGER: I had the privilege of sitting on this Council while Mr. Wilson was a Vice-President when I first came to the Council. I endorse all that Mr.

Mulvey has said, and second the resolution that a vote of condolence be sent to his family expressing our regret at his loss and our appreciation of his services to the profession.

The resolution was carried in silence, all present up-standing.

ADMISSIONS TO MEMBERSHIP.

The SECRETARY read the following list of members admitted to the College since the previous quarterly meeting.

Dublin College. Messrs. Arthur Ernest Brandon, John Reynolds Ellison, St. John Charles Purcell MacFarlan, Edward Spread Mulcahy-Morgan, Daniel John O'Byrne, Henry Mervyn Reid, and James Aloysius Shannon.

Glasgow College. Messrs. James MacLaren Dawson, James McInnes Galloway, and H. McD. Paul.

Edinburgh College. Messrs. A. Whitelaw Carter, John Brodie Russell, and Edward Sewell.

Liverpool College. Mr. Robert Langford Lewis.

London College. Messrs. Arthur Heane Adams, William Percival Sheridan Edwards, Charles Emerson Huston, Guillaume Francois Marais, William Henry Priston, Kenneth Hannam Soutar, Graham Williamson, and Harry Stewart Wright.

CORRESPONDENCE.

The SECRETARY announced that he had received a letter from Mr. E. White Wallis, Secretary of the Royal Sanitary Institute, asking the College to send a delegate to the Congress to be held at Blackpool from July 6th to 11th, 1914, the subscription being one guinea. There would be a Conference of Veterinary Inspectors in connection with the Congress.

The PRESIDENT: Do you wish to send a representative of the Council to this Congress?

Mr. SUMNER: I should think our President might go.

Prof. METTAM: I propose that the letter lie on the table.

Mr. TRIGGER seconded the motion, which was carried.

The SECRETARY: At the last meeting of Council I brought up a request from the Secretary of the Sixth International Dairy Congress at Berne, that we should send a delegate to the Congress next June, the fee being 20 marks. Section 1 of the Congress, Hygiene, deals with "Conditions for the Sanitary Inspection of Milk by Veterinary Doctors," and Section 2 "Is the Systematic Breeding of Cows with a view to the Largest Production of Milk detrimental to their Health and Vitality?" It was moved at the last meeting that this letter be brought forward again at the following meeting of Council.

Prof. METTAM: I beg to propose that no action be taken.

Mr. LAWSON: I second that.

The resolution was carried.

The SECRETARY read the following letter from the Privy Council, dated 14th November, 1913:—"Sir, I am directed by the Lord President of the Council to transmit to you, to be laid before the Council of the Royal College of Veterinary Surgeons, the accompanying copy of a decree recently issued by the Swiss Federal Council, modifying Article 106 of the Federal Regulations for the examination of physicians, dentists, chemists, and veterinary surgeons.—I am, sir, your obedient servant, Almeric Fitz Roy." The minute of the Federal Council, in French, is annexed. It is to the effect that after the first day of November, 1913, practitioners who wish to practise their profession of doctors, dentists, chemists, or veterinary surgeons, in the Federal district must take all the Federal examinations. Those, however, who possess a diploma giving them a right to practise may, by that diploma, obtain a concession on some of the examinations.

Prof. METTAM: I propose that the communication be acknowledged with thanks.

Mr. McKINNA: I second that.

The resolution was put and carried.

The SECRETARY read the following letter from the Education Department of the West Riding County Council, dated December, 1913:—"Qualifying Examinations. Dear Sir,—The West Riding Education Committee have recently had under consideration the desirability of encouraging holders of their scholarships and others to take the fullest possible advantage of the opportunities for further education provided in the secondary schools of the West Riding. To derive any substantial benefit from a secondary school course a boy should attend continuously for at least four years, and the main course is planned to cover that period, commencing at 12. The average length of secondary school life for boys, however, is found to be only 2.5 years. It is thought that one cause of this unsatisfactory circumstance is the low standard of examination still accepted by certain bodies as a qualification for registration or for exemption from a preliminary professional examination. In a number of cases the junior local examinations of the Universities of Oxford and Cambridge, and occasionally the lower certificate examination of the Oxford and Cambridge Schools Examination Board, are accepted as qualifying candidates to commence a course of professional study. The preparation of secondary school pupils for external examinations of this low grade interrupts seriously the progress of school work upon really educational lines. Also a course of professional training cannot, as a rule, be commenced until at least 16 years of age, and in the view of my Committee if a boy of good intelligence has had the advantage of instruction in a secondary school for four years, or until the age of 16, he should have no difficulty in passing an examination of at least University Senior Local, if not matriculation, standard. This being so, it is clearly undesirable that his education should be interrupted to enable him to take an examination of lower grade. No doubt the various professional bodies themselves desire that the standard of their test of a candidate's general education should not be unduly low. My Committee would therefore be glad to see success in any examination of lower than matriculation or "senior local" grade omitted from the list of qualifications accepted by professional bodies. I shall be glad to have in due course your observations on the matter. If you wish for more copies of this circular I shall be pleased to supply them.—Yours faithfully, J. H. Hallam. To Secretaries of Professional Bodies."

Mr. MULVEY: I should like to say that that letter has already been before the Examination Committee, and I propose to read a report on the subject later in the meeting.

The PRESIDENT: It is a most important letter.

FINANCE COMMITTEE.

Mr. LAWSON read the following Report of a meeting of the Finance Committee held on the 9th January, 1914:—

Financial Statement. The Treasurer submitted his Financial Statement for the quarter, showing liabilities amounting to £906 2s. 5d., and a deficit of £35 8s. 6d.

It was resolved (a) That the Financial Statement be approved, and that the Treasurer be ordered to pay liabilities shown, together with monthly salaries, insurance, petty cash, gas, electric light. (b) That the Treasurer be authorised to arrange for an overdraft at the Bank not exceeding £500.

Mr. LAWSON: I beg to propose that the Report be adopted.

Mr. McKINNA: I second that.

Mr. MULVEY: Before you adopt that Report, I hope you are not going to put it on one side without some

consideration. The statement is that we are £35 to the bad, and that I shall be called upon to pay a sum of between £120 and £130 before this Council meets again. You will notice also the Committee recommends that an overdraft be applied for up to £500, for which you will have to pay broadly about 6 per cent. How long is this to go on? You will have to meet this in some way. The value of our Consols now is somewhere about £4000.

Mr. TRIGGER: It was £7000.

Mr. MULVEY: It was more, but now they are nominally worth about £4000. You are putting forward an application for a new Charter which, in round figures, will cost us something like £200 or £300 I think.

Mr. THATCHER: Somewhere about that.

Mr. MULVEY: You keep on spending money and your income is getting less. We hear very little about the new Bill, and I am afraid there is very little prospect of our obtaining it in the near future. This matter must be very seriously considered, and I hope the members of this Council will be able to show us some way out of the difficulty.

Mr. LAWSON: The Committee has recommended a certain course—that Mr. Mulvey can arrange for an overdraft to the extent of £500. I presume that will take us on to March at all events, when we meet again.

Mr. MULVEY: Yes.

Mr. LAWSON: I hope he will bring this matter forward again, because I quite condole with Mr. Mulvey in the way in which he has placed the position before the Council. At the same time we have to pay our way. We may ultimately have to sell some more Consols, but I think until March we shall have plenty of money in hand with an overdraft to the extent of £500.

Mr. SHIPLEY: Unfortunately I was not able to attend the meeting this morning, and I should therefore like to ask the Chairman of the Finance Committee what will be our position after March. If we have got to pay interest on the overdraft at the Bank and then have to sell out our stock again we shall be in a worse muddle than ever. Have you any estimate as to what our position will be after the next examinations?

Mr. MULVEY: The next examinations will not take place until July, and the profit, if we base it on the lines of the last examination, will be somewhere about £290. We made £292 profit last July, but we shall have spent all that long enough before we get to July. You must remember, though, that the net loss on the December examination was £99 18s. 4d., and the examinations are our only source of income.

Mr. SHARE-JONES: Do we understand that the Finance Committee are staking all their cards on this Bill?

Mr. MULVEY: Yes.

Mr. SHARE-JONES: Is it not the function of the Finance Committee to consider some other means of raising money? It is plain to a man with one eye the way in which matters are drifting financially now, but I regard it as the function of the Finance Committee of any body to consider ways and means of raising money, apart from placing entire reliance upon a Bill of which we have been told here this afternoon that there is very little probability of its going through in the near future.

The PRESIDENT: I understood the Finance Committee thought this was the best way.

Mr. TRIGGER: As a member of the Finance Committee, I should like to say that the decision of the whole Council was that our only possible chance was this Bill. I quite agree with Mr. Share-Jones that it is the duty of the Committee to consider the position of the finances of the College, and it is the duty of every member of the Council to consider the position.

Mr. SHARE-JONES: Quite so.

Mr. TRIGGER: It is the duty of the profession to consider the position also, and do all they possibly can to get us this Bill, because there is no question that the position is a bad one at the present moment. We are simply selling our stock and living on our capital, and when that has gone we are bankrupt—that is exactly what it amounts to. In face of this we are spending a great deal more money than we ought to do on the Registration Committee. Then there is another thing—we are going for a new Charter. I entirely agree in every way with the new Charter, but if we are going to be bankrupt in two years' time what is the use of getting a new Charter? It will be waste paper then, and have to be burned.

Mr. ABSON: Who says we shall be bankrupt in two years' time?

Mr. TRIGGER: If the Chairman of the Parliamentary Committee can inspire us with a little more hope, and say that the Bill is in train, then I say, "Go on with your Charter," but at the present time what we ought to do is to put our foot down and spend nothing until we see whether we get this Bill or not. I do not want to throw cold water on the Charter in the slightest, I agree with every word of it, but I think it is premature to go on with it. I think we ought to get our Bill before we get our Charter, because about £300 is going to be spent there. But I do not want to be a drag on the wheel, I do not want to keep the profession back. I quite agree with the new Charter, but I say we have not got the money to pay for it. We are going to pay 5½ or 6 per cent. on the overdraft, and as soon as we have sold our Consols we are bankrupt. That is exactly how we stand. If the profession cannot put their shoulders to the wheel and push the Bill through by means of their local Members of Parliament, this Council cannot carry it through themselves.

Sir JOHN M'FADYEAN: I do not wish to anticipate a discussion which will arise later on a motion at the special meeting, and I also do not want to be sarcastic, but I could not help feeling the utmost surprise when the author of the resolution, which, in my opinion, would precipitate the bankruptcy of this Institution, invites the Finance Committee to advise how that result is to be averted. I refer to the proposal that we should raise the standard of the preliminary examination, and most certainly as a result reduce the number of students by 50 per cent.

Mr. MULVEY: Question.

Mr. SHARE-JONES: That remark has a direct application to myself. The point which is agitating my mind is this, and I should like to know whether the Finance Committee, has considered it. I do not happen to be on the Finance Committee, but on looking through our financial statement it seems to me that the keynote to the whole problem is the question of the examinations. (Hear, hear.) To me again, as an ordinary observer if you like, the solution to the problem is a common centre of examination. I am not pledging myself to the proposal in one way or another, but I should like to know whether the Finance Committee has considered that—the question of a common centre of examination.

Mr. TRIGGER: We cannot do it. We are obliged to hold them at each place.

The PRESIDENT: It would be a very great saving if it could be done.

Mr. LAWSON: I should like to say that the Finance Committee considered the examination question this morning—as to whether we could reduce the expenses in any shape or form. It was fully discussed—I think for three-quarters of an hour—but in the end we apparently could do nothing at present because the examiners are elected at all events for three years, they are elected at stated fees, and at the moment we cannot do anything. But we discussed this matter between ourselves this morning. I believe Mr. Garnett suggests that

there is a possibility of the Bill going through this Session, but Mr. Mulvey is rather of the opposite opinion. Therefore we are divided. If the Bill passes by 1915 we shall get some money in then, but as to getting it from the profession I am afraid we shall not be able to do so.

Mr. McKINNA: I do not think the open Council is the place to discuss so frequently the condition of the College financially. I think we ought to wait at least a little while before saying anything about the finances of the College. I have every confidence, as far as I have studied the thing, that we will surely within another two years get this Bill which we are all longing for, and which I believe the profession generally supports. I do not look upon it that bankruptcy stares us in the face, I am more optimistic than that, and I feel sure when the time does come the profession will rise to its needs.

Mr. BARRETT: What sum of money do you think would be saved if there was one common centre of examinations for England and one for Ireland? (A Voice: We cannot do it.) The point I desired to make was this, that perhaps it might be desirable to embody that condition in our new Charter.

Mr. THATCHER: It is already settled by the Act. Section 4 of the Act says there must be an examination in each country.

Mr. BARRETT: And that could not be modified by the Charter?

Mr. THATCHER: Oh no.

Mr. MULVEY: I should like to say, in reference to what Mr. Barrett has asked, that we should save a considerable sum of money if the examinations were carried out in accordance with the Act, that is to say, that there shall be one examination in England, Scotland, and Ireland. That is all that we are bound to carry out. At present we carry out two examinations in Scotland, two in England, and one in Ireland. If we carried out one examination only in each country it would save a considerable amount in travelling expenses and in fees. I could not tell you exactly how much in round figures.

Mr. BARRETT: Just one thing occurs to me with regard to this financial statement, which I think is most serious. I agree with Mr. Mulvey that we are drifting towards bankruptcy, and I wondered if anything could be done if you, sir, together with certain other members were to approach the Board of Agriculture—if the President of the Board of Agriculture would take up the question for us. I do not know whether any representations have been made.

Sir JOHN M'FADYEAN: Yes, that has been done.

Mr. BARRETT: It occurs to me it might be done. Could those representations be repeated?

Mr. MULVEY: It has been done.

Mr. BARRETT: May I ask if it has been recently done?

Sir JOHN M'FADYEAN: Yes.

Mr. BARRETT: Do you think any good would result if you approached them again?

Sir JOHN M'FADYEAN: May I be allowed, as the Chairman of the Committee in charge of the Bill, to say that we are leaving no stone unturned, there or anywhere else, that holds out any hope. If I may be allowed to refer to this proposal, that there should be one common centre for the examinations for the whole of the United Kingdom and Ireland, I merely wish to say that in my strong opinion that is not a practical proposal. It does not seem to me to be a reasonable proposal that students should be brought from Ireland and Scotland to London or to any other centre in England. You could not find any parallel to that in this country in the case of examining bodies entrusted with powers like ours, and I have not the least doubt that if we made any such proposal the result would be a claim from Ireland

and from Scotland that the time had now arrived for examining their own students, and that is a most serious danger we must be careful to avoid. (Hear, hear).

The PRESIDENT: If there is no further discussion on the matter, I will put the motion that the report of the Finance Committee be received and adopted.

The resolution was put and carried unanimously.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee held on Thursday, Jan. 8th, 1914, at which 24 members of the Council were present. Nineteen cases were considered by the Committee. The Solicitor submitted correspondence he had had with the Local Government Board for Scotland in the case of Leighton, and it was resolved that a further letter of appeal be sent to the Local Government Board, such letter to be submitted in the first instance for approval to a Sub-committee consisting of the President, Sir John M'Fadyean, and Mr. Mulvey.

It was decided that two members should be called upon to appear at the next meeting of the Committee to show cause why their names should not be removed from the Register, the charge in one case referring to the employment of an unqualified assistant.

The Solicitor reported that he had been in communication with the Registrar of Joint Stock Companies in regard to the registration of a company entitled "Veterinary Surgeon Cooke, Ltd." On behalf of the College he had lodged an objection against such a title being registered, and the application had been withdrawn. It was resolved that the action of the Solicitor be approved.

Some cases were ordered to stand over, while others were struck out, and in three cases it was recommended that prosecutions be instituted. The Secretary or Solicitor was instructed with regard to the procedure to be adopted in the remaining cases.

A petition was received from Mr. G. C. Hill, whose name was removed from the Register in 1908 under Section 6 of the Veterinary Surgeons' Act, applying for his name to be restored to the Register of Veterinary Surgeons. It was resolved that the consideration of this application be deferred until the next meeting, the Secretary being instructed in the meantime to obtain further information as to the character and conduct of Mr. Hill during the past two years.

The PRESIDENT: I move that the report of the Registration Committee be received and adopted.

Mr. ABSON: I second that.

The PRESIDENT: Are there any remarks to be made on this report?

Mr. BARRETT: I should like to refer for one moment to the case of Hill. I am aware that this matter received careful consideration by the Committee yesterday, but it did occur to me that there was some confusion in the minds of certain gentlemen present as to what course should be adopted. My friend Professor McCall really intended to move that his name be restored to the Register forthwith, at least after to-day's meeting, but he did not put that specific resolution, and accordingly I think the Council may not have been quite clear as to the decision at which it arrived. You all remember this case. I do not desire to minimise it at all. It was a very serious case—the examination of a certain hackney gelding with regard to insurance, and so on. But what I feel myself is—and I speak only for myself—that the Committee is, in my opinion, acting with undue severity in this case. Hill was a man who had practised for many years in Glasgow, and I think until this lapse he was unquestionably a man of good character, and was respected as a private citizen and as a member of this profession. No doubt

he made a very great mistake : no doubt he was guilty of fraud.

Mr. TRIGGER : I should like to suggest that if we are going to re-open this case we should resolve ourselves into Committee. (Hear, hear). I do not think it is desirable to re-open it ; I put that to Mr. Barrett. But if we are going to re-open it I shall move that we go into Committee.

Prof. METTAM : I second that.

Mr. SHIPLEY : I move that we do not go into Committee. The case has been discussed over and over again, and Mr. Barrett knows nothing whatever about it. He happened to come in yesterday and heard a few words going on, and now he wants to upset all we have done during the last two or three years. There is nothing for us to consider further.

Mr. TRIGGER : If we do not go into Committee you may hold, sir, that Mr. Barrett is quite in order in discussing the matter, and that would make a difficulty. If Mr. Barrett wishes to discuss the matter I shall certainly move that we go into Committee, in fact I have done so, and it is seconded.

The PRESIDENT : And Mr. Shipley I understand has moved that we do not go into Committee.

Mr. SHIPLEY : I move that the question be not reopened.

Mr. MULVEY : I second that.

Mr. BARRETT : On a point of order, sir, I submit that is an unprecedented motion. A member of this Council has an absolute right to express his opinion upon a question of this kind, and upon any question concerning the profession. He has an absolute right to bring the matter before the meeting, and I suggest to you that to put the motion which has been proposed by Mr. Shipley, and seconded by Mr. Mulvey is carrying the thing to the extreme of ridiculousness.

Mr. GARNETT : I would point out to Mr. Barrett, sir, with your leave, that Mr. Barrett is a member of the Committee. He is one of those who strongly advocated that the whole of the Council should constitute the Registration Committee, for the very purpose of thoroughly going into these cases and discussing them freely and openly. I consider that when that has been done, although no doubt he has a technical right to do it, still it is to my mind not in good taste or in the interests of his friends that the case should be re-opened and fully discussed in public.

Sir JOHN M'FADYEAN : May I suggest that we shall probably lose more time in discussing whether Mr. Barrett should be heard than if you put the resolution that we go into Committee. I suggest that you should put that motion now.

The PRESIDENT : I will put the motion that has been proposed and seconded, that the Council resolves itself into Committee.

The resolution was then put and carried.

The Council then went into Committee. On resuming its public sitting.

The PRESIDENT : I beg to move that the report of the Registration Committee be adopted.

Mr. ABSON : I second that.

The resolution was adopted.

Mr. MULVEY : I move that authority be given to the Solicitor to prosecute in the cases mentioned in the report, and that the Seal of the College be affixed to the documents.

Mr. MASON : I second that.

The resolution was carried unanimously.

PRELIMINARY EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Preliminary Examination Committee held on Thursday, Jan. 8th, 1914—

Preliminary Educational Examinations. A revised list of Preliminary Educational Examinations was con-

sidered, and it was resolved to recommend (a) That the present regulations be continued in force until December, 1915 ; (b) That the whole matter of the Preliminary Educational Examinations be remitted to the Committee for consideration and report.

Correspondence. A circular letter with regard to qualifying examinations was received from the Education Department of the West Riding County Council, urging that lower educational examinations should not be recognised as qualifying candidates to commence a course of professional study. The circular was, in general, approved, and ordered to be submitted to the Council.

Mr. MULVEY : I move the reception and adoption of the report.

Mr. TRIGGER : And the circular as approved.

Sir JOHN M'FADYEAN : May I ask what the endorsement of this Council to that proposal means? Does it mean that we pledge ourselves to follow the advice which is given there—that we cease to recognise a number of the educational certificates that are at present suitable ones? I take it that is what is meant by it, and if so I oppose it, because it is contrary to another recommendation which is contained in this report of the Committee. The Council must not decide a question like that off hand. I beg to move that that particular paragraph be deleted, and that we substitute for it, that we decide the communication be acknowledged with thanks.

Mr. MULVEY : I should like to point out that the Committee simply expressed a general approval of the terms of the circular. It was not their intention to carry it any further, in view of the fact that the whole of our preliminary educational work is to be considered at a future meeting. It was simply regarded as the expression of a pious opinion.

Mr. TRIGGER : I shall certainly second Sir John M'Fadyean's resolution, because I think this wording does commit us more or less.

Sir JOHN M'FADYEAN : May I suggest that the phraseology be altered, and that we say we are in sympathy with the suggestion?

Mr. MCKINNA : That is all it means.

Mr. MULVEY : It simply says that "The circular was, in general, approved." What more do you want?

Sir JOHN M'FADYEAN : After the Chairman's explanation I withdraw.

The motion for the adoption of the report was then put and carried unanimously.

EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Examination Committee held on Thursday, January 8th, 1914 :—

Reports on December Examinations. The reports of the Chairman of the Board of Examiners, the local secretaries, and delegates were read and approved.

Educational Certificates. Educational certificates numbered 1372 to 1418 were submitted and approved.

Correspondence. (a) A letter (19/12/13) was received from the University of Bristol with regard to the recognition of the School's Certificate Examination, and it was resolved that the letter be referred to the Preliminary Education Committee.

(b) A medical certificate from Mr. James Mair, who was unable, through illness, to attend the examination at Glasgow in July, 1913, was submitted, and the Secretary reported that he had allowed the candidate to be admitted to the December examination without further payment. It was resolved that the action of the Secretary be approved.

(c) A medical certificate was submitted by Mr. K. S. Simpson, who was unable to attend the December Class C examination in London owing to illness. It was re-

solved that the fee paid be held over until the July examination.

Vacancies in Board of Examiners. The Secretary reported that, owing to the death of Mr. W. Hunting, vacancies were caused in the Board of Examiners for the Membership Degree in the subject of Veterinary Surgery and Obstetrics, Class D, and also in the Board of Examiners for the Fellowship Degree in the subject of Hygiene and Sanitary Science. It was resolved that these vacancies be advertised, and the election of examiners made at the next meeting of Council.

On the motion of Mr. Mulvey, seconded by Mr. Packman, the report was unanimously adopted.

PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Mr. GARNETT read the following report of a meeting of the Parliamentary and General Purposes Committee, held on Thursday, January 8th, 1914 :

Parliamentary Bills. The following private Bills were submitted: Chesterfield Corporation, Preston Corporation, Sheffield Corporation.

The Chesterfield and Preston Corporation Bills contain clauses with regard to the power to exclude old and diseased animals from markets and fairs, which were considered to be entirely satisfactory.

Admission of Women. A report was submitted by the Solicitor with regard to the admission of women to the examinations of the Royal College of Veterinary Surgeons, in which the following opinion was expressed :

1. That as up to the time of the granting of the Charter of 1844, and the passing of the Act of 1881, the students at the Colleges referred to were male students, only such persons were the persons intended to be included.

2. That in addition to, and independent of this, it would be contrary to long usage and precedent to admit women to the veterinary profession.

New Supplemental Charter. A draft of the new Supplemental Charter was submitted and considered.

On Section 6, Mr. Barrett proposed, and Mr. Share-Jones seconded, that in place of the word "teachers" in line 2, the following words be introduced: "teaching institutions and extra-mural instructors in the subjects required for examination for the said diploma." On being put to the meeting this amendment was declared lost.

On the motion of Sir John M'Fadyean, it was resolved to introduce the words "or examinations" after the word "examination" in line 3, paragraph 3, page 4.

It was then resolved that the draft Supplemental Charter, as amended, be recommended to the Council for approval.

Cleaning of Building. It was resolved that this matter be deferred until the next meeting of Committee.

Correspondence. A letter was received from Mr. J. M. Sinclair, containing a copy of a resolution passed at a meeting of veterinary surgeons held at Bulawayo on April 14th, 1913, with reference to the report of the Departmental Committee on the Public Veterinary Services.

The Secretary was instructed to reply that as the Departmental Committee had already reported, the Committee regrets that it cannot take any action on the resolution submitted.

Mr. GARNETT: I propose that the report be adopted.

Mr. SHARE-JONES: I second that.

Mr. SHIPLEY: I should like to raise a question on the Supplemental Charter, where I think a little alteration or addition is perhaps advisable. I should like to ask whether, in regard to the appointment of Vice-presidents, the opportunity might not be taken to indicate who is the senior Vice-president. I believe on previous occasions we have had a little difficulty about

that. Then dealing with another matter, I cannot quite see why it should be necessary to say that a member of the Royal College of Veterinary Surgeons shall have practised his profession for two years before he can take the Fellowship. Assuming a veterinary surgeon after taking his Degree of Membership of the College has the time and inclination to study, why should he be debarred from taking the Fellowship? I think it is quite a reasonable thing that that proviso should be left out. I think we should encourage our members to take the other degree, and should not place any bar in the way of their doing so. I cannot see what good it does, because we know that certain men have gone straight away and acted as teachers in some special subject, and have not what we call practically followed their profession, although they may have done so in some special branch of it.

Sir JOHN M'FADYEAN: That question was raised, and it was admitted by all of us that a member of the profession who spends his time in teaching is practising.

Mr. SHIPLEY: It does not necessarily say so. I am quite in agreement with it, but I think it ought to be made more clear.

Mr. GARNETT: I should like to be allowed to answer Mr. Shipley's first point with respect to the Vice-presidents. I think it is generally felt that some discretion must be left in the hands of the Council for the time being. You can depend upon them to take the proper course of action. After all, they are the body appointing the two Vice-presidents, and they will see that the men who they choose should be the proper Vice-presidents. I do not think it is advisable to tie their hands in the way Mr. Shipley suggests.

The PRESIDENT: I take it it would naturally follow that the one with the longest service would be the senior Vice-president.

Mr. GARNETT: Yes, but I do not want to tie the hands of the Council in any way.

The resolution for the adoption of the report was then put and carried unanimously.

Mr. GARNETT: I now move, sir, with your permission, that the Seal of the College be affixed to the petition as adopted by this Council. I understand that that is necessary.

Mr. MASON: I second that.

The resolution was put and carried unanimously.

ANNUAL FEE COMMITTEE.

Sir JOHN M'FADYEAN read the following report of a meeting of the Annual Fee Committee held on Thursday, January 8th, 1914:—"Veterinary Surgeons Act Amendment Bill. The Solicitor reported that Sir Frederick Low had agreed that the Bill should be introduced in the next Session of Parliament by Mr. Sanderson, M.P., and the Solicitor was instructed to interview Mr. Sanderson with regard to the selection of other supporters of the Bill."

Sir JOHN M'FADYEAN. I beg to move, sir, that that report be received and adopted. I only want to say, in a single sentence, that although of course we cannot give any assurance as to whether the Bill will pass in the next Session of Parliament, I know no good reasons for the pessimism with regard to this point which was expressed by the Hon. Treasurer in an earlier part of the proceedings.

Mr. PRICE: I second that.

The resolution was put and carried.

HONORARY ASSOCIATES COMMITTEE.

Prof. METTAM read the following report of a meeting of the Honorary Associates Committee held on Thursday, January 8th, 1914:—"Honorary Associates. A list of names was submitted and considered. It was unanimously resolved to recommend the following gentlemen for election as Honorary and Foreign Associates of the

Royal College of Veterinary Surgeons: Prof. G. Barrier, Ancien-Directeur, Veterinary School, Alfort; Dr. D. A. de Jong, Director, Public Abattoir, Leyden; Sir Thomas Elliott, K.C.B., Deputy Master of the Mint, London; Dr. F. Hofrat Hutyrah, Rector of the Superior Veterinary School, Budapest; Prof. C. O. Jensen, Director of Serum Laboratory, Copenhagen; Dr. O. Malm, General Director of Veterinary Administration, Christiania; Mr. A. D. Melvin, Chief of the Bureau of Animal Industry, Washington, U.S.A.; Dr. R. Ostertag, Gen. Regierungsrat, Director of Abattoirs, Berlin; Prof. Railliet, Veterinary School, Alfort; Mr. W. C. Schimmel, Substitute-Director of the State Veterinary School, Utrecht; Dr. R. Schmaltz, Prof. of Veterinary High School, Berlin; and Dr. J. Vennerholm, Prof. of Veterinary High School, Stockholm.

Prof. METTAM: I beg to remove the reception and adoption of this report.

Mr. BARRETT: I have pleasure in seconding that.

Mr. HOBDA: Is it possible to add to the list of these men at all?

Prof. METTAM: No.

Mr. HOBDA: It is not possible?

Mr. GARNETT: It is not desirable.

Mr. HOBDA: I do not wish to add a number of names to the list, but there are three names which were originally sent in by myself which at any rate I should like to be discussed. Possibly we might resolve ourselves into committee for the moment, because if they are not elected I would not like to have the matter discussed in public.

Mr. BARRETT: I move that we go into committee.

Mr. SHARE-JONES: I second that.

The resolution was put and carried.

The Council then resolved itself into committee.

On resuming its sittings in public,

Prof. METTAM: I propose that this report be received and adopted.

Mr. LAWSON: I second that.

The resolution was put and carried.

Prof. METTAM: I beg to give notice that these names with their qualifications be suspended on the board for the necessary period of time, and at the expiry of that time, and in due course I will move their election as Honorary or Foreign Associates.

LIBRARY AND MUSEUM COMMITTEE.

Prof. BRADLEY read the following report of a meeting of the Library and Museum Committee held on Friday, January 9th, 1914:—

Presentations. The Secretary reported that since the date of the previous Quarterly Meeting of Council the following presentations had been made to the Library, and it was resolved that a vote of thanks be conveyed to the respective donors:—

Clinical Bacteriology and Vaccine Therapy for Veterinary Surgeons, by William Scott, F.R.C.V.S. A Text-book of Horseshoeing, by A. Lungwitz and John W. Adams. A Description of the Imperial Bacteriological Laboratory, Muktesar: Its Work and Products, by Major J. D. E. Holmes, M.A., D.Sc., M.R.C.V.S. The Carnegie Foundation for the Advancement of Teaching: Medical Education in the United States and Canada. Medical Education in Europe. U.S. Department of Agriculture. Medical Milk Commissions and Certified Milk, by Ernest Kelley. The International Institute of Agriculture; An address delivered by J. G. Rutherford, C.M.G. Memoirs of the Department of Agriculture in India, Vol. 2, No. 2. Statistical and General Report of Army Veterinary Service, 1912. Annual Report of the Civil Veterinary Department, Bihar and Orissa, 1912-13. Annual Administration Report of the Civil Veterinary Department, Madras Presidency, 1912-13. Annual Report of the Veterinary Pathological Laboratory, Nairobi, 1911-12; *The British Medical Journal*, presented by

Dr. Bradley; *The Rhodesian Agricultural Journal* October, 1913; Bulletin of the Yellow Fever Bureau Vol. 3, No. 1; *The Bloodstock Breeders' Review*, December, 1913; *Revue de Pathologie Comparée*, October, and November, 1913; *The Journal of the Board of Agriculture*, October, November and December, 1913; Leaflets of the Board of Agriculture and Fisheries; Orders of the Board of Agriculture and Fisheries; *The Journal of Comparative Pathology and Therapeutics*, September and December, 1913; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter; *The Worlds Carriers* for the quarter.

Purchases. The Secretary reported that the following books had been purchased for the library:—

Tropical Diseases Bulletin, Vol. 2, Nos. 8, 9, 10, 11, and 12; Tropical Veterinary Bulletin, Vol. 1, No. 5; Minerva Jahrbuch der Gelehrten Welt, 1913-14.

Correspondence. The Secretary read letters from the *British Medical Journal* and *The Lancet*, declining to place the Library of the College on the free list.

On the motion of Dr. Bradley, seconded by Mr. Wharam, the report was adopted.

WALLEY MEMORIAL PRIZE FUND.

The SECRETARY: The Examiners for the Walley Memorial Prize Award report that of the four candidates who sat for Examination No. 7 obtained the highest number of marks, namely, Mr. J. F. D. Tutt, Royal Veterinary College of London. The candidates and their number of marks were as follows: J. F. D. Tutt, 186; David Marshall, 184; H. H. Curzon, 179½; W. H. Wortley, 146½.

The PRESIDENT: I move that the report be received and adopted.

Mr. LAWSON seconded the motion, which was carried.

WILLIAMS MEMORIAL PRIZE AWARD.

The SECRETARY read the following Certificate—"List of students gaining 60 per cent. or more marks in the Final Examination:

London, July, 1913: H. W. Dawes 121; R. Daubney 129.
" Dec., " A. H. Adams 121; W. B. Howe 121;
" " G. Williamson 124.

We certify that the above is a correct statement of the marks obtained by the candidates in the Final Year Examinations during 1913, who obtained 60 per cent. or more marks in the subjects of Veterinary Medicine and Surgery. Woodhouse and Wilkinson, Chartered Accountants."

The SECRETARY: The candidate obtaining the highest number of marks is R. Daubney, of the Royal Veterinary College, London, who therefore obtains the Williams Memorial Prize.

The PRESIDENT: I beg to move that the report as read be received and adopted.

Dr. BRADLEY seconded the motion, which was carried.

FELLOWSHIP EXAMINATION

The SECRETARY: I have to report that at the examination held on the 6th December, 1913, the following were admitted Fellows of the College—Messrs. H. Tudor Hughes, H. M. Holland, J. Basil Buxton.

This concluded the business of the quarterly meeting of Council.

SPECIAL MEETING OF COUNCIL.

At the conclusion of the quarterly meeting, a special meeting of Council was held. Mr. J. H. Carter, President, occupied the chair, and the same members were present as at the quarterly meeting.

On the motion of Mr. Garnett, seconded by Mr. McKenna, the minutes of the last special meeting, which had been printed and circulated, were taken as read and confirmed.

MOTION BY MR. GARNETT.

MR. GARNETT: I move the motion standing in my name on the agenda, for the alteration of Bye-law 53.

"That the following Bye-law be adopted:

- 53 (a) *Exemption.* Students who have obtained a Degree in Arts, Science, or Medicine of any University in the United Kingdom, or the Diploma of Licentiate of the Royal Colleges of Surgeons and the Royal Colleges of Physicians, and who at the respective examinations for such Degree or Diploma, have passed in Chemistry and Physics, and also in Biology (Zoology and Botany), are exempted from attendance at the first year's Course of Lectures and from the Examination at the end of that year, provided that each student so exempted shall be examined in the whole subject of Anatomy in the Class B Examination.
- (b) Students claiming exemption under this Bye-law shall, on entering an affiliated Veterinary School, submit to the Secretary of the Royal College of Veterinary Surgeons satisfactory evidence that they are entitled to such exemption.
- (c) Candidates possessing similar qualifications granted by Colonial or Foreign licensing bodies, shall submit their Certificates to the Examination Committee, who shall report to the Council on the eligibility of the applicant for exemption or otherwise."

MR. MCKINNA: I second that.

SIR JOHN M'FADYEAN: I would suggest for your approval it might be convenient to take my motion, which relates to the same thing at the same time. I am quite indifferent as to whether you put mine as an amendment or not.

THE PRESIDENT: Certainly.

That the following bye-law be adopted:—

- 53 (a) *Exemption.* Students who have obtained a Degree in Arts, Science, or Medicine of any University in the United Kingdom, or the Diploma of Licentiate of the Royal Colleges of Surgeons and of the Royal Colleges of Physicians, and who at the respective examinations for such Degree or Diploma, have passed in Chemistry, and also in Biology, Zoology, or Botany, are exempted from attendance at the first year's course of lectures and from the examination at the end of that year, provided that each student so exempted shall be examined in the whole subject of Anatomy in the Class B examination.
- (b) Students claiming exemption under this Bye-law must submit to the Secretary of the Royal College of Veterinary Surgeons, not less than three months before they intend to present themselves for the B examination, satisfactory evidence that they are entitled to the exemption.

SIR JOHN M'FADYEAN: With regard to my own proposal, I should like to point out that it differs from that of Mr. Garnett in two points. Mr. Garnett's suggestion attaches vital importance to the inclusion of both zoology and botany in the subjects embraced by the University degree which the candidate has obtained. It seems to me very questionable whether, if we had any considerable number of graduates for example of Oxford or Cambridge—I mean holding the Bachelor of Arts Degree of those Universities—we should deliberately refuse them this concession on the ground that included among the subjects of their examination there had not been both zoology and botany. I know it may be said that there is a considerable difference between Mr. Garnett's proposal and mine, inasmuch as under his proposal we should ensure that the candidate had studied all the subjects which are embraced in our curriculum, especially zoology and botany. But I only put it forward as my own view that since we have agreed among ourselves that it is desirable to adopt the

recommendation of the recent Departmental Committee, and endeavour to entice University graduates into the profession, we might quite well accept a B.A. or other University graduate, although it appeared that he had not presented himself both for botany and for zoology. Then the other difference between the two proposals is that Mr. Garnett suggests that a student who claims the exemption that is to be accorded to him must do so when he enters an affiliated Veterinary College. Now I confess I am quite at a loss to understand why such early intimation should be given. In the case of the General Knowledge Examination we do not ask candidates to submit their certificates to us until three months before the examination, and it seems to me we should be perfectly safeguarded in every way if we merely required the same length of notice from University graduates who would be exempted from the first year's course of study. Therefore I strongly prefer my own proposal with regard to that point, which is that students claiming the exemption under this Bye-law must submit to the Secretary of the Royal College of Veterinary Surgeons, not less than three months before they intend to present themselves for the B. examination, satisfactory evidence that they are entitled to the exemption. I want to point out that objection may be raised to Clause (b) in Mr. Garnett's proposal, because of its indefiniteness. What is meant by "entering an affiliated Veterinary School?" Does it mean that if a University graduate joined a Veterinary College on the 10th October in any year, and failed from oversight or any other cause to give that intimation during the following eight weeks, he would thereby render himself ineligible for examination in the July following? I think if the substance of his Clause (b) is preferred to mine, then some particular time ought to be specified, and it should not merely say "on entering an affiliated Veterinary School." I beg to move the Bye-law as printed on the agenda paper against my name.

MR. WHARAM: I second that.

MR. GARNETT: I might remind the Council, in reply to what Sir John M'Fadyean has said, of the fact that the only object of either the motion standing in his name or my name is to act upon the recommendations of the Departmental Committee, which strongly recommended that we should offer some facilities for graduates who had taken a science degree. I do not think it matters which, because at the most there can never be any great number; and if a man has taken a Science Degree at any of the Universities we, I feel confident, may safely admit him as having passed our first examination; that is to say, I do not press strongly the point that we should compel every man to have passed both in zoology and botany.

MR. SHARE JONES: What about physics?

MR. GARNETT: That is one of the specified subjects. The only point of difference is zoology and botany, or, zoology or botany.

SIR JOHN M'FADYEAN: I should certainly accept a University graduate although he had not passed in physics, but I think as a rule they pass in physics. I think the amount of physics that the ordinary veterinary graduate gets at the Colleges is so very little that I really should not insist upon it.

MR. GARNETT: It is a matter entirely in your own hands. I have no strong feeling about it at all, because I feel sure that we should be safeguarded in giving these gentlemen the exemption if they have a Science Degree from a University.

SIR STEWART STOCKMAN: What is your idea about Colonial degrees?

MR. MCKINNA: You say in (c) "Candidates possessing similar qualifications." What do mean by that?

MR. GARNETT: I will withdraw my motion.

Mr. BANHAM: Do I understand Sir John to say that supposing a man passed in Arts on classical work only you would admit him and excuse him from our first examination? Supposing a man passes at a University for a parson, and he changes his mind and comes up to the Veterinary College, surely you would ask that man to go through the first examination.

Sir JOHN M'FADYEAN: I should not condemn a man because he had aspirations towards being a parson. (Laughter). I put that entirely aside. To be a parson you do not require to have a University degree at all.

Mr. BANHAM: I said supposing he had studied for that and got his Arts Degree in those subjects.

Sir JOHN M'FADYEAN: But a man cannot get his Arts Degree on theology or anything like that.

Mr. BANHAM: Yes, he can.

Sir JOHN M'FADYEAN: No, I beg to differ. In fact no man gets an Arts Degree on one subject that I am aware of.

Mr. BANHAM: He can specialise.

Sir JOHN M'FADYEAN: Excuse me. In no University in this country, I think, can a candidate get an Arts qualification on one subject.

Mr. BANHAM: Not on one subject, no.

Sir JOHN M'FADYEAN: We should not debar a man from this exemption because theology had been one of his subjects, but he must have the other subjects specified.

Mr. BANHAM: Supposing he knew nothing whatever about botany and zoology.

Sir JOHN M'FADYEAN: Oh no. He must have passed in chemistry and also in biology and zoology or botany in his Arts Examinations.

Mr. BANHAM: Oh, I understood you to say he would be exempt so long as he got an Arts Degree.

Sir JOHN M'FADYEAN: No, I never suggested that. I want to add one point, and that is to mention that it is not only degrees in Science that we propose to accept, because the Universities of Oxford, Cambridge, and Dublin do not give degrees in Science; but nevertheless many of their graduates have presented themselves for precisely the same set of subjects as in other universities would be taken by what are called Science students. I was thinking, for instance, of a case in which a student had taken a B.A. at Cambridge, but instead of taking botany he had taken geology, that is to say his subjects included chemistry, zoology, and geology, but not botany. I really think it would be a little short of a shame to exclude that man when he has aspirations towards joining the veterinary profession.

The PRESIDENT: Mr. Garnett has withdrawn his motion, and it is suggested that I should put paragraph (a) of Sir John M'Fadysan's motion first.

Paragraph (a) of Sir John M'Fadysan's motion was then put and carried.

The PRESIDENT: Now we will take paragraph (b) of Sir John's motion.

Sir JOHN M'FADYEAN: I earnestly hope that Mr. Garnett will accept my clause (b).

Mr. GARNETT: I accept the whole of it.

Clause (b) of Sir John M'Fadysan's motion was then put and carried unanimously.

Mr. GARNETT: I now move that Clause (c) in my motion be adopted.

Sir JOHN M'FADYEAN: I beg to second that.

Sir STEWART STOCKMAN: Is not (c) redundant? I do not object to it, but I understand that many of these University qualifications are reciprocal as regards Home and Colonial Universities, and these men would be qualified according to Sir John's motion.

Prof. METTAM: I think it is as well that it should stand because it safeguards us. It may be that certain of these degrees are accepted by different universities in the kingdom, but it is as well that we should hold

some control, and that we should be able to see exactly what is the nature of these various qualifications. I have great pleasure in supporting the motion that Clause (c) be accepted.

The motion adopting Clause (c) was then put and carried unanimously.

MOTION BY MR. MULVEY.

The following motion was on the agenda paper in the name of Mr. Mulvey:

"That candidates presenting themselves for the First Professional Examination in and after December, 1915, be required to produce a certificate of having passed one of the preliminary educational examinations in accordance with the revised regulations of the General Medical Council, provided that, in the case of candidates whose educational certificates are dated earlier than November, 1914, the present regulations shall apply.

That Schedule I., as revised, be approved."

Mr. MULVEY: As the Council have given instructions that the whole subject of the preliminary educational examination be remitted to a Committee, it only remains for me to ask your permission to withdraw the resolution standing in my name.

Permission was accorded to Mr. Mulvey to withdraw his motion.

Sir JOHN M'FADYEAN: If that is agreed to I want to withdraw, and apologise for the suggestion I made at an earlier stage of the proceedings, that the Hon. Treasurer was anxious to rush the College into bankruptcy.

On the motion of Mr. McKinna, seconded by Mr. Price, a hearty vote of thanks was accorded to the President for his conduct in the chair, which the President briefly acknowledged, and the meeting terminated.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

[NATIONAL V.M.A., IRISH BRANCH.]

A general meeting was held on December 10th, 1913, Mr. P. J. Howard in the chair. Also present Messrs. Heney, Watson, Reavy, Holland, Ebbitt, Kerr, Carr, Magee, Prentice, McKenny, Wilkinson, Norris, McCann, Dodd, Shearman, Griffin, MacClancy, Winter, and Profs. Mettam, Craig, Dunne, and O'Connor.

Minutes of previous meeting, which were circulated with notices of meeting, were taken as read.

Apologies were received from Messrs. Pierse, McGuinness, Small, Purcell, Moffett, and Col. Moore.

The CHAIRMAN: You have heard our Secretary read the correspondence. As to the Victoria Veterinary Benevolent Fund, I think that scarcely needs any recommendation from me. You all know that this fund has been helping the widows and children of several members of the profession here in Ireland, and that up to the present the amount of money subscribed to the fund is not anything like the amount that has been spent on our members. I feel that as Irishmen alone we should feel ashamed of that, and it behoves every one of us to support this fund to the best of our ability. (Hear, hear.) Surely no member would miss even a small donation. Even a small donation would help the fund materially. I hope sincerely that every member of our profession will at once recognise the necessity of subscribing even some small annual sum towards this very good fund.

Then as regards Mr. Garnett's letter in reference to the International Veterinary Congress, I may say that the Congress will be held in London next year. Natur-

ally we are supposed to be as much interested in the matter as are people on the other side of the channel. On reading over the list of subscribers to the fund in connection with the Congress I was really very sorry to see that very few have subscribed from Ireland up to the present, and I hope that this has arisen through mere thoughtlessness, and that this letter will evoke a speedy response. No member will miss a guinea or half-a-guinea, and if all subscribe the fund will be greatly helped.

Then there is a note of Mr. Holland's—that we should take steps to have the question of rebate on petrol considered with a view to getting a rebate allowed to the members of the veterinary profession, as it is allowed to members of the medical profession. I think it is time we did take steps. Of course steps were taken on the other side, and the concession was refused by the Chancellor of the Exchequer, but I consider we have a good case. However, I suppose we must only hope that if we are refused by the present Chancellor of the Exchequer, next year—when we are expected to have Home Rule—this matter will be remedied.

The SECRETARY: This question came before our meeting once before, and I think it was Mr. Walsh, of Carlow, and Mr. Loughran, Aughnacloy, who raised the question with regard to getting a rebate on motor car licences, and on the petrol tax. In consequence of their action we got counsel's opinion, which was to the effect that we were entitled, as medical practitioners, to get licences at reduced fees, and also to get a rebate on the petrol tax.

Mr. WINTER: It is a totally illegal charge, and never should be paid. It is not enforced, and nobody has been prosecuted for not paying it in either Cork or Limerick.

Mr. CARR: Mr. Walsh, of Carlow, was not alone prosecuted, but he was also fined. I do not see why we should not be entitled to the same privileges as regards petrol as the medical profession. Anybody who uses a motor car knows how expensive the petrol is, and most members of the veterinary profession—especially country practitioners—are getting cars. It is one of the first duties of an Association like this to see to matters of this kind. Our President, who has a motor car, will tell you that the petrol bill goes up day after day.

Mr. WATSON: When Mr. Freeman made an application to the Corporation he brought a definite opinion with him and showed it to Mr. Tobin. Mr. Tobin, when he read the opinion, said he was perfectly clear in his mind that we were entitled to a rebate.

The SECRETARY: Mr. Moffatt, of Galway, also got it as a medical practitioner.

Mr. WILKINSON: I got a form from the authorities asking for the dimensions of the cylinders of my car, which I filled in. They then said I was entitled to pay a three guinea tax. I sent on a note that I was entitled to the same exemption as medical practitioners, especially as members of the veterinary profession were recognised as such in the High Courts in Ireland. Eventually they allowed me this half rate.

The CHAIRMAN: As regards Mr. Winter's statement, that the tax is illegal, it so happens that it is a tax supposed to be collected by the County Council. Inasmuch as it is a tax that was not supposed to be pocketed by the County Council or used by them, the notion got abroad that it was an illegal tax. Now since the Road Board has been established the County Council are taking steps to collect that tax. I believe they cannot collect the tax due over several years, but they can collect taxes for the current year.

Mr. WINTER: You will find the whole tax has been repealed in Ireland.

The CHAIRMAN: This is the motor car tax, not the wheel tax.

Mr. WINTER: You will find it applies—the wheel tax applies. Mr. Mahony, of Maryborough, told me he was keenly interested in this question. Would you kindly adjourn it until he comes?

It was agreed to adjourn the matter until Mr. Mahony's arrival.

The CHAIRMAN: The tax is not the serious part of the thing really. Mr. Holland's letter is with reference to a rebate on the petrol tax, which is different altogether from the annual licence you pay on the motor car.

The CHAIRMAN: You had correspondence with reference to the Sanitary Institute.

The SECRETARY: We have a letter here *re* the Congress of the Royal Sanitary Institute. It is a letter simply asking us to appoint a delegate. If we do so we shall have to subscribe one guinea.

The CHAIRMAN: Of course on former occasions we have sent a delegate.

Prof. METTAM proposed that any money to be spent on Congresses should be handed over to the International Congress, and that this letter from the Sanitary Institute be marked "read."

A MEMBER: I beg to second this proposition.

The CHAIRMAN: With regard to the International Congress, I may mention that we have already subscribed to the funds from our Society.

The SECRETARY: Yes, and the Treasurer will have to say whether the funds will permit of another subscription.

Prof. CRAIG: We subscribed £10. Our funds would permit of a subscription of five guineas. Perhaps in the earlier portion of next year we may be able to make up £10, but I think that at the present time it would be better if we only sent over a cheque for £5.

Mr. HOLLAND proposed "That at the next meeting we consider the question of a further subscription to the funds of the International Veterinary Congress."

Prof. METTAM: I second that proposition.

The SECRETARY: I received the other day some veterinary literature in the form of pamphlets from Prof. Perroncito, of Turin. The pamphlets are printed in Italian. Prof. Perroncito deserves the thanks of this Association for sending us these pamphlets. I propose a resolution to this effect.

The CHAIRMAN: What is the nature of them? What is the object of sending them?

Prof. METTAM: Might I say that Prof. Perroncito is an hon. member of our Association.

The CHAIRMAN: I am sure we are unanimous in thanking Prof. Perroncito for these communications.

The SECRETARY read the following:—

REPORT OF COUNCIL.

A meeting of the Council of the V.M.A.I. was held at the Veterinary College, on Tuesday, Nov. 11th, 1913, at 5 p.m. There were present: Mr. P. D. Reavy in the chair, and Messrs. Heney, McKenny, Mahony, Wilkinson, Magee, and Profs. Craig and O'Connor.

The minutes of the last Council meeting were read, confirmed, and signed.

Apologies for non-attendance were received from Messrs. Howard, Patrick, Dunlop, and Prof. Mettam.

A postcard was received from Mr. Holland asking that rebate on petrol be put on agenda for general meeting. Agreed to.

Letter received from Mr. Shipley asking for renewal of subscription to Veterinary Benevolent Fund. Proposed by Mr. McKenny, and seconded by Mr. Mahony, and passed, that last year's subscription be repeated.

Letter received from Mr. Garnett with reference to further subscription to International Congress Fund. Ordered to be brought before the general meeting.

Letter from Mr. Howard to be brought before the

general meeting with reference to wreath for Mr. Hunting's funeral.

Nomination. Mr. Luke P. Knight, of Enniskillen, was proposed by Mr. Reavy, and seconded by Mr. McKenny.

It was arranged that the general meeting should take place at the Veterinary College, on the evening of the first day of the Winter Shows, at 7.30 p.m., Prof. Craig to read a paper on "Sarcoptic mange in the dog," illustrated with lantern slides and specimens.

With reference to the annual dinner, it was resolved that evening dress should be worn.

The HON. TREASURER reported that a large proportion of the members of the Association had not paid their subscriptions, some of them for years, and wished the Council to decide what action should be taken in the matter. It was resolved to bring the matter before the general meeting.

Mr. CARR complained that the Association had not met in accordance with the rules.

The CHAIRMAN: In this matter, I suppose, I am probably the guilty party. When Prof. O'Connor wrote to me about the meeting I simply suggested that the first day of the Winter Show would be the proper time to have the meeting instead of November. I am sure the members present will accept this explanation.

From the report of Council you will see that it is suggested that a further subscription be sent to the Veterinary Benevolent Fund. I take it that the amount will be similar to that subscribed on former occasions.

THE LATE MR. WILLIAM HUNTING.

The CHAIRMAN, referring to the death of Mr. Hunting, said it will be our duty to send a vote of condolence to Mr. Hunting's relatives. Though not a member of the Association he was a friend of the Association and of the various members of the profession here in Ireland. We are all aware of the good work that he did on behalf of the veterinary profession. He was one of the pillars of the profession, and never spared himself in any way in advancing its interests and those of veterinary science. He was a man to whom we must all look up to as an example to be followed. I wish to propose a vote of condolence which our Secretary will send to the late Mr. Hunting's relatives conveying our sympathy in their bereavement.

Prof. METTAM: I have the melancholy pleasure of seconding the motion from the chair, which places on record the very severe loss which the profession has sustained.

The motion was passed in silence, the members standing.

Mr. REAVY proposed a resolution expressing their deep sense of the loss sustained by the death of Mr. John A. Thompson, of Lurgan: "We, the members of the Veterinary Medical Association of Ireland place on record our high appreciation of the late J. A. Thompson, F.R.C.V.S., of Lurgan, a distinguished member of our Association and profession; and we express our deep sense of our loss. His genial manner and wisdom endeared him to us all as a good friend, and his great professional knowledge and skill were ever helpful to us all in our everyday work. We tender to his wife and family our heartfelt sympathy in the hour of their sore affliction.

Mr. WINTER seconded. He said that the late Mr. Thompson was a personal friend of his, as indeed he was of most of them there that evening. They all knew what he was, how keen he was in his professional work, and what a good friend he was to his professional brethren.

The motion was passed in silence.

Mr. MAGEE: May I mention the death of another colleague recorded in the papers this morning—Mr. O'Reilly, of Navan, who was a member of this Associa-

tion at one time. I should like to propose a vote of condolence, and that we should send a letter of regret to his father, Mr. Laurence O'Reilly, of Navan, expressing our regret at his loss.

Mr. McKENNY seconded the motion which was carried in silence.

The CHAIRMAN: The next business is to ballot for candidates for membership, already proposed and seconded.

After the ballot the Chairman announced that Messrs. KNIGHT, DOLAN, and O'BRIEN had been elected members of the Association.

MOTOR CARS AND PETROL.

A telephone message was received from Mr. Mahony saying he missed his train.

The CHAIRMAN: We may now discuss the question of the rebate on petrol.

Mr. WINTER: I beg to propose that the matter be referred to the Council to take action. This is a matter of some importance to a good many of us, and I think it is high time we should go thoroughly into the question of the tax. The High Court has declared that we are medical practitioners. If so we should claim the privilege we are entitled to. We are exempt from juries, and we should insist on our rights in this particular too. I was informed by a legal man of some standing that the tax was an illegal tax. But I think the best thing to do is to refer the whole matter to the Council.

Mr. HOLLAND: It is very hard to get a full meeting of the Council together. I called some attention to this matter in a couple of short letters, and Mr. Mahony wrote one in reply. I am glad to find that you are in entire accord with the views I hold myself and I think it only remains now for us to take counsel as to the best method of accomplishing the objects in view. I am not aware whether, when the question of the tax arose, the medical profession were mentioned in the Act of Parliament.

Mr. WATSON: They are.

Mr. HOLLAND: Then we will have to have recourse to the Law Courts, as Mr. Allen did. Did you get counsel's opinion at that time Mr. O'Connor?

The SECRETARY: Yes.

Mr. HOLLAND: Is Mr. Walsh, of Carlow, still a member?

The SECRETARY: Yes.

Mr. HOLLAND: Well, he complained at the time. I asked a young member of the profession was he not a member, and he said no, as we had done nothing for Mr. Walsh when he was fighting the County Council. I said we feed counsel, and I am very glad to see I was right. If necessary I think we should approach the Chancellor of the Exchequer through our Members of Parliament. In what way did our English friends fail?

The CHAIRMAN: When the tax was first proposed it was to be a general tax. Then the medical profession approached the Chancellor of the Exchequer and got him to give a rebate, on the ground that they were taking up a humanitarian position in going to save life. On the strength of that the veterinary profession in England sent a deputation. We have no business in going to the Chancellor of the Exchequer. If we hold on to the fact that we have been recognised as medical practitioners in our own country we might succeed.

Mr. HOLLAND: Would not it be well to approach the Chancellor of the Exchequer first?

The CHAIRMAN: They have approached him in England and he has refused them.

Mr. HOLLAND: England is a rich country. If we agitated we should probably succeed.

The CHAIRMAN: It might be dangerous, having regard to the fact that he has already refused our profession in England.

Mr. HOLLAND: We are working too for the preservation of human life, in stamping-out the "white plague," and I think that should be a good excuse for us.

Mr. CARR: I suggest that as the veterinary profession in Ireland have so much to do in connection with public health matters and as we are of so much use to the public at large, that the same facilities should be given to us as to the medical profession. We did not know at the time that the Revenue authorities had recognised the medical profession in the licensing of cars. Now, I am sure that armed with the authority of the Inland Revenue, the Chancellor of the Exchequer would give us the same advantages as the medical profession, because they have admitted we are on the same grounds as the medical profession. I don't think we should have any difficulty in this matter. I would suggest that a committee of members of our organisation should see the Dublin Members of Parliament. I do not think it would embarrass the Government in any way, because now the policy is "full steam ahead."

Mr. REAVY said that the Revenue authorities had nothing at all to do with the licensing of cars. It was the County Councils.

Mr. WILKINSON: I know that mine has to be paid at the post office.

Mr. REAVY: I know a man in County Donegal who got a refund through the County Council.

Mr. CARR: You can pay through the County Council or through the Post Office. When the Automobile Club have a grievance about road they advise members not to pay taxes in that particular county.

Mr. WINTER: The taxes will be enforced in the particular county in which you reside.

Prof. CRAIG: I think the discussion is going away from the point. The question before us is, how we are going to get a rebate—how can we claim it, and how can we insist on it? The only way we can see this is to have a test case arranged. If a test case is arranged, a certain amount of money will be necessary, and I don't think the Association is in a position to supply a sufficient amount of money to carry on a test case. The only way is by forming a substantial sum for the purpose. There is no reason, if it would pay car owners who are veterinary surgeons, why they should not raise a fund amongst themselves. For that purpose I would propose that a small committee be formed, including Mr. Holland, Mr. Reavy, Mr. Mahony, Mr. Wilkinson, and Mr. Howard, to make arrangements with reference to that point.

Mr. REAVY: I think it would be a one-sided arrangement to select only the owners of cars. This is a matter that concerns the whole profession.

Mr. WATSON said he desired to second Prof. Craig's resolution.

The CHAIRMAN: I am sure that Professor Craig does not mean that all the expense should come on people who own motor cars. He merely suggests that people who own motor cars should at least start the fight, and we will see that any expense incurred is made up for them.

Mr. CARR said that as far as the dignity of their profession was concerned, they wanted to be on the same standing as the medical profession.

Mr. HENEY: I am not a motor car owner, but I want to say this—I understand that the High Court has, thanks to Mr. Charles Allen, classed us as medical practitioners. The medical practitioners have at the present moment obtained a rebate on petrol of, I think, 1½d. a gallon. Speaking recently to a manager, I asked him would I not be eligible for a rebate on the petrol consumed, and he said "yes, if you buy petrol. I will certify you bought so many gallons of petrol. Present that at the Custom House, and you will be allowed a

rebate." If we are recognised, surely we are entitled to a rebate without going into committees.

The SECRETARY: We have counsel's opinion here, and I think it clears up the matter very well. There is no doubt as to being entitled. That is what Mr. Fottrell, solicitor, told Mr. Freeman, when Mr. Freeman, in applying for his licence, sent it in and got it as a medical practitioner. Mr. Moffett got a rebate on the licence.

Mr. HENEY: Can we hear counsel's opinion?

The SECRETARY: I may say in regard to the suggestion of Professor Craig that Mr. Mahony the other day stated here that he, as a motor car owner, was prepared to stand in and bear the expense with other owners of having a test case.

Mr. NORRIS said he thought it unwise to go into that too much. They might have a reverse such as the Royal College of Surgeons got quite recently.

The CHAIRMAN: This is the last meeting of this year, and at the next meeting—which will be the annual general meeting—there will be the important matter of the election of the various officers. Now a number of members of the Association don't take the interest they ought to in this question of the election of the officers. The rules provide that during this month of December if any member of the Association wishes to nominate any other members, either as President or member of the Council of the Association, he shall make that nomination during this month of December. I simply wish to remind you that it is your duty as members of the Association to take an interest in the business, and if you think there is any alteration required in the personnel of the various positions you should nominate the persons you think ought to be in those positions and send them in to the Secretary.

Mr. WATSON: We must also obtain the consent of the members that they will act in the positions.

The CHAIRMAN: Yes, that is so; but I just wished to point out that the time is at hand for making the nominations.

Mr. CARTER: May I be permitted to thank the members for having been privileged to be present at your meeting to-night. I am specially grateful to Prof. Craig for his excellent paper on a most interesting subject. It is a pleasure to us, who come here as visitors from time to time, to find that we always get that welcome and hospitality for which Irishmen are proverbial. I wish to express thanks to the gentlemen who have so kindly entertained me—especially Prof. Mettam—during my visit here. (Applause.)

The CHAIRMAN: I am only sorry that the Irish Channel prevents Irishmen and Englishmen from having more frequent interchanges at our meetings.

Professor J. F. CRAIG, M.A., M.R.C.V.S., then read a paper on "Sarcoptic Mange in the Dog," which was illustrated by lantern slides and specimens. [This paper will appear later.]

LANCASHIRE VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH].

The quarterly meeting was held on Thursday, December 11th, at the Grand Hotel, Manchester, the President, G. H. Locke, Esq., in the chair. The attendance included Messrs. Hopkin, Lawson, Hughes, Ellis, Lloyd, Taylor, Holroyd, W. G. Burdred, Dobie, A. M. Munro, Bridge, Wolstenholme, Noël Pillers, Richmond, E. J. Burdred, Campbell, Stent, Packman, Wilson, Walker, Darwell, Mattinson, Carter, C. L. Smith, Michaelis, Ingram, Rankin, Whitehead, Spruell, and Brittlebank,

Visitors: Messrs. Halstead, Facer, Menzies, Torrance, Finch, Curbishley, and W. J. Young.

Apologies for absence were received from Messrs. Hughes, Hobday, Abson, McKinna, and Wharam.

Minutes.—The minutes of the last quarterly meeting were taken as read, being proposed by Mr. Lawson, and seconded by Mr. Carter.

THE LATE MR. WM. HUNTING.

The **PRESIDENT**: before opening the proceedings referred to the sad loss which the veterinary profession had sustained by the death of Mr. Hunting. Unfortunately the Association did not know in time to arrange for representatives to attend the funeral nor to send a floral tribute.

Mr. CARTER said it was with melancholy feelings that he rose to propose that they should send a letter of condolence to the family of the late Mr. William Hunting expressing sincere sympathy and regret on their loss. Mr. Hunting was well known by every member, and was a pillar in the profession. He spent much time travelling about the country attending meetings, and also contributed repeatedly to veterinary literature. He (Mr. Carter) had been associated with Mr. Hunting in examination work, and it was noticeable by the kindly manner in which he dealt with students coming before him how endeared they were to him.

Mr. LAWSON, as an old friend of Mr. Hunting, also spoke of his life-long association with the deceased, and said no better man ever entered the profession.

The resolution was passed in silence, all present standing.

Nominations. Mr. E. H. CURBISHLEY, Alderley Edge, and Mr. RUTHVEN, New Mills, were nominated for membership by Mr. Brittlebank, whilst Mr. Packman nominated Mr. CHAS. BLACKHURST, Preston.

Elections. Mr. J. D. RANKIN, Colne, was unanimously elected a member of the Association, on proposal of Mr. Locke, seconded by Mr. Brittlebank.

Tenth International Veterinary Congress, 1914. The **HON. SEC.** read a copy of a circular letter which had been sent to the members of the Association and members of the profession resident within 50 miles of Manchester, excluding Yorkshire, inviting subscriptions towards the expenses of this Congress, and expressing the hope that the Lancashire V.M.A. would do as well in this respect as any other Association in the country.

Election of Council R.C.V.S., 1914. The **PRESIDENT** reported that the Council of the Lancashire V.M.A. had duly considered this matter and came to the conclusion that they had a good nominee in Mr. Brittlebank, and recommended that he be adopted. He proposed that this recommendation be confirmed. Mr. Carter seconded.

Mr. HOPKIN, in supporting, said that, if elected, Mr. Brittlebank would be an acquisition to the Council owing to his practical knowledge of the needs of the profession and, in particular, certain aspects of it.

Mr. BRITTLEBANK, in thanking the members for their promise of support, said that if successful he would endeavour to uphold the honour of the profession, and particularly that of the north.

The **HON. SEC.** reported the receipt of a letter from the Yorkshire V.M.A. intimating that Mr. A. Mason would again be their candidate and inviting support. The Lancashire V.M.A. usually combines with the Liverpool University, Yorkshire, and Eastern Counties V.M.A. for electioneering purposes, and the Council suggest that this procedure be again adopted. Mr. Wolstenholme proposed, and Mr. Taylor seconded, that this be done. Carried.

Annual Dinner. The **SECRETARY** said the Council recommended that the annual dinner be held as usual, under the conditions existing last year, viz., that

ladies be invited. It was proposed by Mr. Pillers and seconded by Mr. Carter, this recommendation be approved. Carried.

ELECTION OF OFFICERS.

President.—Mr. TAYLOR, in addressing the members said he did not address the present occupier of the chair because he intended asking them to re-elect Mr. Locke to the office so well filled by him during the past twelve months. It was argued that honours should go round, but they had not a large membership, and Mr. Locke had only just served his apprenticeship as President, though he had a long innings as secretary of the Association. The Society had prospered under his régime, and he (Mr. Taylor) looked forward to another prosperous year.

Mr. WOLSTENHOLME seconded the proposition, and it was approved.

Mr. LOCKE thanked the members for a renewal of the honour conferred upon him.

Vice-presidents.—The Council recommended the names of Messrs. ACKROYD, NOEL PILLERS, and J. WRIGHT. This was proposed by Mr. Wolstenholme, seconded by Mr. Carter, and carried.

Hon. Treasurer.—Mr. Lloyd thought they could not do better than re-elect Mr. STENT, who was working hard in the interests of the Association. He proposed Mr. Stent, and Mr. Wolstenholme seconded.

Secretary.—The President expressed pleasure in proposing that Mr. BRITTLEBANK be re-elected. Mr. Lawson seconded.

Hon. Auditors.—Mr. W. A. TAYLOR and Mr. J. SPRUELL were appointed, being proposed and seconded by Mr. Pillers and Mr. Hopkin respectively.

Council.—There were submitted:—The President, Vice-presidents, Hon. Treasurer, Hon. Secretary, and Auditors, together with Messrs. J. Clarkson, J. Hopkin, A. Lawson, J. McKinna, A. Munro, sen., W. Packman, H. Sumner, J. B. Wolstenholme, and W. Woods.

Mr. CARTER proposed that these be elected as Council, and Mr. Burndred seconded.

"SOME DIFFICULTIES IN THE DIAGNOSIS OF DISEASE IN ANIMALS IN OPEN MARKETS."

J. D. WHITEHEAD, F.R.C.V.S.

The veterinary inspection of live animals exposed for sale in auctions and cattle markets has been carried on in a more or less unsatisfactory manner for many years.

1. It may be divided into two sections, viz., the inspection of animals under the Diseases of Animals Acts, and the various Orders made by the Board of Agriculture.

2. The inspection of such for the protection of the public health in the prevention of the sale of diseased animals intended for the food of man.

Under the first heading it may be remarked that where a veterinary surgeon has been appointed to inspect a market it is chiefly for the purpose of inspecting pigs, with a view to the detection of swine fever, and nothing further is done. This applies to the majority of markets, and it may be remarked here that the Diseases of Animals Acts do not make it compulsory for a local authority to have a veterinary surgeon present at the live stock markets.

For many years past the inspection in the Salford cattle market has been in the hands of veterinary surgeons, who have not confined their attention entirely to the inspection necessary for the purposes of the Board of Agriculture Orders, but extended the scope of their activity and endeavoured to detect diseased conditions such as might be dangerous to man from the food aspect. It may be of interest to state that the

Salford cattle market is the largest in Great Britain, the number of animals exposed for sale average weekly 2000 cattle, 12,000 sheep, besides calves, and a very few pigs.

The importance of the inspection of markets is considerable, and additional attention was drawn to the value and necessity of the work by the issue of the Tuberculosis Order of 1913.

My experience in the inspection of a cattle market has shown me that there can be no half measures—that an official must take a firm stand, make full use of his legal powers, and be prepared to face considerable opposition. Lax inspection for a week or two and the dealers take advantage of it—with a marked increase in the number of cattle of a doubtful class.

Before proceeding further, it may be of interest to state the legal powers under which such inspection can be carried out. They are contained in Section 116 of the Public Health Act 1875. "Any Medical Officer of Health or Inspector of Nuisances may at all reasonable times inspect and examine any animal, carcase, meat, etc., exposed for sale or deposited in any place for the purpose of sale, or of preparation for sale and intended for the food of man, the proof that the same was not exposed or deposited for any such purpose, or was not intended for the food of man resting with the person charged, and if any such animal etc. appears to such medical officer of health or inspector of nuisances to be diseased, or unsound, or unwholesome, or unfit for the food of man, he may seize and carry away the same himself, or by an assistant in order to have the same dealt with by a Justice."

You will observe that the fact of being a qualified veterinary surgeon or a veterinary inspector to the local authority does not qualify him to perform the duty of inspecting animals, and that it is necessary for him to be appointed an Inspector of Nuisances. This want of recognition of the qualification of the veterinary surgeon in the Public Health Act is a matter that the Royal College of Veterinary Surgeons or the National Society should keep in view when a new Public Health Act comes to be drafted. Many veterinary surgeons may be of the opinion that it would lessen their professional dignity to be so appointed, but it gives one greatly increased powers, and enables a veterinary surgeon to take action without going for the aid of the Medical Officer of Health—who is probably totally ignorant of the subject, or of the Inspector of Nuisances—who is usually keen on getting the credit for doing the work. There has always been some difficulty in taking action with live animals under this section of the Public Health Act. The dealer in questionable animals knows the law—usually from experience—and not an uncommon plea is to be told that the animal was for "store" purposes. In the past my action was to wait until I observed a butcher bidding, and then to threaten seizure with its attendant penalties, if the owner did not immediately slaughter and give facilities for the inspection of the carcase. Of course one has always to bear in mind the question of illegal seizure and the consequences thereof, but where the animal is slaughtered by the owner's directions, no question of illegal seizure can arise. The point of view I have always upheld to owners of suspicious animals was, that if sold alive they would only get a gambler's price from a butcher, whereas if such animal were slaughtered and the carcase, or any portion of it, passed, this would realise its full market value, and perhaps more than the live animal.

The Salford market is chiefly a butcher's market, and the animals exposed for sale are mostly fat ones. The cattle—principally bullocks and heifers—are Irish, Welsh, Norfolk, and Scotch, in the order mentioned. A fair number of fat barren cows are shown, being brought from Cheshire, North Wales, and Staffordshire,

and it is amongst these one expects to get the most of one's public health work. A few fat bulls are also brought from the same district.

Sheep are Irish, Welsh, Lincolnshire, and North Country, from the Carlisle and Border Counties.

Recently a market in newly-calved cows has been established, and about 100 of these are shown weekly, they are principally Irish, and are of all ages. A few store cattle are also brought, and the difficulty is that these animals are not confined to a special part of the market.

The majority of these animals arrive in the borough by railway, and accidents and death during transit are not infrequent. The causes of death in transit are often obscure, and one is frequently called upon to give a decision in these cases. Accidents giving rise to broken limbs, broken horns, lameness, etc., are frequent, and each case has to be dealt with on its merits. Serious injuries are often caused by cattle horning each other in transit, my experience being that the most serious injuries are chiefly in the flank, and may cause a rupture of the abdominal wall.

The methods of diagnosis in live markets are limited. One has to rely on sight and touch; percussion and auscultation are not practicable. A knowledge of the districts from which the animals come, and the disease most frequently met with in animals from these districts plays a very considerable part in one's success—or otherwise—in diagnosis.

The diseases most commonly met with are tuberculosis, John's disease, actinomycosis, and parasitic conditions.

Tuberculosis is not an easy condition to diagnose at any time, the pitfalls are numerous, and symptoms are often indistinct. The diagnosis of tuberculosis of the lungs, in great part depends on the character of the cough that one can excite by compression of the larynx—a weak, paroxysmal, non-expulsive cough gives one a great feeling of confidence, and an animal with a barrel-like thorax, with fixed ribs and abdominal breathing, is usually in the same category. I am always suspicious of an animal with marked tympany, and when one comes to enquire into the history of such a case one often learns that it is a constantly recurring condition; such cases are often due to enlargement of the mediastinal lymph glands.

Tuberculosis of the udder one used to meet fairly often, but of late it has become rarer. Since the 1st of May, 1913, I have detained 17 cows with indurated udders, 11 of these proved on post-mortem examination to be tuberculous; and six were not. All of these were advanced cases, and were probably cleared off the farms because the owners realised this fact. I have no doubt, of course, that many animals have been through the market affected to a less degree and were not detected. Inspection is at all times of secondary importance to business and one cannot get every cow tied up or held, to afford a proper examination of its udder.

Brain symptoms due to tuberculosis are of interest and great help in the examination of young cattle.

I am not aware of any one who endeavours to diagnose tuberculosis of the bowels and mesenteric lymphatic glands in animals in markets by rectal examination, and it would be a source of amusement to cattle dealers and drovers if one attempted it.

Enlargement and induration of the superficial lymphatic glands or a "snorer" are great aids. The chief lymphatic glands to examine for this purpose being the submaxillary—parotid and pre-scapular; but it is easy to imagine one in handling an enlarged lymphatic gland and on post mortem to find that the same gland is normal in size and consistency.

Tuberculosis of the eye is rare, but a lesion well worth bearing in mind: and the same value attaches to tuberculous joints, which are not uncommon. John's

disease is frequently met with; cases occurring in animals from all districts, excepting Ireland, supplying the Salford market. The affected animals appear obvious screws, but it is difficult to differentiate them from tuberculous subjects. These cases are invariably dealt with under the powers of the Public Health Act. I find that animals so affected are usually deficient in muscle, and at the same time when one handles the flank they give one a surprise as to the amount of adipose tissue. This is borne out on post-mortem, as many of these animals kill with a fair amount of fat on an otherwise very plain carcase.

Actinomycosis of the udder is probably not common. When it occurs it is very like a typical case of tuberculosis of the udder, and perhaps the lesion is not so rare as is imagined. Parasitic conditions, *e.g.*, echinococcus cysts in the lungs, are very misleading from a clinical point of view, and are great teachers of the limits of one's powers of diagnosis.

The coenurus cerebri occurs in the brain of cattle, and this also tends to check any sense of security in diagnosis and feeling of confidence which one may have gained after having several cases of tuberculosis of the brain and meninges.

Fluke in sheep causing emaciation and dropsy with looseness of the wool undoubtedly calls for action, and slaughter should be insisted on, with a threat of seizure alive if one's request is not complied with.

While speaking of tuberculosis I mentioned tympany as probably due to tuberculosis of the mediastinal glands. On one occasion I saw this due to actinomycosis of the thoracic portion of the oesophagus; and recently a case due to a non-tuberculous abscess in a mediastinal lymphatic gland.

It appears to me that the Tuberculosis Order is of little use in its powers regarding markets. The Tuberculosis Order made little alteration in the Salford market, the figures being: cows seized in 1911, 71; and in 1912, 41.

In the first place no inspector should need such an order to enable him to deal with emaciated animals; such animals can be dealt with at any time under the Public Health Act.

I should be pleased to have a definition of "emaciated" because it appears to me that the powers that be draw it very hard and fast.

Another objection is the allowing to the owner the option of removing the suspects home again, or to any other area for diagnosis or slaughter, as the case may be. Cases do occur where the animal is slaughtered by the owner, and the market inspector is later informed she was sound, and there is friction. I believe many local authorities wish their veterinary inspector to send these cases back, but if they would take advantage of section 20 (7) of the Diseases of Animals Act, which allows a local authority to withhold compensation if, in their opinion, an owner had been guilty of an offence, and, if possible, have animals dealt with in the market area, it would have a deterrent effect on dealers. I have only had two animals removed from my market since the 1st of May, 1913.

Another and serious difficulty with this Order is when a dealer brings a cow with a suspicious udder, and on the veterinary inspector examining this cow, he (the owner) produces a note signed by the local Police Inspector withdrawing restrictions from a cow of the same description. It is not possible to say the note refers to the cow one is examining and suspecting, and a dealer's word is not always to be believed. The Tuberculosis Order has also given rise to a difficulty with Irish cows. Recently I detained an Irish cow with well marked tuberculosis of the udder, and the dealer—a respectable one—informed me he purchased her in an Irish market the previous week, she had passed through three inspections, viz., Irish market

local veterinary surgeon, Irish Board of Agriculture and English Board of Agriculture, and of course he alleged my diagnosis was wrong. However, on post-mortem next day she proved a case of generalised tuberculosis.

I am anxious to know if the present period of detention and veterinary examination at the ports is for the purpose of examining the animals for all scheduled diseases, or only for those thought to be the more contagious.

In conclusion, I may add that market inspection is very interesting, in that it gives opportunities for confirming, or otherwise, one's diagnosis by an immediate post-mortem. On the other hand, one feels rather disappointed if they have a series of wrong diagnoses and slaughter.

Personally, I feel that veterinary inspectors should have power to detain for examination any animal that appears diseased or unwell—these animals to be placed in properly equipped lairs and kept at the local authority's expense until a complete examination and diagnosis can be made.

DISCUSSION.

Mr. LLOYD wished to thank Mr. Whitehead for his paper, which they would all realise was the outcome of practical experience, and consequently of much more value to many than anything he could have got from books. Referring to the compulsory inspection of markets, and the expression of opinion that the veterinary inspector should have power to detain animals, he entirely agreed that this should be so. Mr. Whitehead had deplored the fact that the veterinary inspector had to be appointed as Inspector of Nuisances in order to enable him to inspect meat intended for food. Two years ago he, Mr. Lloyd, took this matter to the Royal College of Veterinary Surgeons and tried to get it in the Bill, but was unsuccessful, but in 1912 the corporation of Sheffield had a Bill before Parliament and, at his instigation, a clause was inserted similar to one in operation in Swansea, which gives the veterinary inspector the same powers under the Public Health Acts as the Medical Officer of Health has in regard to the inspection of meat.

No doubt there was a difficulty, as mentioned, in markets where fat and store stock were dealt with at the same time. He believed the same difficulty arose in Hull, and he was informed that they had now separate markets for fat cattle and store stock.

In speaking of "barrel chest," Mr. Whitehead forgot to mention an important matter in regard to disease of the thorax—that is the habit of turning out of the elbows. The presence of tympany is often indicative of foreign bodies.

Mr. BURDRED sympathised with Mr. Whitehead in regard to the operation of the Tuberculosis Order, with which he had had considerable experience. His difficulty, and probably that of other cattle market inspectors, was that the tuberculous udders examined are in the early stages with only the higher part affected.

In regard to emaciation his difficulty was to persuade local authorities to take on decided cases and pay compensation for them. He took advantage of a clause which says that when an animal is detained the owner can, if he chooses, have the animal slaughtered without waiting for valuation or completion of the diagnosis.

He also wished to refer to the difficulty of examining cows overstocked with milk, and mentioned a cow which he had seen in the morning without noticing anything wrong, and a few hours after the animal had left the market and been milked he found marked induration of one quarter of the udder.

Mr. MATTINSON thought it was lowering for a veterinary inspector to have to be appointed as Inspector of Nuisances before he could inspect; and he hoped the Council move in the matter.

He was interested to hear that John's disease was not noticed in Irish cattle, and although he had seen many cattle of this breed he had never observed the disease in them.

He would have liked to hear more about brain symptoms and their connection with tuberculosis.

Mr. BRIDGE also spoke of the difficulty of inspection of cattle for tuberculosis of the udder whilst the cattle were in the market. He mentioned the case of a cow bought in the market with which he is connected. The purchaser took the cow home in good faith and after milking found one udder much enlarged. This was at first attributed by the farmer to irritation produced by the milk, but the udder remained enlarged and he notified the occurrence to the local authority. The animal was tested with tuberculin and reacted. On being slaughtered all four quarters were absolutely filled with tubercle, though there was no special enlargement of the mammary gland.

Mr. BRITTELBANK thanked Mr. Whitehead for the very practical manner in which he had placed his material before them. Mr. Whitehead had had a vast amount of experience in one of the largest cattle markets in the country, and must have accumulated an enormous amount of material. Speaking from memory he did not remember having seen any paper dealing with this subject, and thought it of sufficient importance to break fresh ground by seeing the difficulties met with by an inspector in inspecting live animals in markets.

He had often visited the market in which Mr. Whitehead was engaged, and could sympathise with him in his work. Salford could be congratulated on having an inspector with a temperament like Mr. Whitehead's.

There are one or two points illustrating the difficulties that a man may meet with in the examination for disease, and one which he had mentioned a good many times in connection with young store stock suffering from parasitic conditions which are fairly common. He recollected, some years ago, in connection with a herd which is kept free from tuberculosis, being informed by the farmer that a lot of young cattle (12 to 18 months old) were extremely emaciated, and two had died. The bodies of these two were disposed of before a post-mortem examination could be made. The animals were out in outlying pastures. When seen, they presented every symptom of tuberculosis; alternatively was the possibility that they had John's disease. There was something like twenty of them, bred from good stock, and they were recruits for the herd which had to be guaranteed free from tubercle, so that the matter was important. He had them brought up, examined them carefully, and in a few cases found evidence of lung mischief. They were tested with tuberculin but without a single reaction. They improved a little on the dry diet given when they were housed, and by a process of diagnosis by exclusion he decided they were suffering from gastric parasitism. They were treated for this with Thymol, and improvement commenced fairly soon. All got perfectly well, and the lung symptoms disappeared during convalescence. They were tested again a few months afterwards and all passed. He mentioned this to show what a man could meet with in country districts and how difficult it was for an inspector to decide in such cases. He had made rectal examinations, but found on the whole that while some might be enthusiastic about it, to diagnose mesenteric and intestinal tuberculosis, he was not quite so keen, and in the majority of cases there is nearly always sufficient evidence elsewhere.

Meningeal tuberculosis had been referred to, and no doubt if careful post mortem examinations were made much more useful evidence would be collected. Personally, when examining cattle he always looked out

for any departure from the normal, no detail being too trivial to be noted. Peculiarities of gait, jerky flexion and extension, particularly of the fore limbs, the way the animal's head is carried, are all valuable pointers in meningeal tuberculosis. He had seen a fair number of cases and confirmed them at post-mortem.

He did not want to criticise the Tuberculosis Order at all. Difficulties will crop up, but it is admitted by the Board of Agriculture that the Order is an experiment.

Emaciation is a matter of some difficulty. He did not see much difficulty in defining emaciation in animals other than milking cattle, but in regard to these there was difference of opinion. Channel Island cattle, for instance, are almost continually in a condition that one might say was emaciation. If the Order is to be simplified, a clause should be inserted that if in the opinion of the inspecting officer the animal is suffering from emaciation his decision should be final. This would add to the efficiency of the Order and would not allow of these disputes and appeals. Much good could be got out of the Order if administered properly, and with sympathy for the farmers.

He would like to lay stress on one point, that is that every market should have a proper inspection lair with every convenience for the examination of animals. Every officer should be able to require the owner to move an animal to such lair for proper inspection. The difficulties at present are so great as to make examination almost valueless. Big markets should be fully equipped, not only with an inspection lair but should also have proper accommodation for making post-mortems, and a laboratory. Veterinary inspection had come to such a pitch that there should be the necessary equipment for it.

Referring to over-stocking, he said that, as carried out in a large number of markets, it was grossly unfair to the purchaser.

Mr. WHITEHEAD, in reply, said he was pleased at the discussion, and replied to the various points mentioned. Referring to the turning out of the elbows in cases of tuberculosis of the chest, he had always looked for this sign, but it was not always present when he expected it to be. His experience of brain symptoms had been in young stock, and in these he found carrying their heads up, or having a stringhalt action. He had not found them in older animals. The cases where he noticed brain symptoms were usually generalised tuberculosis all through the carcass.

He stated that Prof. Delépine drew a connection between the pharyngeal glands and tuberculosis of the brain, and had tried to reduce the condition. He (Mr. Whitehead) had taken a head to him in which it was found.

The question of over-stocking was an important one, and might be discussed again. Cows were found in the market that had not been milked for nearly 24 hours, and it was difficult to differentiate between discomfort and pain.

Mr. LLOYD moved a hearty vote of thanks to Mr. Whitehead.

Mr. TAYLOR had much pleasure in seconding. The paper had been most interesting, and had been valuable because of the remarks it had drawn from other inspectors. To him it was evident that as time goes on further legislation and further powers must be granted to veterinary inspectors of markets and of meat. That will come in due course, and the sooner the better.

Pathological Specimens. Very interesting specimens were exhibited as follows:—Mr. A. M. MUNRO brought forward one of a very interesting character, viz., cloven feet in an ox. He believed that this case had perhaps been recorded in the veterinary press, but he thought it

of sufficient importance to bring before the members who appreciate it.

Mr. BURNDEED mentioned that he had on one occasion seen a curious specimen of a pig with three feet non-cloven, and the other normal.

Mr. RICHMOND (Bury) also submitted an interesting specimen of the larynx of a horse showing well-developed tumour on the epiglottis.

A hearty vote of thanks to the retiring officers brought the meeting to a close.

J. W. BRITTLEBANK, Hon. Sec.

Cruelty to a Mare.

Before the Hull Bench on Tuesday, January 6th, Edward Winn was summoned for cruelty to a mare on the 17th November.

Lieut.-Col. Seaward Longhurst, F.R.C.V.S., of 174, Beverley Road, stated he saw defendant driving his cab on the morning of the 17th November. Noticing the appearance of the mare, he informed P.C. Smith, who accompanied him to the defendant's stable in Charles Street. He (witness) examined the horse, and found it to be lame in both fore limbs, and acutely lame in the near fore-leg. The mare was evidently suffering pain.

Defendant, asked if he had anything to say, said he had been driving for 63 years, 55 years of which had been in Hull.

The Chairman, addressing the defendant, said he had evidently driven the mare so as to cause it great pain.

A fine of 30s., including costs, was imposed.—*Daily Mail* (Hull).

The Docking of Horses.

A meeting convened by the National Equine Defence League was held in Caxton Hall, Westminster, on 12th inst., to call public attention to the Bill to prohibit the docking of horses, which will be introduced into Parliament next Session, and to the necessity of appointing an adequate number of inspectors for ponies in mines.

Mr. R. B. Cunninghame-Graham, who presided, said that it was untrue that long tails increased danger in driving. Docking was a mere matter of fashion, and the operation was most cruel.

Mr. J. Sutcliffe-Hurndall, M.R.C.V.S., described the operation of docking, which caused much pain and suffering. So convinced was he of the useless cruelty of docking that he had for the last 23 years refused to perform the operation.

Mr. W. A. DellaGana, F.R.C.V.S., said that the operation could be carried out painlessly when there was necessity for it. The cruelty arose from the manner in which the mutilation was done by horse dealers, grooms, and others.

Mr. J. Lee Osborn suggested amendments to the Bill to allow the operation to be performed by a skilled operator for sufficient reason, for inserting a maximum penalty, and for making owners of the animal liable as accessories to the offence.

Mr. F. A. Cox (Hon. Sec.) gave instances of cruelties inflicted upon ponies in mines, and had the support of Mr. R. Smillie (President of the Lanarkshire Miners' Union) on a resolution which was passed unanimously, calling on the Home Secretary to appoint a sufficient number of inspectors to ensure the proper treatment of the animals.—*The Times*.

New Arsenical Compounds.

MOUNEYRAT (*Presse Méd.*, 1913, p. 388) has endeavoured to discover arsenical compounds which shall be free from the neurotropic and vaso-dilator effects of salvarsan, and also possess an energetic parasitropic action in spirochaetes and trypanosomes. The desiderata seem to be obtained with two new bodies, which he terms "galyl" and "ludyl," the former being tetraoxy-diphosphaminodiarsenobenzene; the latter, phenyldisulfaminotetraoxydiaminodiarsenobenzene. These are yellow powders, easily soluble in water. Experiments on animals showed that these bodies have a marked parasitocidal action on *Trypanosoma gambiense*, the spirilla of African recurrent fever and the spirillosis of fowls.

Remarkable results were obtained in 220 cases of human syphilis. Galyl and ludyl may be given by intravenous injection in solution in distilled water. The dose is 45 to 60 cg. for a man, 40 to 50 cg. for a woman. Three injections at intervals of eight days are usually sufficient. The injections are usually well tolerated, and no albuminuria or affection of the optic or auditory nerves were noticed. They can also be given by intramuscular injection in an oily suspension containing 20 to 30 cg. of the drug.—*B. M. J.*

The Election of Council R.C.V.S.

The voting papers to "members residing abroad," numbering roughly 400, will be issued early in February, and will bear only the names of those candidates who have been nominated previous to date of issue.

Veterinary Work in British East Africa.

The Colonial Journal for October, 1913 (Vol. 7, Part 2), says:—"The stock industry of British East Africa is paramount, and receives a great amount of official attention; indeed, it is claimed that no other country in the world has so readily grasped the necessity for veterinary investigation and control. The laboratory is performing operations on a large scale."

THE H. & A. S. AND THE INTERNATIONAL CONGRESS.

At the annual general meeting of members of the Highland and Agricultural Society held on Wednesday 7th inst., in the Society's premises, George IV. Bridge, Edinburgh, the Earl of Dalkeith in the chair:

Dr. Shirra Gibb moved that a donation of £25 be given towards the organising fund of the Tenth International Veterinary Congress to be held in London in July this year.

Mr. Scott Plummer seconded, and this was agreed to.

A constable who arrested the prisoner was the complaining witness. "Your honour," began the policeman, "how would ye like to be called an Irish goat?"

The magistrate smiled a little and observed that the case could hardly be settled on such procedure. "Besides," he added, "I am not Irish."

"Suppose he called ye a German goat?"

"The same objection lies. I am not German."

"Well, then, suppose he called ye the goat that ye are?"

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

INDIA OFFICE, Jan. 9.

The following appointments have been made in India.—

QUARTERMASTER-GENERAL'S BRANCH.

To be a Staff Veterinary Officer, and Personal Assistant to the Director-General, Army Remount Department:—

Capt. E. S. Gillett, A.V.C., vice Maj. W. F. Shore, A.V.C. Dated Nov. 20, 1913.

Personal.

Mr. T. R. JARVIE, M.R.C.V.S., of Jackson Street, Gateshead, accompanied by an employe, was on the point of driving his motor car across Cowen's Crossing, High Blaydon, on Saturday, 10th inst., when one of Messrs. Priestman's locomotives, leaving the North Eastern Railway Company's siding, came up and wrecked the car. Mr. Jarvie was brought home by Mr. Dixon, of Blaydon, in his motor car. Mr. Jarvie's right leg is crushed and fractured under the knee. He is progressing as well as can be expected and there is no sign of any complication.

The late Sir GEORGE BARHAM, of Wadhurst, Sussex the founder and for many years managing director of the Dairy Snpply Co., left estate valued at £259,222.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

Communications for the Editor, to be addressed 20 Fulham Road, London, S.W.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1333.

JANUARY 24, 1914.

Vol. XXVI.

HONORARY ASSOCIATES.

Some time ago the Council decided to elect a number of new Honorary and Foreign Associates on the occasion of the International Veterinary Congress. Following the procedure ordained by the bye-laws, a selection has been made, and a dozen names are now suspended in the Council Chamber for election in April. One is that of Sir Thomas Elliott, and no English layman better deserves the compliment from our profession. The others are those of American and Continental authorities in veterinary science.

So far as it goes, the list is well chosen, but some of the names in it should have been singled out for the honour before—such men as Jensen and Ostertag, for instance, surely ought to have been amongst our Honorary Associates years ago. And the list might very well have been longer.

For a whole generation the Honorary Association of the R.C.V.S. has been very sparingly bestowed. Of our 56 Honorary Associates, fully 35 were elected in 1880. Four more date from 1883, and one of those elected since—Sir Christopher Nixon—resides upon our own shores. We therefore have only 16 foreign veterinary authorities among our Honorary Associates who have been elected within the last thirty years. In face of these figures, the proposed eleven additions certainly seem rather few. We have no wish to see the honour become a cheap one, and perhaps it may have been awarded rather too freely in 1880—but since then we have been going to the other extreme.

HORSE v. MOTOR.

In veterinary addresses we very frequently find allusions to the displacement of horseflesh by motors; but we do not often meet with any very careful examination of the question, nor any just estimate of how rapidly that displacement is progressing to-day, as compared with the beginning of the century. An analysis of the present headway of the motor against the horse, and of the horse's prospects of still holding his own in the classes of work for which he has not yet been displaced, could form the basis of an interesting address; and, if taken up, it may lead to conclusions not altogether pessimistic.

UNCOMMON RENAL CONDITIONS IN CALVES.

In the examination of carcasses of veal the umbilicus, joints and kidneys should receive special attention.

Whilst examining a large amount of veal I came across two conditions of the kidney about which little has been written.

FIBROPLASTIC NEPHRITIS.

This name was given to the condition by Kitt, but it is erroneous, as nephritis is absent. The condition is practically only met with in calves and both kidneys are as a rule affected, the lesions being in the form of disseminated white patches on the surface.

Sometimes there are depressions on the surface of the kidney over the region of the lesions; at other times the kidney is atrophied. One may also meet a hypertrophied kidney with no patches visible to the naked eye, but on microscopical examination it is found to be affected with fibroplastic nephritis.

On section the white spots are wedge shaped, with the base of the wedge towards the cortex. This shape gave rise to the belief that the cause was embolism, and accordingly the term embolic multiple nephritis arose. Microscopic examination of a section shows an imperfect cellular fibrous tissue which displaces and invades the surrounding structures. A few leucocytes may be present.

The cause of this condition is obscure; it has been stated to be of microbic origin, but this requires proof. Some hold that it is caused by the excretion of toxic substances through the kidneys and that those toxic substances arise from existing intestinal lesions. The view that it is the result of incomplete development is held by some observers. Another view is that the condition is caused by high feeding. In nearly every case seen by me the carcase has been well nourished and fit for food.

One must be careful not to confuse this condition with tuberculosis.

MELANOSIS.

The majority of the calves found by me to have melanotic kidneys were from three to six weeks old, in good health and condition, and the pigment as a rule is confined to the kidneys. Brown and black pigment is observed. The kidneys are usually of normal size and consistency and the pigment is found in the cortical portion, the pelvis being normal.

On microscopical examination no pigment is usually found in the malpighian corpuscles, but it

appears to be confined to the convoluted tubes. The cell elements undergo fatty degeneration, partial necrosis, and epithelial hypertrophy. The condition in adults is rare.

Some observers state that the pigment in the kidneys is the same as that of the bile.

W. J. YOUNG, F.R.C.V.S., D.V.S.M.

AN UNUSUAL DISLOCATION.

Subject. A bay hunter gelding, four years old, the property of, and ridden by J. B. Jarmay, Esq., of Bulkeley Hall, Malpas.

History. In a run with the Cheshire hounds at Rushton, Tarporley, on the 14th, the gelding jumped quite a small fence. Mr. Jarmay felt her give way, and on dismounting (the horse did not fall at once) he saw a bone protruding from each hind leg.

I arrived within five minutes of the accident; the horse had then been shot. Both metatarsal bones were protruding about four inches through the skin on the anterior aspect of the fetlock; I found the capsular and lateral ligaments of both fetlocks ruptured. On the off leg the suspensory was divided about its lower third, the extensor and flexor tendons being intact and having slipped to the off side. On the near leg the extensor tendon was ruptured, the suspensory and flexors being intact.

T. O. RICHARDSON, F.R.C.V.S.

Tarporley, Jan. 14.

ABSTRACTS FROM FOREIGN JOURNALS

A BOVINE DISEASE CAUSED BY THE BACILLUS NECROPHORUS.

M. Balog, a Hungarian veterinary surgeon, describes (*Allatorvosi Lapok*) a disease which he has observed for some years in cattle, and which he has hitherto regarded as an atypical form of bovine malignant catarrhal fever. In most cases the disease appears suddenly, with acute symptoms and high fever. The eyelids are swollen, the conjunctivæ are injected, and the visible mucous membranes are bright red. Loss of appetite and complete apathy are also observed, with, in many cases, necrotic ulcers of the mucous membrane of the mouth. The disease appears sporadically, and is not transmissible. In its further course, symptoms indicating gastric and intestinal inflammation are observed. The prognosis is unfavourable in most cases, the patients die if they are not slaughtered.

Post-mortem, in addition to the appearances mentioned above, necrotic patches which reach up to the size of a thaler (coin) are found in the rumen, omasum, and abomasum, and also upon the mucous membrane of the small intestine.

The *bacillus necrophorus* was demonstrated in the ulcers at the Institute of Pathological Anatomy

of the Veterinary High School of Budapest. Probably the bacillus is not the immediate cause of the disease, but only a secondary infection attacking an organism weakened by other causes. In the cases of necrobacillosis hitherto described (Miessner, Bartels, Hasenkamp) broncho-pneumonia occurs. In Balog's cases, alterations of the lungs were not demonstrable.—(*Berliner Tier. Woch.*)

FIBROLYSIN IN STRANGLES.

Michael Schmidt reports (*Allatorvosi Lapok*) that he has used Merck's fibrolysin for a variety of conditions. Amongst these are the connective tissue proliferations and swellings which not infrequently persist in strangles after the opening of the abscesses. The result in these cases was striking, for after the subcutaneous injection of the contents of a phial (= 11.5 c.c. of fibrolysin) the swelling retrogressed in a few days without leaving a trace behind. In addition, Schmidt has used fibrolysin with good results in different cutaneous thickenings, sclerosis and elephantiasis, inflammations of the tendons and tendon-sheaths, and other conditions. Its use is very simple and convenient, for it can be introduced subcutaneously as well as intravenously or intramuscularly. It causes no undesirable by-effects or complications.—(*Berliner Tier. Woch.*)

OPTIC NEURITIS IN HORSES.

A. Mayer and Erich Hieronymi record (*Monatshefte für Prakt. Tierheilkunde*) the two following cases.

A thoroughbred stallion, seven years old, which some time before had recovered from a severe bilateral pleuro-pneumonia, suddenly refused food and showed paralysis of the penis.

The next day, the horse was blind in both eyes. Externally, no lesions of disease of any kind were perceptible upon the eyes. Ophthalmoscopic examination showed that the optic papilla had disappeared, and that in its place was a snow-white body, dimly lustrous, appearing like little lumps of snow balled together. The authors also compare the appearance to that of rice grains. The alterations were similar in both eyes, and the power of vision had disappeared in both.

Treatment consisted in the subcutaneous injection of $\frac{1}{2}$ grain of arecolin hydrobromide at intervals of two days, and the simultaneous instillation of atropine-cocaine solution (1 part each to 100 parts of water) into the conjunctival sac. The penis was rubbed daily with camphor ointment.

On the seventh day the paralysis of the penis had disappeared. The new formations in both eyes lessened, became detached, and floated in the vitreous humour. The blindness remained complete. The diagnosis was "neuritis optica exudativa bilateralis."

The second case was an eight-year-old gelding, which, according to the history, suddenly became blind without any preceding illness. Clinical examination revealed no symptoms of either external or internal disease. No abnormality in the eyes could be demonstrated by external examination. Ophthalmic examination showed, in place of the optic papilla, gleaming blood-red spots of

irregular form, between which lay white marrow like looking bodies the size of grains of rice. The condition was alike in both eyes, and the horse was completely blind.

Post-mortem examination revealed the rice-like and fungous eminences which had been shown by the ophthalmoscope. They were extremely flaccid, and were not united to the tissues supporting them. Microscopically they appeared amorphous, and disintegrated in preparation. Histological examination of longitudinal and transverse sections of the optic nerve showed accumulations of round cells in the nerve sheaths and nerve bundles—the picture of a neuritis optica.—*Münchener Tier. Woch.*

W. R. C.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, AUG. 3—8, 1914.

A meeting of the Organising Committee was held at 10 Red Lion Square, W.C., on Friday, January 9th, 1914. Present: Sir John M'Fadyean in the Chair, Messrs. Almond, Banham, Barrett, Dr. Bradley, Messrs. Bullock, Carter, Clarke, Crabb, Garnett, Hobday, Lawson, Prof. Mettam, Col. J. Moore, Mr. Price, Major-Genl. Pringle, Messrs. Share-Jones, Slocock, Maj.-Genl. F. Smith, Sir S. Stockman, Mr. Sumner, Major A. G. Todd, Messrs. Trigger, Willett, and Prof. Wooldridge.

Minutes. The minutes of the previous meeting were read and confirmed.

Absentees.—Apologies for absence were received from the following: Messrs. J. Dunstan, H. J. Dawes, F. W. Emery, Prof. Gofton, Messrs. Henderson, J. W. McIntosh, T. E. Jones, J. S. Lloyd, G. P. Male, J. Malcolm, A. I. MacCallum, C. Rutherford, W. A. Taylor, C. Stephenson, P. Wilson, S. Villar.

Invitations to Congress. The HON. SEC. reported that, in addition to the invitations sent out by the Foreign and Colonial Officers, there still remained the question of the invitations to be sent to Veterinary Schools which were not Government Schools, to Municipalities, to Agricultural Societies, etc.

The HON. TREASURER stated that he had already written to several Breed Societies and others, informing them that they would in due time be invited to send delegates to the Congress.

The PRESIDENT: I think we should not propose to cast our net so wide as appears to have been done by another Society whose papers I have before me. We have to remember that every delegate appointed will involve us really in expense. The will get the full privileges of membership for the sum of £1, but that will not really cover the expenses. I do not therefore think we should address invitations to every town or county council in the Kingdom, but I certainly think we ought to issue invitations to schools as suggested, and to all the important agricultural associations and breed societies. We should like to have them send delegates.

On the proposition of Mr. Share-Jones, seconded by Mr. Slocock, it was resolved that invitations be issued, signed by the President and Secretary, to all schools not likely to have been invited by the Foreign or Colonial Offices, and to all important agricultural and breeding societies in Great Britain.

REPORTERS.

The following report of the Sub-Committee for the selection of reporters was received and adopted:—

A meeting of the Committee appointed to select

reporters was held at 10, Red Lion Square, W.C., on Friday, January 9th, 1914. Present: Sir John M'Fadyean in the Chair, Messrs. Banham, Carter, Garnett, Prof. Mettam, Mr. Price, Maj.-Genl. F. Smith, Sir S. Stockman, Major A. G. Todd, Prof. Wooldridge.

Minutes. The minutes of the previous meeting were read and confirmed.

Reporters. The HON. SEC. reported the result of correspondence with the reporters invited, most of whom had accepted. In the cases of refusal he had written to others on the list recommended by the National Committees, and the list was now as follows:—

GENERAL MEETINGS.

1.

Official Opening.

2.

Foot-and-Mouth Disease.

REPORTERS [Those marked * have not yet replied]:—

Herr Geheimer Regierungsrat Dr. Nevermann, Berlin.
M. E. Leclainche, Inspecteur General Chef des Services Sanitaires, au Ministère de l'Agriculture, Paris.

* Dr. Mohler, United States Department of Agriculture.
M. le Docteur Remmelts, Chief Inspector of the Veterinary Service, The Hague.

Herr Prof. E. Hess, in der Fakultät der Veterinarmedizin, Universität, Bern.

Prof. A. E. Mettam, Principal, Royal Veterinary College of Ireland.

Dr. Josef Rudovsky, Landes Veterinäreferent, Brunn,

3.

Tuberculosis.

Herr Prof. Dr. Eber, Direktor des Veterinar Instituts, eipzig.

M. le Prof. Vallée, Directeur de l'Ecole Veterinaire, Alfort.

Prof. Sir John M'Fadyean, Principal, Royal Veterinary College, London.

M. G. Regner, Veterinary Department, Ministry of Agriculture, Stockholm.

M. le Prof. de Jong, University, Leiden.

4.

Epizootic Abortion.

Herr Regierungsrat Prof. Dr. Zwick, Kaiserliche Gesundheitsamte, Berlin.

M. le Prof. Moussu, l'Ecole Vétérinaire, Alfort.

Herr Sanitätstierarzt Sven Wall, Öffentlicher Schlachthof, Stockholm.

Sir Stewart Stockman, Chief Veterinary Officer, Board of Agriculture, London.

5.

Public Control of the Distribution and Sale of Milk in the Interests of Public Health.

Dr. A. D. Melvin, Chief of the Bureau of Animal Industry, Washington.

Herr Geheimer Regierungsrat Prof. Dr. von Ostertag, Direktor der Veterinarabteilung des Kaiserlichen Gesundheitsamtes, Berlin.

M. S. P. Nystedt, Erste Stadtierarzt, Stockholm.

Mr. J. W. Brittlebank, D.V.S.M., M.R.C.V.S., Public Health Department, Manchester.

6.

Closing Meeting.

SECTION 1. [Veterinary Science in Relation to Public Health].

(1) Meat Poisoning—Its Pathogenesis and the Measures necessary to guard against it.

Herr Prof. Bongert, Tierärztlichen Hochschule, Berlin.
Schlachthofdirektor Dr. Hans Messner, Karlsbad.

* Dr. Gillaume. Directeur de l'Abattoir de la Ville de Nice.

(2) General Principles to be Observed in the Inspection of Carcasses and Organs of Tuberculous Animals with a view to Determine their safety as Articles of Human Food.

M. le Dr. Stubbe, Inspecteur Veterinaire General au Ministère de l'Interieur, Brussels.

M. Cesari, Vétérinaire Sanitaire de la Seine, Paris.

Herr Obertierarzt Dr. Nieberle, Hamburg.

*Herr Sanitätsveterinar Hy. Hansson, Stockholm.

(3) Disinfection of Waggon.

M. le Prof. Dr. E. Bidart, à la Faculté de Médecine Vétérinaire, Université, Buenos Aires.

Herr Regierarzngnat Dr. Titze, Kaiserliche Gesundheitsamte, Berlin.

M. Rabieaux, Inspecteur General des Services Sanitaires aux Ministère de l'Agriculture, Paris.

*Prof. Meloni, Naples.

SECTION II. Pathology and Bacteriology.

(1) Johne's Disease.

M. le Dr. Olaf Bang, Copenhagen.

Herr Prof. Dr. Miessner, Tierärztliche Hochschule, Hannover.

Mr. A. L. Sheather, B.Sc., M.R.C.V.S., Royal Veterinary College, London.

(2) Bovine Piroplasmiasis [European].

Herr Prof. Dr. Knuth, Abteilungvarstcher im Hygienischen Institut, Tierärztliche Hochschule, Berlin.

M. le Prof. S. von Ratz, l'Ecole Vétérinaire Supérieure, Budapest.

Mr. W. G. Wragg, M.R.C.V.S., Laboratory of the Board of Agriculture, London.

(3) Ultra-visible Viruses.

Dr. K. F. Meyer, University of California, U.S.A.

M. le Prof. Panisset, l'Ecole Vétérinaire, Lyon.

*Herr Dozent Dr. Pfeiler, Leiter der Abteilung für Tierhygiene am Kaiser Wilhelm Institut, Bromberg.

(4) Distemper—Etiology and Vaccination.

Herr Prof. Dr. S. Sigismund Markowski, Tierärztliche Hochschule, Lemberg.

M. Carré, Chef de Laboratoire au Laboratoire des Recherches du Ministère de l'Agriculture, l'Ecole Vétérinaire, Alfort.

SECTION III. Epizootiology.

(1) Anthrax.

Dr. W. H. Dalrymple, Louisiana State University, U.S.A.

Herr Dr. Aladar Lukacs, Laboratorium für Schutzimpfstoffe, Budapest.

Herr Rektor und Prof. Dr. J. Szpilman, Tierärztliche Hochschule, Lemberg.

Major Holmes, Imperial Bacteriologist, Muktesar, India.

(2) Swine Fever.

Dr. Marion Dorset, U.S.A. Department of Agriculture, Washington.

Herr Holrat Rektor und Prof. Dr. Hutyrá, Tierärztliche Hochschule, Budapest.

*Herr Bezerkstierarzt Dr. R. Frauenberger, Friestadt, Austria.

*Herr Dr. Glässer, Repetitor an der Tierärztlichen Hochschule, Hannover.

(3) Glanders.

M. M. de Roo, Inspecteur Vétérinaire Principal, au Ministère de l'Agriculture, Brussels.

M. Drouin, Vétérinaire Directeur de la Cavalerie de la Cie Generale des Voitures de Paris.

Herr Prof. Dr. J. Schnürer, Tierärztliche Hochschule Vienna.

Mr. J. R. Jackson, M.R.C.V.S., Board of Agriculture, London.

Herr Prof. Dr. Peter, Landestierarzt, Hannover.

(4) Sarcoptic Mange of the Horse.

M. le Vétérinaire Principal A. Barrier, Paris.

Col. Butler, War Office, London.

Herr Landesveterinäreferent Theophil Halaki, Czernowitz, Austria.

SECTION IV. Veterinary Medicine and Surgery.

(1) Anæsthesia.

M. le Prof. Hendricks, l'Ecole Vétérinaire, Brussels.

Dr. L. A. Merrill, Chicago, U.S.A.

Herr Prof. Vennerholm, Tierärztliche Hochschule, Stockholm.

Prof. G. H. Wooldridge, Royal Veterinary College, London.

(2) Laminitis.

M. le Prof. Liénaux, l'Ecole Vétérinaire, Brussels.

M. le Vétérinaire Principal Joly, du 9ième Corps l'Armée, Tours.

Prof. James Macqueen, Royal Veterinary College London.

(3) Surgical Treatment of Roaring.

Herr Prof. Dr. Eberlein, Tierärztliche Hochschule, Berlin.

Dr. W. L. Williams, Cornell University, U.S.A.

M. le Prof. Dr. Fontaine, l'Ecole de Cavalerie, Saumur.

Mr. F. T. G. Hobday, F.R.S.E., F.R.C.V.S., London.

(4) The Use of Drugs in the Treatment of Disease caused by Nematode Worms.

M. le Prof. Van den Eckhout, l'Ecole Vétérinaire, Brussels.

M. le Prof. Railliet, l'Ecole Vétérinaire, Alfort.

Prof. J. F. Craig, M.A., M.R.C.V.S., Royal Veterinary College of Ireland, Dublin.

M. le Prof. Perroncito, R. Università di Torino, Instituto di Parassitologie, Turin.

SECTION V. Tropical Diseases.

(1) Diseases Transmitted by Ticks; their Classification, Treatment, and Prevention.

* Dr. D. E. Salmon, Washington, U.S.A.

M. le Prof. J. Lignières, Faculté de Médecine Vétérinaire de l'université, Directeur de l'Institut National de Bacteriologie, Ministère de l'Agriculture, Buenos Aires.

Sir A. Theiler, K.C.M.G., Director of Veterinary Research, Transvaal.

Mr. C. E. Gray, M.R.C.V.S., Principal Veterinary Surgeon, Transvaal.

*Dr. Paulo Parreiras Horta, Directoria, Service de Veterinaria, Rio de Janeiro.

(4) Diseases Transmitted by Winged Insects; their Classification, Treatment, and Prevention.

M. Cazalbou, Vétérinaire en 1ère au 70ième d'Artillerie, Rennes.

Mr. R. E. Montgomery, M.R.C.V.S., Veterinary Bacteriologist, Department of Agriculture, Nairobi, British East Africa.

*Dr. L. O. M. Howard, Bureau of Entomology, Department of Agriculture, Washington, U.S.A.

*Dr. Pinto Guedes, Rio de Janeiro.

*Dr. Christino Cruz Filho, Rio de Janeiro.

Prof. A. Lanfranchi, Directeur Institute de Pathologie Vétérinaire, Parma, Italie.

[The list was adopted].

The Hon. Sec. asked for authority to print the list of reporters, and to issue it to the National Committees, together with a programme of the Congress. Agreed.

Lantern. It was resolved that arrangements should be made for the provision of a lantern for the purpose of illustrating the papers where necessary.

The Hon. Sec. reported that he had received applications from certain gentlemen for permission to read papers unofficially on subjects other than those in the programme, and on the motion of Mr. Lawson, seconded by Mr. Barrett, it was unanimously decided that no additions be made to the programme as already arranged.

Excursions. The question of the arrangement of excursions, etc., was considered, and it was ultimately resolved that the matter be left in the hands of the Hall Committee, with the addition of Prof. Hobday.

Honorary Treasurer's Report. Mr. GARNETT reported that at the previous meeting he had stated that the sum of £1,060 was at that time in the bank. As a result of the appeals issued by Sir John M'Fadyean to the profession, and by himself to members of the Royal Agricultural Society of England, whose names had been kindly furnished by Mr. McRow, and to Agricultural Societies, he had very greatly increased the number of individual members of the profession who had subscribed, and he had also received considerable sums from the other sources mentioned.

The number of members of the profession who had subscribed had more than doubled in the three months, and with the addition of Officers of the A.V.S. and A.V.C., there was now about 700 on the list of subscribers. The total amount paid or promised up to date was about £3,800, of which there was actually paid into the bank £2,700, including, of course, the £500 of the reserve fund. He still wished to continue his appeal for there yet remained the sum of £200 to be collected before the amount of the minimum of £4,000 was reached. He wished to thank *The Veterinary Record* for the notice which they had kindly inserted free of charge in their columns, which had been a very great help to him.

Membership Tickets, Entertainments, etc. The question of the printing of the membership tickets, the arrangements of entertainments, etc., was considered and after discussion it was resolved to refer these matters, and all other matters of detail, to an Executive Committee to be composed of the members of the Hall Committee, with added members, as follows: The Chairman, the Hon. Secretary, the Hon. Treasurer, Messrs. Banham, Barrett, Crabb, Hobday, Jackson, Col. Moore, Messrs. MacCormack, Price, Willett, and Prof. Wooldridge, with power to add to their number.

Hall. The following report of the meeting of the Sub-Committee on the selection of a hall for the Congress was received and adopted:—

A meeting of the Hall Committee was held at 10, Red Lion Square, W.C., on Friday, January 9th, 1914. Present: Sir John M'Fadyean in the Chair, Messrs. Banham, Clarke, Garnett, Price, Sir S. Stockman, Mr. Willett, Prof. Wooldridge.

Minutes. The minutes of the previous meeting were read and confirmed.

Hall. The Hon. Sec. reported that arrangements had been completed for the hire of the Central Buildings, Westminster, at a rental which was considered satisfactory.

Insurance. It was resolved that the Hon. Secretary and Treasurer be authorised to take out an insurance policy against all risks arising from the temporary tenancy of the hall.

A discussion arose as to the allotting of space for exhibits, and the selection of firms who were to be allowed to exhibit. On the proposition of Prof. Wooldridge it was resolved that the allotting of space for

exhibits, and the selection of firms, be left in the hands of the Executive Committee.

Assistant Secretaries. The Hon. Sec. reported that, as authorised, he had made the following arrangements for Assistant Secretaries:—

Maj. Todd to take charge of arrangements in connection with the A.V.S. and the A.V.C.

Prof. Wooldridge to take charge of travelling arrangements.

Mr. J. R. Jackson to take charge of hotel accommodation.

Dr. J. McL. McCall to take charge of organising the Ladies' Committee.

Delegates. The Hon. Sec. submitted the following list of countries which had so far promised to send delegates to the Congress:—

The Commonwealth of Australia, Bulgaria, Barbadoes, Belgium, Canada, China, Denmark, Holland, India, Luxemburg, Leeward Islands, New Zealand, South Africa, Western Australia.

It was also resolved that Mr. F. Bullock be appointed paid Assistant Secretary, with authority to obtain any necessary clerical assistance.

CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH].

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, January 8th. Prof. G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book:—Messrs. J. Willett, G. Gordon, M. G. Byerley, J. B. Buxton, Wm. Roots, W. R. Davis, Capt. G. Rees-Mogg, N. Almond, Prof. E. B. Reynolds, F. G. Samson, S. H. Slocock, H. D. Jones, J. W. McIntosh, R. A. Philp, S. L. Slocock, J. A. Gosling, H. J. Parkin, W. R. Clarke, G. Dunlop Martin, W. Perryman, R. Eaglesham, L. Auchterlonie, E. Lionel Stroud, D. H. Wood, J. F. Macdonald, Wm. Willis, H. King, and Hugh A. MacCormack, Hon. Secretary.

Visitors: Messrs. L. Wooldridge, H. H. Curson, R. Finch, P. S. Sparling, H. B. Williams, H. S. Cockburn, and W. H. Wortley.

On the motion of Mr. N. Almond, seconded by Mr. Samson, the minutes of the last meeting were taken as read and signed.

Correspondence. The Hon. Secretary said he had received a letter from Mr. Henry Gray enclosing a circular letter with respect to the Wm. Hunting Memorial Fund, as follows:—

23 Upper Phillimore Place,
London, W.

THE HUNTING FUND.

Dear Sir,

You are probably aware that a movement has been set on foot to raise a fund in recognition of the life and work of the late Mr. William Hunting; and we think you will agree that no man, since our profession was first formed, ever better deserved its gratitude.

The Committee which has been formed to give effect to the proposal has been purposely made large and representative, so as to embrace all sections of the profession. It consists of (1) The Council and Board of Examiners of the R.C.V.S. (2) The Principals and Professors of all English, Scotch, Irish, and Colonial Veterinary Schools. (3) The Presidents and Secretaries of all existing Veterinary Societies throughout the British Empire. (4) All officers of the Army Veterinary Service at home and abroad. (5) All officers of the Indian Civil Veterinary Department, and (6) All veterinary officers of departments of agriculture and sanitation in the British Empire. A small acting

sub-committee of thirteen members (Prof. J. Macqueen, Chairman; Mr. Henry Gray, Hon. Sec. and Treas.; Messrs. Hugh Begg, W. Roger Clarke, J. Emerton, E. Wallis Hoare, R. C. Irving, Hugh A. MacCormack, Sir John M'Fadyean, Capt. G. Rees-Mogg, General F. Smith, Sir Stewart Stockman, and Prof. G. H. Woodbridge) has been appointed to arrange details, while the main decisions regarding the disposal of the Fund will be made by the General Committee.

From the above statement of the constitution of the General Committee you will see that you are yourself one of its members. Whether or not you are able to attend its meetings, we trust you will do all in your power to further the progress of the Fund. It is hoped that every member of the committee will subscribe to the Fund individually, and use his personal influence to induce others to do likewise.

Subscriptions will be welcomed either from societies or individuals, either within or without the profession. They should be sent to Mr. Henry Gray, 23 Upper Phillimore Place, London, W., who asks that cheques should be made payable to the "Hunting Fund," and crossed "The London City and Midland Bank, Kensington Branch."

All suggestions from donors regarding the disposition of the Fund will be welcomed and duly considered.

We are, dear Sir, yours faithfully,

J. MACQUEEN, Chairman.

H. GRAY, Hon. Sec. and Treasurer.

It was moved by Mr. Samson, seconded by Mr. J. Willett, and carried unanimously: "That the Society instruct the Council to make a grant of 20 guineas to the Wm. Hunting Memorial Fund."

The HON. SECRETARY announced the receipt of a letter from the Secretary of the Royal Sanitary Institute asking the Society to send delegates to the Congress to be held at Blackpool, July 6th to 11th.

On the suggestion of the President it was agreed to postpone the appointment of delegates till March or April.

MORBID SPECIMENS.

Mr. W. PERRYMAN said he had a specimen which was not strictly a morbid one, unless it were called a necrosed piece of wood. A client had taken a mare to drive in the country, and during the night she was put in a meadow. After three or four days she was found with a punctured shoulder, believed to have been caused by a gore from a bullock, and was sent back to town by train. On examination he found a punctured wound about 2½ inches long. He inserted his finger and felt a hard substance some three inches higher up, a second wound was made when some of the pieces of wood now exhibited were withdrawn. Feeling that there was still others left, he had recourse to another cut higher up and found another piece of wood 8½ inches long, which had been driven right up to the top of the withers. This, he thought, could not have been done by the mere force of the impact, but must have been caused by the muscular movement of the limb. To his surprise the deeper muscles of the shoulder were not lacerated. The piece of wood was under the panniculus muscle. He thought the piece of wood had been gradually worked up to the top. He believed he had secured good drainage, the wound assumed a healthy appearance and the lameness passed off, but the wound did not close. The first cut had been made on the 6th August, and on the 28th he saw that the wound beneath was quite smooth. He had noticed more than once that where two muscles played over each other, instead of getting granulating surfaces they became smooth, with no tendency to heal. He therefore decided to make a common wound of the three openings by opening from top to bottom. This was done, the wound

being 11 inches long. The surgical wound granulated and healed perfectly. At one time, by the muscular retraction the granulating surface was some three inches wide. This gradually drew together and illustrated how well wounds close when there has been no destruction of tissue. On seeing the mare some ten days ago he observed that the scar was no thicker than the rim of a penny; in fact one would not easily see it without clipping the hair off.

He mentioned the case because it illustrated the importance of making a thorough search of punctured wounds, and not to rely always upon the report of the case given by the attendant. The owner had been perfectly convinced that the animal had been gored.

Mr. N. ALMOND asked whether the foreign body could be felt from the outside?

Mr. PERRYMAN said there was a good deal of swelling at first but no indication of a foreign body.

Mr. SAMSON asked if any explanation could be offered as to how it happened.

Mr. PERRYMAN replied in the negative.

The PRESIDENT was very interested in Mr. Perryman's case and expressed the opinion that that was a kind of case which was much more frequently met with in hunting districts than in towns or the neighbourhood of towns. He had met with similar cases himself in which pieces of stake had been found as deep as a foot from the surface, in such positions as the axilla, and the way in which those large portions left behind had passed the large vessels of the axilla and the brachial plexus had been little short of marvellous. In one case the end of a stake which had been left behind was a foot in length and he had to insert his arm up the wound in the axilla almost to his elbow before reaching it. The only reason it was suspected then, apart from the extreme lameness of the animal, was the fact that the stake had been pulled out by the rider, and on being closely examined a fractured end was exposed, proving pretty clearly that something had been left behind.

Mr. S. H. SLOCOCK said one had often heard it stated by elderly nervous men that it was no good to suture a wound, and that it healed quite as quickly without. To some extent he thought that was correct, but he had not so far lost his nerve as to want to believe in that entirely yet. In the case mentioned by Mr. Perryman it seemed that a wonderfully good healing process was obtained and the fact that the scar was so small had been emphasised.

The PRESIDENT pointed out that a more common example of the advantages that might result from not suturing deeper wounds were to be found in the case of operations of the larynx, where the external wound was never sutured, and it held up beautifully; it was most difficult to find a scar although at one time there might be a breach of several inches right across from lip to lip.

Mr. S. H. SLOCOCK observed that in that case there was no tension of the skin as there would be on the shoulder.

The PRESIDENT suggested that in Mr. Perryman's case also, the wound being in the vertical direction, there would be little or no tension. Had it been the other way there would have been considerable tension and a big scar left. With incisions for poll evil and fistulous withers if they were made crosswise one got a big cicatrix; if they were made longitudinally there was very little scar.

ELECTION OF FELLOWS.

Messrs. H. H. WORROW, M.R.C.V.S., 156 High Street, Shadwell, E.; and J. R. HAYHURST, M.R.C.V.S., Metropolitan Cattle Market, Islington, N., were unanimously elected Fellows of the Society.

TRAUMATIC MALADIES OF THE FOOT OF THE HORSE.

By W. R. DAVIS, M.R.C.V.S.

Some, it is said, have greatness thrust upon them. Whatever importance attaches to the position in which I now find myself has neither been desired nor sought by me. I am, in fact, here by order of your President, who rang me up on the 'phone, wished me a Happy Xmas, and did his best to prevent the fulfilment of his wish by saying that the member who was to have read a paper to-night was unable to do so, and requesting me to take his place. I make these preliminary remarks in order to disarm hostile criticism, and to claim your indulgence for the manifest deficiencies that you will observe in these notes.

Treads of the Coronet are common, and affect mostly the hind feet. In the fore feet they usually result from over-reaching, and frequently, especially in hunters, a bit of skin may be partly cut off. Don't stitch or bandage; snip it off, and apply Friars balsam or tincture of aloes and myrrh, good old-fashioned vulneraries.

In the hind feet a common result of a tread is a slough of a piece of skin. Injury to the extensor tendon is observed too, but I have never seen the joint opened, although one may have a deep cavity after removal of the slough. It is to be remembered that the skin is here very thick. In very cold weather, and especially where salt is used on tram lines to melt snow, every tread seemed to result in necrosis of skin and great lameness.

The nearer the horn the seat of injury is the more severe is the lameness and the more intractable the case, as here suppuration may take place in the laminae and spread, detaching horn, burrowing along the coronet, and giving great trouble. A pad of cotton wool soaked with solution of perchloride of mercury 1:1000 and kept on with a bandage is, I think, good treatment.

A word about the bandage. Not a filthy bit of old Newmarket bandage, but a piece of new calico; one can buy 12 yards for 3s., and it pays to have it.

Wounds about the Coronet are not uncommon. I will describe two that I have treated recently. A four-year-old Shire horse at grass got fast in barbed wire. A neighbour freed the animal by cutting the wire, but could not remove the embedded piece. On my arrival I found a piece of wire lying deep in the foot and extending from the cleft of the frog to the anterior part of the coronet.

I managed to get it out with a pair of pincers, and having syringed out the wound with chinosol, and put on wool and bandage to stop bleeding, the horse was taken home on a float.

The patient did no good, and was destroyed after about ten days treatment. A post-mortem showed that the joint was extensively opened, the navicular bone abraded, and its ligaments torn. The wound was treated by syringing with chinosol solution, and insertion of gauze soaked in the solution.

In the second case a horsekeeper in putting up the bed touched a mare with a fork, she kicked out, and the prong entering at the heel went within the lateral cartilage and came out at the coronet. The fork being withdrawn, the mare went down and rolled about as though she had colic. I found her sweating and standing on three legs. With a fine-pointed syringe I washed out the track of the fork with perchloride of mercury solution 1:500, until I found it issuing from the opposite orifice. A wad of wool soaked in perchloride and bandaged on completed the treatment. The patient was better in a week.

A farmer once brought me a horse's hoof with a piece of fractured pedal bone in it, and asked me if I would treat the case. The horse had got his foot fast in the cogs of the surface wheel of a thrashing mill, and in his struggles had torn the hoof off. I advised the owner to go home and shoot the patient. I have often wondered whether I ought not to have attempted treatment.

Fracture of the navicular bone may, of course, occur in the diseased bone without great violence being inflicted, but I have seen a fracture of an apparently healthy navicular take place through a horse starting a heavy load. A wagon laden with two tons of coal pulled up at an inn, the carter went into the house, and when he came out a short time after and started the horse, it went violently lame on a hind leg and was led home. Though it was evident that the lameness was due to serious injury in the foot, nothing could be found. Prof. Macqueen was called in consultation; he made a prolonged search but could not determine the exact nature of the injury. The horse finally died in the slings, and on post-mortem a fractured navicular was found. A few days before death a bulging took place in the hollow of the heel and at the coronet, this, on being incised, discharged much sanguinolent pus, the foot was full of this pus.

Fractures within the hoof are, of course, extremely difficult to diagnose.

The prognosis of injuries to the pastern and coronet due to wheels of vehicles, to blows, kicks, etc., needs to be guarded, as after an apparent recovery an exostosis may develop followed by permanent lameness, requiring neurectomy to relieve it.

Does sprain of the structures within the hoof occur? I am inclined to think so. I have often had cases of lameness which I felt certain were connected with the foot, and which responded to baths and poultices.

Should we include laminitis as an affection of the foot due to traumatism? Cadiot says distinctly that we should. He considers that concussion is the cause, and that feeding, chills, etc., merely favour the development of the malady. I am quite convinced that he is wrong. (Of course, we know that a horse very lame on one foot may get inflammation in the opposite foot, but in this case all the secretory membrane is affected, and not the laminae particularly.)

I remember once being called to a foal whose dam broke out of her box, got on to the road and galloped for nearly four miles, her four days old foal following her all the way. No laminitis developed. The disease is, I think, always due to poisons absorbed from internal organs—from the intestines usually; in parturient laminitis from the uterus.

I remember reading a statement made by that keen observer, Prof. Pritchard, to the effect that flour given to the horse frequently induced laminitis. A truer remark was never made. Ground wheat, bran containing much flour, pea and bean meal, maize (to horses unaccustomed to it) all these will give rise to laminitis. Meal and water given to hunters will do it.

Stiff-sickness—really laminitis of cattle, frequently observed in South Africa, has been proved by feeding experiments to be caused by the animals eating a plant, *Crotalaria Burkiana*. Whatever the cause is, the treatment comprises three principal indications:—1. An oleaginous purge: 2. Casting the patient: 3. Hot poultices on the feet. Where the case is a severe one, I almost think that casting is the most necessary indication to fulfil, yet I have searched all the veterinary literature at my disposal and have not found it insisted on; and indeed only mentioned casually by two writers.

A hint here as to how to put a horse down in a stall (every farm has not the roomy, airy loose box often prescribed in text books and essays). Make a good long

bed. Put a rope on the near fore pastern, pass it under the belly and over the back to the near side again, and into the stall on the left. Put another rope on the near hind pastern, pass its end in front of the off hind leg and into the stall on the right. Loose the horse and pull the head well round to the off side; pull both ropes and down he slithers, and so long as the rope on the near foreleg is kept taut it is impossible for the horse to get up if he wants to. If he has laminitis he is glad to lie for a few hours.

A nail bag serves well to put the poultice in, but a piece of stout sacking does well enough: they are best fastened on with a hamestrap. The poultice ought to be soaked with hot water several times a day.

After the horse has lain six hours it may be allowed to get up and have water and hay given to it: in four hours it should be cast again. This casting should continue for three days if the animal refuses to go down itself. It should then receive a little exercise without shoes and have a pair of plain, thin heeled shoes put on to exercise in. I suppose that acute laminitis is still sometimes treated by the application of bar shoes and forced exercise. I tried the plan once, and I can only say that I formed the opinion which I still hold—that it is a stupid and brutal method.

Parturient laminitis differs little from the disease when caused by feeding. It often follows retention of pieces of foetal membranes, and in my opinion is frequently associated with washing out the uterus after removal of retained membranes. I think it is best to put in an antiseptic pessary, or inject a few ounces of carbolic oil when one has removed the membranes from a mare. Parturient laminitis is not uncommon in cows.

Gathered nail. One of the commonest traumatic affections of the horse's foot results from the animal picking up nails, screws, bolts, etc. These objects usually glide off the bars and sole, and pierce the softer horn at the junction of sole and frog. The gravity of the wound inflicted depends, apart from depth penetrated, on its point of entry. If this is situated in the posterior or anterior third, little danger is to be feared usually. In the middle third, however, a deep wound may be attended with serious consequences and may, indeed, result in the destruction of the animal, for here the offending body, after traversing the velvety tissue and plantar cushion, as it would do in other positions in the frog, may pierce the plantar aponeurosis, open the navicular bursa, and even wound the navicular bone. A case is recorded where the os corona was fractured by a nail that had penetrated the frog.

Let me utter a word of warning. When searching the foot for causes of lameness, never forget to have the frog cut down. I have known a very good blacksmith miss a buried nail in the frog.

The most essential thing to do here is to find the track of the nail and wash it out with a reliable antiseptic. Frog horn is difficult to search, the deeper layers cede before the farrier's knife, and the horse resents its pressure. I use a very sharp sage knife to thin the deeper layers, and sometimes make a cruciform incision with a Syme's abscess knife over the black spot that shows where the nail has been. Whatever difficulties there are, one should not rest until the track is explored and washed out if one wants to be safe.

I have here what I may call a needle probe. It is an ordinary large hypodermic needle with the point cut off and a blob of solder put on. It is usually not difficult to introduce this into the track, and then a reliable strong antiseptic can be injected. The needle-probe fits hypodermic syringes, and may be obtained from Messrs. C. H. Huish & Co. You don't want half a pint, a few drams suffice, then push into the track a few strands of gauze wet with the antiseptic, put a pad of cotton wool wet with the antiseptic on top, and a

piece of sack overall. If there is great lameness, a hot poultice may be applied instead of the wool for the first day or two. A shoe may be tacked on in these cases and then the wool dressing is easily kept in place. Wounds from nails, etc., in the posterior third of the frog involve damage to the velvety tissue and to the plantar cushion, and where suppuration takes place there may be swelling and discharge in the hollow of the heel. If the antiseptic can be syringed right through, such cases do not usually cause much trouble. Towards the point of the frog the foreign body may injure the pedal bone, and if there is suppuration a slough of the superficial part of the bone may occur, and it may be necessary to lay bare the parts, remove the piece of bone, and curette the surface; usually, however, the application of tincture of iodine suffices.

In the middle zone of the frog the foreign body is much more liable to do serious damage, yet if one intervenes early enough, and is able to prevent infection by syringing out the track and by the application of antiseptic dressings, a cure may be looked for, even if the navicular bursa is penetrated and synovia is escaping from the wound. I have seen such a case myself more than once.

When the wound has become infected, as usually happens after continual poulticing, and suppuration has taken place, the horn for some distance will be under-run and should be in part removed, the nail track will now be patent, and ought to be flushed out and plugged with gauze soaked in antiseptic, and a pad of wool put on. I think that antiseptic foot baths are useful here. If the plantar aponeurosis is involved, tincture of iodine on gauze may be introduced; this may also be tried in suppuration of the navicular bursa. The disastrous effects of continued poulticing are seen when the pus burrows along the tunic of the plantar cushion and bursts at the heel and along the tendons, and ulcerates through the skin at the cannon.

Where there is continued suppuration and great lameness the classical operation is to remove horny sole, frog, and bars, then divide transversely the plantar cushion at its middle, remove the anterior part, divide transversely the plantar aponeurosis and remove its anterior also, curette the semilunar crest, and the inferior surface of the navicular bone, put on iodoform and dry wool. The operation may succeed in the case of heavy horses used at a walk. I have never performed the operation except on the dead animal. I do not think it is often done in this country.

Someone has imagined a drill to open the nail track. I think that I have seen horses to drill whose hind frogs, when they have gathered a nail, would present difficulties.

Injuries Received in Shoeing. That is called a bind, in which the soft horn is penetrated and the nail presses on the laminae, giving rise to temporary lameness. A few poultices usually suffice to put this right.

In the case of a drawn nail, the nail wounds the laminae, but the smith recognises the wrong direction and withdraws the offending body, leaves the nail hole empty, and in the majority of cases there are no ill effects. Where complications do occur, their course is similar to that followed in the case of *pricks*, where the nail remains in position. However, the last case of tetanus I saw was due to a drawn nail, and had been treated by the farmer with poultices until the disappearance of the lameness.

In pricks in shoeing suppuration usually takes place, and the horse goes lame in a few days, or perhaps not for a week or more. It is a curious fact that a horse may go quite suddenly violently lame, and on examining the foot a good deal of suppuration may be found with considerable separation of horn, and it is apt to be asserted—in cruelty prosecutions for instance—that such an animal must have been long lame.

For the most part pricks are found affecting the quarters where the wall is thin. The pus usually burrows towards the heel, and may go up to the coronet there. Often, too, it finds its way along the velvety tissue of the sole, separating the horn for a considerable distance.

The diagnosis of pricks is quite easy at times—I have seen discharge issuing at the clinch, at other times it may be hesitating. After the pus is evacuated, syringe with an antiseptic, apply wool dressings after having put a few strands of antiseptic gauze in the hole.

Should the foot be poulticed after the evacuation of the pus in an ordinary pricked foot? Although I occasionally use a poultice for the first day in such a case if the lameness is great, my own opinion is that they are unnecessary, and that their continued use should be condemned, in fact wherever the secretory membrane of the foot is exposed, nothing should be applied but a surgical dressing.

If suppuration is considerable, with detachment of horn, great swelling of the coronet, the parts being bathed in pus, I fix the wad of wool on the solar surface by tying stout cord round the hoof, putting a nick with a rasp on the inside and outside lower aspect of the wall to prevent the cord slipping, leave the coronet bare and soak it three times a day with antiseptics, leave the bed down and keep it clean.

The general statement is sometimes made that whenever horn is separated by pus, such horn ought to be removed. Perhaps that would be a useful point to discuss in relation to what has just been stated with regard to the treatment of pricks.

Wounds from the clip of a pulled off shoe may pierce to the pedal bone, and if infection takes place, which mostly occurs if the injury is only treated by poulticing, necrosis of a portion of the bone and of the velvety tissue and of the laminae may result, and pus may make its way to the coronet in front. The treatment is much the same as for pricks. If the pus reaches the coronet, the point of the syringe should be inserted into the lower orifice, and the antiseptic should be injected until it appears at the coronet.

Corns. Traumatism acting on the velvety tissue included between bar and wall, and also on the laminae there, mostly on the inside of a fore foot, give rise to inflammation of the keratogenous membrane, which may result in hæmorrhagic staining of the horn (dry corn), to serous exudation (moist corn), or to suppuration when infection has taken place.

What are the causes of corn? Are they entirely the result of shoeing? As they are never seen in unshod feet, I think it may be accepted that corns do result from the necessity of having horses shod. Shoes left on too long, short shoes as in hunters, cutting away the bars and sole at the posterior part of the foot and thus determining the approach of bar and wall, ablation of the frog at each shoeing, or prevention of its functioning by thick heeled shoes and the consequent wiring in of the heels, are all factors that lead to corn. Compression of the velvety tissue between the retrossal process and the sole is a cause, according to Bouley. Is it possible that the "heel bones" discovered at one of our seats of learning may be agents in the etiology of corns?

Why are corns found on the inside of the foot? I cannot say, any more than I can explain why splints are found on the inside of the cannon, or why canker when it affects the wall is mostly observed on the inside heel, and is always most severe there.

Treatment. A horse lame from a non-suppurating corn should after removal of the shoe have a hot foot bath and stand in a hot poultice—always with bed down for a day or so, and then have a threequarter shoe put on and the wall of the affected heel well rasped down. Do not, however, dig out the seat of corn if non-

suppurating. If suppuration has taken place give a hot foot bath, inject out the track of the pus with antiseptic, and push up a few strands of gauze soaked in strong antiseptic into the track and apply wool soaked in the antiseptic, and a bag over all.

If pus has appeared at the coronet wash out with the antiseptic from below till the solution appears at the coronet, put in gauze, apply wool below, but do not put on sacking, and wash the coronet several times daily with antiseptic.

Prevention of Corns. According to Cadiot, the Omnibus Company of Paris almost eliminated corns from their 15,500 horses by shoeing with what was practically a stout tip, thus developing a big, hard frog and strong wide heels. The perpetuation of corn is, in my opinion, due to the smith searching for corns every time the animal is shod.

This ends my notes. I am quite aware how bald a statement it is of a very wide and interesting subject. To quote Tyndall: "With more time or greater knowledge what has been here said might have been better said, while worthy matters, here omitted, might have received fit expression." However, if I have provided a theme for discussion my function is accomplished: there are many around me who are well fitted to fill the lacunae.

DISCUSSION.

Mr. SAMSON, after expressing his thanks to the author for the time and trouble he had taken to prepare the paper, asked why he preferred oil. In the first place it was slow; secondly, it was nasty to give and use. Personally he would prefer to pop down a good strong physic ball. In such acute cases in the earlier stage he had always found it a good plan to scarify round the coronet with a half-inch or three-quarter-inch wide lancet, get a water can with a long spout and water the coronet with hot water. It would flood the stable and make the place look as if the horse would bleed to death, but he would walk better next morning. In the case of the suppuration of the horn under the poll he did not gather whether Mr. Davis followed it up and cut it away. Personally he invariably followed it to the end. If that were not done the horse might go sound for a time, but suppuration would take place again later on.

Some mention had been made of heel bones. At one meeting he had had a good look at specimens of such, and had come to the conclusion that they were only the good old-fashioned sidebones of different shapes. They were not always of the same shape any more than bunions were in the human subject.

A mare which he had ridden for thirteen years broke her pelvis. She was never touched; she had never even lain down. The late Mr. Hunting and Mr. Wragg had seen her, and Mr. Hunting thought it was a bad case, and suggested that as it would make a very good post-mortem she had better be killed. As he believed he could not replace her for a couple of hundred pounds he did not follow that suggestion, but rested her for six months—and hunted her for years afterwards. He had never done anything to her. Much to his regret he had had to kill horses with broken pelvis on several occasions.

In regard to tips for corns, the mare had very bad ones, but she never had any before being shod. It reminded him of his own shoemaker, whom he regarded not so much as a shoemaker as a corn-maker. He had never known a horse have corns till shod. His own mare was at length kept in a stable in which there were hard blue stones without any straw, in order that her feet might be hardened gradually, and finally he got her to a very short tip and hunted her for seven years in tips and then drove her for a time in tips, free from corns.

Mr. J. WILLETT thought the paper was just the kind of thing that was wanted. It was of course open to a lot of criticism. He did not know whether Mr. Davis agreed with poulticing in treads of the hoof.

Mr. DAVIS said he certainly did.

Mr. J. WILLETT, continuing, said that the lameness which followed a tread might not show itself for a week. There might be a bruising of the coronet which did not go to suppuration. The horse might gradually get sound and resolution follow after resting without any treatment. With regard to laminitis, he had been interested in the fact that Mr. Davis cast the patient. He had never tried that himself, but had always put them in slings, though if they lay down of their own accord he let them, provided they did not get bed sores. If a horse with bad laminitis was allowed to lie he had a tendency to get bed sores very quickly.

Mr. DAVIS pointed out that he had mentioned the horse only lay a few hours.

Mr. WILLETT said the difficulty in that case was to get the animal up. After a horse had been worked so much as to get out of condition there was frequently a footsoreness which bordered on laminitis. He could not put it down to anything but an inflammation of the foot, which he considered was due to concussion. He would ask the author whether he favoured hot or cold poultices in the treatment of laminitis?

Mr. DAVIS said he had stated that he preferred hot poultices.

Mr. WILLETT, continuing, thought that the tendency in cases of gathered nail to leave the shoe off and poultice the foot in a bag was bad treatment, and added considerably to the pain suffered by the animal. If the foot were well cut out it was much the better plan to put the shoe on again afterwards. No doubt it had been Mr. Davis's experience, as well as his own, to find in regard to prick that sometimes the lameness had not appeared for quite a fortnight. He had found the better mode of examination of a horse for prick was to tap the clinches round with a hammer. If one tapped the horn the animal would draw his foot up sharply, but if one got a man to hold the other leg up and tap the clinches round, the horse would give at the knee as soon as the blow was given. He had found that of great assistance in locating the damage, and saved a great deal of time.

He was not quite in agreement with Mr. Samson and Mr. Davis that corns were always caused by shoeing, as he had seen at least two unshod colts with corns. Also, a corn would very often start with a bruised heel caused by a picked-up stone. But no doubt the usual way in which corns were formed was by defective shoeing. Mr. Davis had remarked that he considered corns were caused by the continual searching for them, but the corn which might be called a chronic bruising of the heel, required easing down each time. There was often a hard horn growing right over, and until one cut right down one did not come to it. Also, it was his experience that it was very often necessary to cut down the sole and the bar and the wall away in order to get the horse sound. There was very much pain caused by the corn growing down between the sole and the outside wall, and one could not get down to the bottom to give relief without cutting down lower in the wall and the sole. If one found a corn running down the wall, the best thing was to have the horn rasped right away, even to the coronet, until one got to the white horn underneath, and then gradually pare down right round the corn and leave it bulging up, and then at the last pare down the top of the corn. Of course it took about three months for the horn to grow down to its normal state, but his experience was that there would be very little trouble with corns on that foot afterwards. Tips, in the lighter horse, he thought were of great benefit when corns were present, but he did not see how they were

to be used with heavier animals whose heels were weak, in fact no definite rule could be laid down.

Capt. REES-MOGG thought that foot trouble caused about 80 per cent. of cases of lameness. He had seen bleeding from the jugular vein tried in one case of acute laminitis and great success to follow. Whether the bleeding had anything to do with the success or not he did not know, but it seemed reasonable to suppose that it had. In a case where there was pus in the foot, he had found that antiseptics syringed into the cavity very often did not go so far as one wanted them to go, and the only way to get the pus away was, after making a sufficiently large opening at the bottom, to soak the foot in a bucket of hot water to which some antiseptic had been added, lift up the sound leg, and then there was some chance of the pressure on the lame foot forcing the pus out. He asked whether a three-quarter bar shoe was not preferable to a three-quarter shoe in a case of corns.

Mr. J. W. MCINTOSH said those in practice in the East of London had a good deal to do with injuries of the nature described by the author; for instance, treads of the coronet were very common, more frequently seen in the hind limbs, but now and again in the fore limbs. Many of these injuries result in the destruction of a considerable amount of tissue, and serious and even fatal results sometimes follow. He had still faith in poultices—provided it was not over done—and he nearly always applied them in such cases; they had a soothing effect, hastened the detachment of dead tissue and cleansed the wound.

With regard to the case of fracture of the navicular, which Mr. Davis had mentioned, he was inclined to think that that had taken place some time previously, but displacement had not occurred until the extra effort of starting the load was required.

Laminitis, he thought, was not very common in London practice—at least that was his experience. Out of a stud of nine hundred horses he had no more than two or three cases in six years. He could not account for the small percentage. It was certainly not from want of hard work. His method of treatment was somewhat different from that of Mr. Davis. He believed in cold poultices—the colder the better—and he was opposed to the giving of a purgative as he experienced bad results from its use—the risk of translating the inflammatory process from the structures of the feet to the bowels was a very undesirable one. He considered a purgative unnecessary, a laxative diet was all that was needed, and if with this, the weight of the body be taken off the limbs, either by slinging or casting, the best results may be hoped for. After the acute stage is over, put on good broad webbed shoes, blister round the coronets and run the animal rough for a period.

With reference to "Canker" he was not perhaps as energetic as some veterinary surgeons, and unless the animal was a very valuable one, he preferred to pass it on as quickly as possible.

Gathered nails was a great source of worry and loss to London horse owners. Many of them producing permanent and even fatal results. Get them well cut out and cleansed either by tubing, poulticing or the injection of antiseptics, or a combination of all; unfortunately, however, there are cases which seem to defy the resources of the pharmacopœia and end fatally.

Pricks, on the other hand, were not quite so serious, although sometimes troublesome, and invariably—if discovered in time—ended in recovery under the usual methods of treatment.

As to corns, he was not much troubled with this complaint, but when he did get them, he believed in having them well pared out and either tubed, poulticed or dressed antiseptically. Careful shoeing was essential to the well being of the horse, and the less the foot is

mutilated by the blacksmith the better. A good deal of harm resulted from cutting away the bars, thus weakening the weight bearing part of the foot and exposing it to such injuries as corns and other maladies.

Mr. W. PERRYMAN thought the expression "tread at the coronet" was very misleading. Very few of the wounds at the coronet were truly caused by a big tread. The majority were really scratches with bacterial infection, and the size of necrosed tissue which sloughed out had nothing to do with the force of the original injury. He would ask Mr. Davis whether he thought it was due to the force of the injury as the word "tread" implied, or to bacterial infection, which was very rapid in some cases. In laminitis, he always thought the proper course of treatment was to lower the wall. The inflamed area was the laminae of the foot. The wall of the foot was always more prominent than the sole, but by lowering the crust or wall the weight of the body was distributed over the whole of the plantar surface. With respect to the fracture of the navicular, he was very doubtful whether it occurred in the way mentioned by Mr. Davis. He thought while the driver was having his drink the wheel of another vehicle had probably gone over the foot, and left no outward injury. In connection with the diagnosis of pricks, he always carried a little hammer with him and found it most useful in examining the horse's foot. It was far better than a heavy hammer. When examining a foot with a hammer he thought it best to hold the limb himself and so be able to appreciate if the animal flinched. With a small hammer the foot could be more carefully tested and the offending nail more easily located.

Mr. H. D. JONES believed that laminitis was sometimes the result of fatigue. When an animal came in with fever in the feet and a high temperature Mr. Davis recommended purging at once, he thought a sedative is often indicated. He thought linseed meal was preferable to bran for poulticing, the latter often going sour and giving off an objectionable smell. As to injuries of the coronet, he endorsed what Mr. Perryman had said, that they were sometimes the result of scratches and not treads. They were often found on the outside of the coronet where real treads could not occur. In cases of suppuration all round the coronet, he had found the best treatment was to thin the horn. His experience of puncture of the navicular bursa was that the results were very unsatisfactory. If the animal were cured there was generally permanent lameness.

Mr. WOOD agreed with Mr. Davis in thinking that the best treatment in the case of laminitis was to have the horse cast as soon as possible, in order to get the weight off the feet. It was easily done by fixing up the near fore leg and pulling the horse's head round to the off-side, but a little room was required for that. In the case of a horse standing in a stall, one should fix a thin rope on to the halter, pull the head round to the off-shoulder, pass the rope underneath the girth over the back and loop it underneath the rope again, take a similar turn round the flank, and then stand behind him and pull.

Prof. REYNOLDS agreed with Mr. Davis that fractures of the navicular bone might occur from sudden strain or concussion. In support of this view he mentioned a case coming within his own experience. A cart horse employed in drawing hay from a field had to take at a rush a short steep incline, about ten to fifteen yards long, from the field on to the hard road. On getting on to the road he was pulled up to catch his wind, and it was then noticed he was holding up one hind foot, apparently suffering some considerable pain, but on making him move he showed no great lameness, and was able to draw the load home on the flat road, a distance of about two miles. The next morning he was very lame, and continued so. He was treated by his

owner with poultices, fomentations, and oils. He did not see the horse for six weeks. There was then great swelling and suppuration. The toe was turned up off the ground, the limb resting on the hollow of the heel. From the history of the case, and from the symptoms shown, he thought that possibly it was fracture of the navicular, and it proved to be so. He felt convinced the fracture was caused by the severe tension on the foot when the horse was drawing the load out of the field. He joined Mr. Sampson in asking Mr. Davis why he preferred an oleaginous purgative in laminitis. It was somewhat slow in action. Mr. McIntosh had said he did not think it advisable to give aloes, as it sometimes set up too irritant effects on the intestine. He (Prof. Reynolds) suggested the use of arecoline or eserine, these being quicker than oil and safer than aloes. He thought it a good plan, after carrying out ordinary treatment for two or three days, to get the shoes on the horse and give him exercise; the great thing was to encourage circulation in the foot.

Mr. BYERLEY thoroughly agreed with the author as to the use of poultices, but he had not said that they should always be medicated. To apply an unmedicated poultice was a most reprehensible practice, because conditions were set up which favoured the development of septic organisms. Medicated poultices afforded very great relief and were open to no objection whatever. As to whether they should be cold or hot depended entirely upon the condition which was being treated. In laminitis the cold poultice was preferable. Mr. Davis said that in his practice he never applied any protection to openings at the top of the foot. While it was bad practice to apply tight bandages or applications to any part of the foot because they prevented proper drainage, still it was absolutely necessary that all parts should be protected; and it was wrong to allow any open wound to be constantly running the risk of being contaminated by stable refuse.

The injection of antiseptics into wounds of the foot was always advisable, but he had not had good results where he had forced gauze or other packings into the cavities, because they prevented free drainage from the wounds and frequently added to the pain of the animal. He entirely endorsed what Mr. Davis said with regard to the digging out process for corns which was frequently carried on by farriers. They were not entirely to blame, because they generally acted under superior instructions. Digging out the corns not only robbed the foot of support but converted a simple corn into what was constantly giving rise afterwards to suppurative condition. Protection of the sensitive parts was removed and septic organisms gained entrance to the foot.

The PRESIDENT asked the members whether they would prefer that the discussion should stand adjourned owing to the lateness of the hour.

On the motion of Mr. N. Almond, seconded by Mr. Eaglesham, it was agreed that the discussion should stand adjourned to the next meeting.

It was moved by the Hon. Sec., seconded by Prof. Reynolds, and agreed to, that a vote of thanks be given to Mr. Perryman for his interesting specimen.

HUGH A. MACCORMACK Hon. Sec.

R. D. S. Spring Show.

The Royal Dublin Society spring show will be held on Tuesday, April 14th and three following days.

Entries close at single fees on February 23rd, and at double fees on February 26th. The last date for polo ponies to be entered is March 13th, and entries for the jumping competitions close on April 2nd. Applications for entry forms should be made to the Agricultural Superintendent, Leinster House, Dublin.

Royal College of Veterinary Surgeons.

A special meeting of Council was held at the College 10 Red Lion Square, W.C., on Tuesday, January 20th. There were present: Mr. Hobday, Sir John M'Fadyean, Messrs. Mulvey, Price, Maj.-General Pringle, Prof. Shave, Mr. Slocock, Sir S. Stockman, and Mr. Fred Bullock, Secretary.

Chairman. In the absence of the President, Mr. T. S. Price was appointed to the chair.

Absentees. Apologies for absence were received from the President, Messrs. Barrett, Dunstan, Garnett, Lloyd, Dr. J. McL. McCall, Messrs. McKinna, Mason, Prof. Mettam, Messrs. Packman and Shipley.

Minutes. The minutes of the previous special meeting were read and confirmed.

Bye-laws. On the motion of Sir John M'Fadyean, it was resolved that the following additions to the bye-laws, passed at a special meeting of Council held on Jan. 9th, 1914, be confirmed:—

62 (a) *Exemption.* (i) Students who have obtained a Degree in Arts, Science, or Medicine of any University in the United Kingdom, or the Diploma of Licentiate of the Royal Colleges of Surgeons and of the Royal Colleges of Physicians, and who at the respective examinations for such Degree or Diploma, have passed in Chemistry, and also in Biology, Zoology, or Botany, are exempted from attendance at the first year's Course of Lectures and from the examina-

tion at the end of that year, provided that each student so exempted shall be examined in the whole subject of Anatomy in the Class B Examination.

(ii) Students claiming exemption under this Bye-law must submit to the Secretary of the Royal College of Veterinary Surgeons, not less than three months before they intend to present themselves for the B Examination, satisfactory evidence that they are entitled to the exemption.

(iii) Candidates possessing similar qualifications granted by Colonial or Foreign licensing bodies, shall submit their Certificates to the Examination Committee, who shall report to the Council on the eligibility of the applicant for exemption or otherwise.

This concluded the business.

"Not Confirmed."

A cow died on the home farm at Stoke Edith, the residence of Mr. Paul Foley, and Mr. Foley's veterinary surgeon, on an analysis of the blood, certified it to be a case of anthrax. The matter was reported to the police authorities, whose veterinary surgeon gave a similar certificate. The cow was then burned, and all the formalities gone through. About a week afterwards a letter was received from the Board of Agriculture stating that the case was not anthrax, but giving no information as to the possible cause of death. The owner has sent in a bill to the County Council to meet the expenditure incurred. No blame is attached to the police. The Board of Agriculture have been asked to explain the delay.—*The Hereford Times.*

NOTE.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

BONE FORMATION FOLLOWING TRAUMATISM.

The following abstract is from a paper on Traumatic Intramuscular Ossification (usually known as myositis ossificans traumatica), by John Morley, Ch.M., F.R.C.S., in *The British Medical Journal* of December 6th. It has interest inasmuch as it carries the work of Macewen on bone formation a step further, and from the fact that plates of bone, for which no sufficient explanation has been given, have been found in the gluteal muscles and in the muscles on the external aspect of the thigh in the horse.

The condition to be described follows the infliction of a single severe contusion, and must be distinguished clearly from two other types of intramuscular ossification—namely, (1) myositis ossificans progressiva, which starts early in life, usually in the muscles of the back, and ultimately causes death from respiratory failure; and (2) ossification into tendons, the result of slight, repeated mechanical irritation, such as "rider's bone."

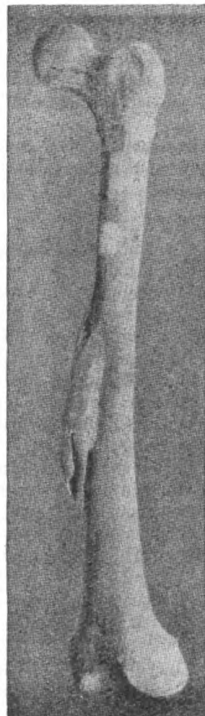

After a severe, blunt, subcutaneous injury to a limb, usually the thigh or upper arm, a mass of bone develops in the contused muscles. Various theories have been entertained as to the origin and nature of this bony growth, a full discussion of which is given by Lapointe in a recent paper.

Briefly, the theories fall into three main groups, namely:

1. Tumour formation.
2. Metaplastic inflammation of muscular connective tissue.
3. Mechanical.

The truth of the mechanical view of its causation is suggested by certain facts concerning the incidence of the condition. Of a series of 233 cases collected from the records of the German Army in ten years by Schultz, all but three were situated in the quadriceps or brachialis anticus. The patients are usually young adult or adolescent males. The type of injury is always a severe subcutaneous contusion, and it is remarkable, on looking through the literature, how many cases are due to a kick on the front of the thigh or a blow with a fist on the front of the upper arm. Now in both these situations we have a broad, smooth, convex area of bone, covered by periosteum that is loosely attached and readily stripped off owing to the absence of tendinous insertions. This point has impressed many observers, and has given rise to the view that the lacerated muscle fibres may retract, carrying torn fragments of periosteum away from the bone, and that these fragments act as grafts producing bone. Others hold that as a result of trauma the cells of the deep layer of the periosteum are stimulated to proliferate. These views must be abandoned, however, since they are based on an erroneous conception of the function of the periosteum. The work of Macewen has shown conclusively that the periosteum does not act as a bone producer, but as a limiting membrane to the growth of osteoblasts. Working on dogs, he showed that the so-called osteogenetic layer of the periosteum is really a subperiosteal layer of areolar tissue which normally contains osteoblasts in the growing bone only; that in healthy adult bone this subperiosteal areolar space contains few osteoblasts or none, so that transplanted periosteum does not produce bone; and that subperiosteal deposits of bone produced by irritation are due to the pouring out of osteoblasts into the subperiosteal space from the deeper parts of the bone via the Haversian canals.

In the light of these facts, and of the investigations I now record, I consider the pathology of traumatic intramuscular ossification to be as follows: A severe blunt injury at once subcutaneously strips off and destroys the periosteum, and crushes the muscles in contact with the

essentially similar to the condition that occurs in man may be produced by curetting off the periosteum from the front of a rabbit's femur, and crushing the adjacent muscles. Ossification occurs by the migration of osteoblasts into the crushed muscles and blood clots lying in contact with the denuded bone. That devitalization of the muscles by crushing is an essential factor is shown by the fact that when the periosteum is removed, and the muscles are not crushed, little, if any, exuberant growth of bone occurs. This fact agrees with the observations of Macewen.

HISTOLOGY.

For microscopical examination, a bar of bone, some 3 cm. long, removed at the first operation, was chosen. It was cylindrical in shape, with a diameter of 0.5 cm. at its widest part, and was almost completely surrounded by fibres of the muscles, in which it was growing parallel to their long axis. This piece of bone was decalcified, and transverse and longitudinal sections cut and stained with hæmatoxylin and eosin.

Transverse sections show a definite formation of spongy bone arranged in irregular trabeculae, with large vascular medullary spaces between, in which a few multi-nucleated cells and many oval cells of embryonic connective tissue type are seen. The osseous matrix takes on a definite pink with the eosin. In the centre of the bone is an area of hyaline cartilage, avascular, and merging into bone at its periphery. The cartilage is distinguished from the osseous tissue by the non-staining character of its hyaline matrix, by large cell spaces, and round nuclei, faintly stained with blue. It appears to be undergoing rapid cell division. The periphery of the bony mass is nowhere in immediate contact with muscle fibres, but is surrounded by and merges into a layer of primitive fibrous tissue containing many oval nuclei. It is evident that these embryonic connective tissue cells are actively infiltrating the

bone. Bleeding occurs from the surface of the denuded bone, and, with the blood, osteoblasts in a free and possibly amoeboid condition escape into the pulped muscle tissue and blood, and there produce a growth of bone. As Macewen has shown, healthy muscles left in contact with denuded bone form protective fibrous adhesions from their interstitial connective tissue, and so take on the limiting function of the periosteum. My own investigations show that severely contused muscle tissue mixed with blood, so far from restraining the migration and growth of osteoblasts, provides a very favourable pabulum for them.

EXPERIMENTAL CONFIRMATION

By the kindness of Prof. Boycott I have been able to perform experiments on rabbits in the pathological laboratories of Manchester University. These investigations are not yet complete, and will form the subject of a subsequent communication. It may be stated as a preliminary report, however, that intramuscular ossification

The photograph illustrates:—Old-standing traumatic "myositis ossificans," showing incomplete reabsorption and transformation into dense bone. [Museum specimen.]

muscle and destroying its fibres. Here and there isolated and degenerate muscle fibres are seen surrounded by this tissue, and a little further from the bone it is seen to be invading the muscle substance by infiltration between its fibres. There is a general increase of the intramuscular fibrous tissue.

Longitudinal sections show particularly well this process of infiltration and destruction of muscle tissue by these indifferent connective tissue cells.

Interpretation.

The first point of interest is the nature and origin of the cells that are infiltrating the muscle fibres and paving the way for the growth of true bone. Do they originate in the intramuscular connective tissue or in bone? A minute examination of a number of these sections under a high power lens convinces me that they are simply osteoblasts in an actively dividing preosseous stage. The outer margin of the definite bony tissue passes by insensible degrees into this embryonic fibrous tissue, which here and there takes on faintly the pink stain seen in the fully developed osseous matrix. Similarly cells can everywhere be seen in every stage of transition between the mature osteoblast and these indifferent connective tissue cells. This conclusion is, of course, supported by the experimental evidence given above.

The section shows further in a striking manner that the cartilage cells are also identical with the osteoblasts, though in a different matrix, for between these again all stages of transition are seen. The importance of this conception of the essential unity of the osteoblast and chondroblast is obvious in connection with our ideas on the growth of bone. There is now a very general feeling of scepticism towards the classical description of ossification in cartilage. Macewen holds that the osteoblast and chondroblast are the same cell in different guise. Wingate Todd, as the result of extensive histological investigations, concludes that "osteoblasts are fibroblasts or connective tissue cells which have undergone certain characteristic modifications, and may or may not have passed through a chondroblast stage." With these authorities I am in entire agreement. The explanation of the presence of cartilage here is not so simple. The cartilage plainly originated from bone, and would probably have been transformed in course of time into bony tissue. I am inclined to think that the presence of cartilage in the centre of the bar of bone is to be explained by its lower vascularity, since we know that an essential difference between bone and cartilage is that the former is vascular, the latter avascular.

The main purpose of this paper is to advocate excision with grafting of a stout layer of deep fascia or aponeurosis on to the denuded bone. As stated above, the result in my own case was a complete success, and has saved the patient at the least many months of incapacity for work.

The Mines Act, 1911—A Prosecution.

A prosecution under the Coal Mines Regulation Act took place at Neath County Police Court, on Friday, Jan. 16th, when the defendants were David William Thomas, colliery manager, Seven Sisters; Daniel Lewis, James Bafton, D. T. Davies, and John Parry, horse-keepers, Seven Sisters. There were three summonses against the manager, and two against each of the other men. Mr. Edward Powell prosecuted for the Home Office, and Mr. Trevor Hunter (instructed by Mr. A. J. Jeffries) defended.

The prosecutions were taken under the third schedule of the New Mines Act, 1911. In the case against Parry, summoned for working five horses in an unfit state, Mr. T. Lloyd Evans, inspector of pit horses under the Home Office, said that on September 15 he visited the colliery,

and there found five horses, for which Parry was responsible, working when unfit. On "Margam" there were five sores, on "Boxer" two, on "Fly" four, and on "Steamer" and "Charlie" one each.

Cross-examined: The horses, apart from the sores, which must have been painful, were in fairly good condition.

There was a second summons against Parry for not keeping a proper record in the horse-keeper's book. This defendant pleaded guilty to.

Called for the defence, Veterinary Surgeon Phillips said that he visited the colliery and examined the horses on the 12th and 16th of last September. It was a common thing for colliery horses to receive minor injuries, he said, and it was better for animals to work than to be idle when the sores were protected.

Cross-examined: The report of the Home Office Inspector was correct, but exaggerated. Witness made his examinations at the colliery stables between the shifts. The statement of the inspector that the sores were old was quite wrong. They were new.

Mr. Hunter, addressing the justices, said it was admitted that there were sores on the horses when the inspector visited the pit, but the defendant was in no way responsible for them, for the veterinary surgeon had clearly stated that the sores were caused on the actual working day.

The Bench intimated that they had decided to convict, and Mr. Hunter said he could not put the cases any higher in connection with Lewis, Bafton, and Davies, similarly summoned, and pleaded guilty.

The summonses against the manager were in respect of a roof of insufficient height, of not exercising proper supervision over the horse-keepers in keeping their books, and of an insufficient supply of water in the workings.

Mr. Hunter said it spoke well for the management of the mine—in which there was a good deal of "squeezing"—that the inspector could only find three places where the roof was too low to meet with the requirements of the Act in regard to "roughing" or "rubbing" of colliery horses. Referring to the insufficient supply of water in the workings, learned counsel said that there was an ample supply of water in the stables, but the management had overlooked the provisions of the Act in respect of the workings. This had, however, now been remedied.

Mr. Hunter pleaded not guilty to the summons charging defendant with not exercising personal supervision over the horse-keepers.

In this case the manager was ordered to pay costs. In respect of the others he was fined 30s. and costs. The other men were fined 25s. and costs each.—*Western Mail*.

"Scrapie" Seventy Years Ago.

A correspondent of *The Scotsman* writes:—Sir Stewart Stockman, in his address at St. Boswells, said that the earliest information about the disease under the name of "scrapie" which he had been able to acquire dated back to 1853. This week, in conversation with an aged Border shepherd, I was told of an outbreak which goes further back than that. Ten years before the date given by the Chief Veterinary Officer of the Board of Agriculture, a farmer from the Scottish side of the Cheviots attended a sale of sheep on a Northumberland farm, and purchased a lot of Cheviot ewes, which were placed among his own stock and given the run of the regular grazings. In a short while all the imported ewes perished from the disease, but not one of the other sheep on the holding was affected by the malady, and it has never appeared on that particular farm since. This is good evidence, surely, as the old herd put it, that "scrapie" is not "smittle."

Bran as Food for Stock.

In the report of an experiment carried out by the East of Scotland Agricultural College, bran was compared with linseed cake in rations of which the other ingredients in each case were Bombay cotton cake, roots, and oat straw. The two lots of cattle made very nearly the same increase in weight, but the advantage, both in cost per cwt. of live weight and in percentage of dead weight, was slightly with the bran. The two lots of beasts sold at almost identical prices, there being no difference in the quality of the beef that could be attributed to the feeding.

The bran was fed dry, the cattle eating it readily out of their troughs. It is said to be more digestible dry than when moistened or scalded and made into a mash, the reason given being that the animal does not masticate the moist food thoroughly. Dry bran is only very mildly laxative, chiefly when first introduced into the rations.

Preference is often shown for "broad-leaved" bran as compared with finer samples, and for white as against red bran, but there is no evidence in support of these fancies.

An Offer.

An esteemed correspondent in Australia sends us the following, which we reproduce *verbatim et literatim*.

So. St. Joseph, Mo., March 27, 1913.

University of Melbourne, Veterinary College, Melbourne, Australia.

Glasgow Veterinary College, Glasgow, Scotland.

Royal Veterinary College, London, England.

Royal Veterinary College of Ireland, Dublin, Ireland.

Royal Veterinary College, Liverpool, England.

Gentlemen of University of Melbourne, Veterinary School.

I have discovered what causes horses to go blind; that is, something over 90% of all horses that go blind. I think that this will be of some value to you, at any rate, I am going to give you an opportunity to consider it, and I am confident that the place where it belongs is in the hands of practicing veterinarians of the country.

I have found out what the cause is, the symptoms, process and results; also how to prevent it, how to treat a horse that is effected, so as to save his eyes, and it is not a difficult job.

The facts of the case are simple, the process is reasonable and very natural under such conditions that are brought about by such a cause.

If you have the knowledge of the nature of the addiction, then this affliction can be handled in an intelligent, effective manner with more assurance of satisfactory results.

You may have a barrel of remedy and it is of no material benefit, if you are not acquainted with the Hows, Wheres and Whys of this affliction.

While these are facts I am offering, you are very apt to see them as such; you can receive these facts in this state of mind.

(Truth has a way of explaining itself to the minds of some, beyond the power of man to explain) yet the undisputable fact remains that it takes time to demonstrate how well a doctor can perform his work; how well a horse owner can guard against this occurrence recurring, whether he acts in accordance with the fact as they exist to save his horses' eyes, and these are the facts to be taken into consideration.

It will take the life time of a number of horses so affected with this susceptibility on the hands of man or men, that know the Hows, Wheres and Whens and to act accordingly to prove these statements that you and I make to be undisputable facts proven beyond a doubt in this case.

If this proposition interests you and looks to be of value to you, how much will you offer for the copy-right of this information; how much of a royalty on the medical remedy will you offer, under what conditions will you consider this proposition?

It has taken me years to thoroughly demonstrate to my own mind that this discovery is a fact beyond any possible doubt.

It is necessary for horse owners to know the fact as they exist to handle this affliction, it is also of vital importance that the veterinary should be proficient in his diagnosis and his part of the work; this education of the farmer, horseowner, naturally is in your hands, You, the fountain head. This information, if wanted will be printed in pamphlet form, explaining thoroughly, in detail, the whole proposition.

I am writing this letter to all Veterinary Colleges of England Ireland, and Scotland and by you co-operating, you can get this information at an insignificant cost to any of you.

The value of this is beyond an estimate of the horse owning public.

Who is this, that is making this proposition? Will say that I am a dealer in cattle at the Stock Yards in St. Joseph Missouri, and have always dealt in cattle and horses, not only as an occupation and to make a living, but for rest, recreation and pleasure this has been my life time work.

I am 46 and have been a specialist in this one particular line of research. The first horse I ever had claim to, was when I was 9 years old, she went blind under me or near me, when I was hearing caws as a farmer boy. It took her three years to go blind, I watched this process from start to finish.

When I was 20 years I had another fine horse to go blind on my hands. In the meantime I was trading and dealing in horses. This was the beginning of the end.

This one idea, of why a horse should go blind, why it cannot be stopped, why there is not a way to stop it, was forever the uppermost subject in my mind, when it was said that the intellect of man shall prevail.

In August 1892, at Wray, Colorado, I found the key to this "Go-blind" proposition, where you cannot help your self and do all you can. Here is where I declared "War" and started it on this Moon-eyed Periodical Oph., and all other mis-leading names; but go blind just the same.

With this discovery as a key, I picked up a piece here, a part there, until I found in 1897 or possibly later, that it is easy to save the horses' eyes, while I had him under my control.

The fact of the case are, that I never failed. There is no need of failure when you know what it is, where it is, and how it works and have the remedy. Will also say that the practicing Veterinaries and Instructors in Veterinary Colleges, up and down this fair land of ours, are as innocent of the cause and process and as helpless in the act of saving horses' eyesight as a child.

I have plenty of proof of the correctness of this statement in fact too much. The blind horses of this country are visible evidence of the knowledge and how proficient, you Veterinary Men are in the treatment of this affliction. The blind horses are living, walking monuments of your failures.

This discovery has cost me years of study, and more money than most men would care to invest in such a hazardous undertaking. While these being the fact, yet this work has been a pleasure to me.

Should you want reference write the Stock Yards Bank of St. Joseph, Missouri. I am at your service to assist and co-operate all that is possible in this work if so desired.—Yours truly,
L. B. PETER.
Live Stock Exchange Building,
South St. Joseph, Missouri, U.S.A.

Anæmia due to Pediculosis.

Many of our practitioners are familiar with the effects of mange, but probably very few of them will have met with a gross infestation of macroscopic parasites comparable to the following:

Mr W. Holland (*Tidsskrift for Den Norske Lægeforening*, September 15th, 1913), records a case of severe anæmia, the only cause of which seemed to be generalised pediculosis. The patient was a painter, aged 60, who had been admitted to hospital two years earlier for anæmia and extreme debility. Frequent attacks of fainting necessitated injections of camphor and ether. The pediculi swarmed not only all over his body, but were also found crawling over his purse and goloshes, and forming large, creeping clusters. The patient's face was puffy, and the colour of his skin waxy. He suffered somewhat from cough and digestive disturbances. There was bronchitis, but the abdomen and urine were normal. A generalised rash gave a copper-like colour to the skin. After several months' treatment in hospital with potassium iodide and iron the bronchitis and anæmia disappeared, and the patient gained weight. On readmission to hospital two years later the anæmia had returned, and the pediculi were so numerous that the outside of the patient's clothes was grey with them, and the inside presented a layer of vermin several millimetres in thickness. The blood count was characteristic of secondary, not pernicious anæmia. Though the pediculi could be counted by the hundred thousand, there were no macroscopic lesions of the skin, apart from a few scratches. Possibly his age and familiarity with the vermin rendered the patient insensitive to their attacks.—*B.M.J.*

London Hackney Show.

The annual national show of hackneys, harness horses and ponies, is fixed for March 3rd, 4th, 5th, and 6th next at the Agricultural Hall, London. £1,490 will be awarded in prizes, and there are champion cups to the amount of £461. In very many of the 42 classes it is only necessary for the horse to be sired by a registered hackney.

Entries close on January 26th to Mr. Frank F. Euren, Secretary, at the Society's Offices, 12 Hanover Square, London, W., from whom all particulars may be obtained.

Docked Tails and Grazing.

Grazing for horses—with docked tails, 6d. a day; with long tails, 1s. a day.

This notice appears in a meadow near Dieppe. The owner of the meadow, when asked for an explanation of the difference in the charges, replied, "A docked horse is constantly irritated by the flies, and keeps on stopping his grazing to drive them off by swinging his head. A long-tailed horse keeps off the flies with his tail, and so can keep on grazing without interruption."—*Daily Mail*.

X-Ray Cancers and Radiation Therapy.

In a lecture before the Röntgen Society at the Middlesex Hospital on Monday, 5th inst., Dr. Jean Clunet, of Paris, described the upward growth of skin cells from within till cast off as dead scales. In cancers, he pointed out, the young cells did not age normally, but became active on their own account and multiplied. X-rays hastened the normal process, but a violent application produced a dead scale so quickly as to form an ulcer. Milder doses caused thinning and atrophy of the skin. He then explained that under strong rays the cells aged so quickly as to hinder their reproduction; very small

doses stimulated their reproductivity. Thus the small doses to which the radiographer was subject caused inflammation on which cancer sometimes supervened. Moreover, x-ray cancers were peculiarly difficult to heal. In one case, doses large enough to be destructive were given, but as the nerves became affected the treatment had to be given up.—*The Hospital*.

Fees to Inspectors.—Holland County Council.

We have been favoured with a copy of the following, with scale:—

Sessions House, Boston.

January 10th, 1914.

Dears Sir,

TUBERCULOSIS ORDER, 1913.

I am directed to inform you that the Holland County Council, Diseases of Animals Acts (Executive) Committee at their meeting on the 6th inst., adopted the subjoined scale of fees to Veterinary Inspectors, in carrying out the "Tuberculosis Order of 1913," which scale is supplemental to the existing scale of fees to Veterinary Inspectors of this Administrative County.

I am to request that you will at once signify to me your acceptance thereof, as otherwise other arrangements will be resorted to for the purpose of carrying out veterinary inspection, etc., of animals within the Administrative County.—I am, dear sir, yours faithfully,

W. H. GANE,

Clerk of the County Council.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Jan. 20.

SPECIAL RESERVE OF OFFICERS.

ARMY VETERINARY CORPS.

Lieut. C. M. Stewart resigns his commission. Dated Jan. 21.

OBITUARY

BRITTLEBANK.—On January 22nd, Ethel Holliday, beloved wife of Joseph William Brittlebank, Park View, Brooklands, Cheshire, aged 38 years.

Personal.

Mr. DAVID MCCALL, M.R.C.V.S., Johannesburg, has purchased two well-bred Clydesdale stallions, which will be shipped to South Africa. One of the horses is Buchlyvie's Pride (16501), is rising four years old, and was sired by the well-known Baron o' Buchlyvie, out of Gloria, a mare by Baron's Pride. The other horse, Burnhead Favourite, was got by The Bruce, and is a horse of superior type.

Principal McCALL, F.R.C.V.S.; Mr. ANDREW ROBB, F.R.C.V.S.; and Mr. WILLIAM LOGAN, M.R.C.V.S., Inverness, are to examine for the Scottish Stallion Show at Glasgow, which is arranged for Feb. 4th.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1334.

JANUARY 31, 1914.

VOL. XXVI.

STATE AID FOR VETERINARY SURGEONS.

On another page we reprint a report of some important utterances by Mr. Runciman upon veterinary education. They are full of hope for our profession. Mr. Runciman fully recognised the need for the financial support of veterinary education by the State, and he foreshadowed the speedy advancement of a scheme for that purpose. Thus far, his words were quite clear and definite—naturally, as the matter is still in the inception, he did not enter into details. So far as it goes, the speech appears to be the most encouraging one to veterinary surgeons that has yet emanated from a Minister of State. The British Government has been a long time in recognising the just claims of the veterinary profession, but it is evident that recognition is coming at last.

THE RESEARCH DEFENCE SOCIETY.

This Society is now commencing the sixth year of its existence, and the results of its work are well summarised by the following extract from a letter which its executive officers have sent to the public Press.

"We are of opinion that our Society has helped to bring about a much better understanding of experiments on animals in this country. There is less of ignorance, prejudice, and ill-will, less readiness to accept without inquiry the charges made against this method of research, less doubt of its great value in physiology and pathology.

The public is beginning to see that experiments on animals are useful in the maintenance of national health and efficiency, in the protection of men on foreign service, in the safeguarding of workers at dangerous trades, and in the immunising of live stock against infectious disease."

All this is true; and veterinary surgeons as medical men owe a debt to the Society. Its work is largely that of a popular educator, spreading abroad the truth regarding animal experimentation as applied to medical science in its widest aspect. In no branch of medicine has animal experimentation proved more valuable than in the veterinary; and no branch would suffer more by its discontinuance. The Society that has done so much to render its position impregnable should be able to count upon veterinary support. Curiously enough, the medical profession as a whole has never supported the Society very warmly, and the veterinary profession has scarcely noticed it. Both professions should join in supporting, for its work is now bearing visible fruit.

ENORMOUS MYXO-SARCOMA OF THE OVARY IN A BITCH.

Hebrant and Antoine, of the Brussels Veterinary School, record this case of a small fox-terrier bitch, about eight years old. She appeared in very good health, but her abdomen was abnormally developed, almost trailing upon the ground. The history was that this swelling had appeared gradually, and it was certain that the animal could not be pregnant.

At first sight the appearance indicated ascites. The abdomen was distended at its most dependent part, and the flanks were hollow; while palpation and succussion gave a very distinct impression of "surging." Further examination, however, did not support this diagnosis. No abnormality could be detected in the organs usually concerned in the causation of ascites. The heart was beating normally, and auscultation of it indicated that its function was very good. The kidneys did not seem to be involved, for a complete analysis of the urine showed nothing abnormal. The liver, although it was impossible to examine it closely on account of the abdominal tension, did not seem to be acting abnormally. Finally the abdomen was repeatedly punctured at different places, first with the needle of a Pravaz syringe and then with a trocar, but not the least amount of liquid could be obtained.

Suspecting an ovarian cyst, the authors decided upon an exploratory laparotomy, and the abdomen was opened along the linea alba, under anaesthesia and aseptic precautions.

No liquid escaped when the abdomen was opened, but a fluctuating organ, slightly bluish in colour, and in its external aspect exactly resembling that of an uterus filled with pus, appeared in the wound. The organ was so voluminous that the abdominal incision had to be twice enlarged to extract it. When extracted, it proved to be not a uterine horn but an ovary the size of a man's head, and of soft consistence. The ovarian pedicle was then ligatured, the organ was removed, and the abdominal cavity was closed. The operation was carried out entirely without hæmorrhage.

The diseased organ weighed $3\frac{1}{2}$ kilogrammes (= about $8\frac{1}{2}$ lbs.) When incised, it appeared as a gelatinous mass formed of meshes of connective tissue containing a mucoid substance, and here and there showing centres of tissue the colour of calves' flesh. A myxoma with sarcomatous centres was diagnosed, and numerous microscopical examinations proved this to be correct. The condensed portions showed the structure of a spindle-celled sarcoma, and elsewhere the tissue was that of a myxoma of very loose texture.

The post-operative progress was perfect, and the last stitches were removed on the eighth day. The bitch did well subsequently, and was well advanced in pregnancy less than four months after the operation—(*Annales de Méd. Vét.*)

PERHYDRIT, A STABLE PREPARATION OF
HYDROGEN PEROXIDE.

Dr. J. Schumacher calls attention (*Deutsche Mediz. Woch.*) to this product. Merck's "perhydrol" is a chemically pure and acid-free preparation of hydrogen peroxide. Perhydrit is a more easily manageable and more stable form of perhydrol. It is a stable combination of hydrogen peroxide with urea, and is prepared from perhydrol. It is supplied in solid form in bottles of 20 and 50 grammes, and also as one-gramme perhydrit tablets in quantities of 10, 25, and 50. As regards the effects of the hydrogen peroxide as a disinfecting agent and in the cleansing of wounds, the properties of the new preparation are not inferior to those of perhydrol.—*Berliner Tier. Woch.*

W. R. C.

A TWIN FŒTUS.

On the evening of January 14th I was called to a three-year-old heifer in parturition. From appearances observed, she had been in labour for hours and she was in a state of exhaustion.

On examination I found that it was a breach presentation of a large calf in a very small pelvic ring. On further exploration I was very surprised to find a number of feet—six or seven—which on examination were found to include both fore and hind limbs.

I drew out the first pair of hind legs, and removed part of the foetus at the loins: and did the same with the other hind limbs, cutting across the

loins. As I had previously secured some fore legs, I tried to turn what was left of the foetus and secure the head—the poll only of which could be reached.

As I saw it was a hopeless case—the heifer being exhausted and the pelvis too small to admit of a moderately sized calf being delivered—I had her slaughtered, and on post-mortem I found the bodies of two calves joined together at the side of the sternum. Their fore legs were round one another's necks in a sort of embrace, with the feet extending backwards. The union between the two bodies seemed to be made up of cartilage and fibrous tissue; but as it was freezing at the time, and I was stripped in a draughty shed, I did not stay to examine very minutely. I enclose a photograph; you will see that the hind quarters are missing.

SARCOPTIC MANGE IN THE DOG.*

By Prof. CRAIG, M.A., M.R.C.V.S., Royal Vet. Coll., Dublin

Mr. President and Gentlemen,—When I promised to read at this meeting a paper on "Sarcoptic mange in the dog," I intended to show specimens of the parasites under the microscope. It was suggested that the paper would be more interesting to you, if, in addition to this I gave a lantern demonstration, not only of the mange parasites of the dog, but also of those in the horse and sheep. Accordingly with the generous co-operation of Prof. Mettam and Mr. Haines, to whom I am indebted for much of the work entailed, I had micro-photographs made of specimens of my own preparations, and the lantern slides which I am about to show you are prepared from them. The parasites of which the photographs were taken were grown on some of the animals in this country. I have placed a series of some twenty slides under the microscopes upstairs, showing various mange parasites, for your inspection afterwards.

In dealing with the subject of mange, I shall refer in detail to sarcoptic mange in the dog, and then pass under review the acari causing mange or scabies as it affects the other two species of domestic animals.

SARCOPTIC MANGE IN THE DOG.

There are three forms of mange in the dog—Sarcoptic mange, Follicular mange, and Symbiotic mange affecting the ears causing acariasis or parasitic canker. Of these, indeed of all skin diseases of the dog, the most common is sarcoptic mange. That conclusion is the more forced upon one when a systematic examination is made of the scrapings of the lesions in all skin cases observed in practice. On many occasions difficulties may arise in discovering the cause of the disease, but with practice the parasite in one or other of its stages may easily be found as a rule, in sarcoptic mange, when one becomes familiar with the lesions in which the acari are likely to be present. That is my own experience. At first I had the greatest possible difficulty in demonstrating the parasites in sarcoptic mange, but now I am usually able to do so without much loss of time.

* Read at the meeting held on Dec. 10th.

Occurrence. Sarcoptic mange affects dogs of all breeds and of various ages. I have seen a great many cases lately in young dogs. One of the last cases I had appeared in a Pomeranian puppy only four weeks old. At the time the puppy was brought to my notice the disease had extended nearly all over the body, pointing to infection shortly after birth. No information could be obtained as to the source of infection; the owner told me that the dam was apparently quite healthy.

Etiology. The cause of the disease was first demonstrated by Grohier in 1814, and has since been described by Gurlt and Hertwig, Gerlach, Fürstenburg, Robin, Delafond, Mégnin, and others. It is a variety of the *Sarcoptes Scabiei*.

The *Sarcoptes Scabiei* belong to the Psoric Sarcopitidae of the order Acarina and the class Arachnida. It is white or grey in colour and almost microscopic in size. The body is oval, convex on its dorsal surface and flat below. (Photos 1 and 2). It is covered with a fine chitinous envelope which is marked by fine sinuous streaks and presents bristles and spinules at various parts. In front, the mouth parts (maxillae, palps, mandibles) form a stout conical rostrum which is flanked on either side by a thin expansion, the cheek, giving it a somewhat horseshoe-like appearance. The limbs are very stout and short and number four pairs in the adult, two pairs being attached to the body at the side of the rostrum and two pairs under the posterior portion of the body. The two posterior pairs are so completely covered that they cannot be seen when the sarcopt is viewed from the dorsal surface. Their presence then is only indicated by the long bristles which extend beyond the margin of the body from the extremities of the limbs. On the dorsal surface there are two long spinules behind the rostrum, three strong spinules in a triangle behind the second pair of legs on each side, seven spinules disposed in two rows on each side of the anus, and four hairs projecting backwards from the posterior margin of the body. The anus is terminal. Some of the limbs end in ambulatory suckers. The sucker is a slight membranous expansion, tulip shaped, attached to the end of the limb by a long thin stalk. The adult female is provided with suckers on the first two pairs of limbs, the adult male on the first two and fourth pairs. The other limbs end in long bristles. The adult female of the *Sarcoptes scabiei* v. *canis* is about .35 m.m. long and .26 m.m. broad, the adult male is .2 m.m. long and .15 m.m. broad. According to Mégnin the varieties of sarcoptes may be distinguished by their size, but the specimens which I have measured in the horse and dog correspond very closely.

Sarcoptes Notoedres. In three cases of mange which I examined in the dog this year, the sarcoptes present was the *Sarcoptes notoedres* (or *Sarcoptes minor*) of the Subgenus *notoedres*, varieties of which commonly cause sarcoptic mange in the cat and rabbit. This parasite is easily recognised among the sarcoptes by the following features. It is much smaller than the ordinary sarcoptes, its body is nearly spherical, the streaks on the upper surface of the envelope form concentric rings, the anus lies on the dorsal surface, and on each side of it there are six instead of seven spinules. (Photos 2, 3, 4, and 5). The average size of the specimens which I have examined are for the female .21 m.m. long and .15 m.m. broad; for the male .14 m.m. long and .1 m.m. broad. The eggs are .1 m.m. long and 0.7 m.m. broad. In the first case the dog was an aged mongrel and the lesions were confined to one side of the face. The hair was removed over a considerable area, the epidermis was greatly thickened and presented an appearance similar to the surface of the dog's pad. The excess of epithelium could be easily scraped off. Numerous parasites in various stages of their development were found in the lesions. The eggs were packed together

in what appeared to be nearly straight galleries, almost vertical to the surface of the skin.

The second case was a black and tan terrier about two years old in good condition. Hair was removed in patches from various parts of the head, around the eye, face, forehead, and almost entirely from the external ear. The skin over these areas was slightly thickened and wrinkled. Epidermal thickening was especially marked at the edge of the external ear. There were no other lesions. In scrapings from the edge of the ear female parasites and their eggs were extremely numerous. No evidence could be obtained in either case of the source of infection; possibly it was a mangy cat.

Third case of Sarcoptic mange in the dog due to the *Sarcoptes Notoedres*. Since writing this paper I have observed a third case of sarcoptic mange in the dog due to the *Sarcoptes notoedres*. The affected animal was an Irish terrier dog, two years old, in fair condition. It had only recently recovered from distemper. For about a week it had been noticed scratching its head, ears and elbows very much. Over these areas the skin was becoming very thin and a few ulcers had resulted from the scratching. A little epidermal thickening had formed on the skin at the side of the outer canthus of the right eye. This was scraped off and examined. It contained numerous specimens of the *Sarcoptes notoedres*, chiefly females and their eggs. The dog was said to have been in the habit of playing up to two or three weeks previously with a cat which had some affection of the skin of the head, probably sarcoptic mange.

Development of the *Sarcoptes*. The ovigerous female by means of its strong rostrum burrows into the epidermis and forms a gallery which may be straight or curved. This gallery it may make in as short a time as 24 hours. In places where the skin is thin and unpigmented the entrance to the gallery appears as a dark spot on a slight elevation. In the gallery the parasite soon begins to lay its eggs.

The Egg is ovoid in shape and about .15 mm. long and .08 mm. broad. Its contents are granular and it is covered by a thin homogeneous tough envelope. The number of eggs laid vary from 19 to 40, 15 probably being an average number. (Photo 6). I have counted as many as 50 eggs in one gallery on several occasions. Frequently only five or six eggs may be found in the neighbourhood of an ovigerous female. In the egg sometimes the larva may be noted in various stages of its development. (Photo 7). Before hatching out it lies in the egg with the bristles of the posterior limbs curved round the posterior part of the body. The larva hatches out in from three to eight days and leaves the gallery. Mégnin states that under most favourable conditions this may take place in 24 to 48 hours. The shell of the egg from which the larva escapes is split vertically at one end and has the form of an opened oyster shell; it is fairly characteristic.

The Larva is very small. It is provided with three pairs of legs, the two anterior pairs carrying suckers, the posterior pair bristles. It becomes quiescent and moults on two or three occasions to allow of its increase in size. (Photo 8 and 9). On the last occasion it becomes changed in a nymph.

The Nymph is much smaller than the adult, it is provided four pair of legs similar to those of the female, but the sexual organs are not developed. (Photo 10). It soon moults and is converted into the

Adult, Male or Female. The adult males are few in number and are much smaller than the females. The females when first formed are said to be pubescent. After coupling with the males, they moult and become changed into the ovigerous females which are provided with a vulva behind the anterior limbs on the ventral aspect. In each female as a rule only one egg may be seen. These changes occupy a period of two or

three weeks. Gerlach regards the average time for development as 15 days and the average number of progeny as 15 individuals, five males and ten females. He therefore estimates that from one ovigerous female $1\frac{1}{2}$ millions may be produced in 90 days, thus indicating the enormous increase in the number of parasites and consequent development of mange that may occur within a very short period.

Resistance of the Sarcoptes. It is of great practical importance to know the longevity of the parasite removed from its host. How long will the sarcoptes live when removed from the skin? A few observations have been made to elucidate this question. According to Gerlach the sarcoptes of the horse die in a few days in dry air, but live for about a fortnight if kept moist. In specimens from the dog which I have kept on several occasions the adult acari and their eggs begin to break up after five days although kept warm and fairly moist. It is quite possible that in certain circumstances the sarcoptes may live in infected kennels or stables longer than these observations would indicate, but probably not longer than three or four weeks. As for the action of various agents on the acari, observations have been made under the microscope to note when the acari become quiescent after the agents had been applied, and their power of infectivity has also occasionally been tried. The parasites are quickly destroyed by exposure to a temperature near boiling point, by 10 per cent. creosote, carbolic acid, oil of tar, Peruvian balsam, bi-sulphide of carbon, creolin, tincture of iodine, petrol, oil of turpentine, potassium sulphide, 10 per cent. caustic potash and soft soap. The efficiency of these drugs in practice as parasitocides depends on their power of penetration, and their suitability is related to their toxicity and other circumstances.

Transmission. Sarcoptic mange is chiefly transferred by direct contact with affected animals, and this is the more likely if the disease is advanced. Dogs may also, but less commonly contract the disease from infected litter, by introduction to infected kennels, from attendants, by clothing and brushes. Animals which are frequently groomed and washed are less liable to become affected.

Method of Action of the Parasites. The sarcoptes produce their symptoms by irritation of the skin through biting, burrowing into the epidermis, but chiefly through the excretion of some irritating substance. This latter method of action has been well shown by an experiment of Gerlach. With a very fine needle he traced a groove in the epidermis and then moistening the point of the instrument with fluid from a crushed parasite re-introduced it into the groove. When the dermis was reached there was instantaneous pain, succeeded by the appearance of a papule and vesicle with pruritus.

Period of Incubation. The interval between infection and the appearance of noticeable symptoms varies with the number of acari which find their way on the body of the host, and also upon their vigour. In moderate infection the condition is not noticed for two or three weeks.

Symptoms. One of the first symptoms noticed is pruritus, the dog frequently scratches itself with the hind or even the fore limbs, rubs its body against neighbouring objects and bites itself. It presses very firmly against the hand or brush which is applied over its skin and when the skin is scraped, the dog makes vigorous scratching movements with its hind limbs. The intensity of the pruritus varies with individuals, is greater in thin-skinned animals, but not invariably so, is not so marked in puppies as in older animals. It may depend on two factors, the irritability of the skin and the potency of the excretion of the sarcoptes. It does not

appear to be related so much to the number of parasites; in some cases I have noted the parasites were easily found, although the irritation was not very great. The pruritus is markedly increased when the dog becomes heated. This is due to the increased activity of the sarcoptes. (Photo 11.) The first part of the skin usually invaded is the head. The lesions there appear around the eyes, on the face and the outer side of the ears. They extend from the head into the intermaxillary space and to the neck. By scratching and rubbing, the parasites are transferred to the hind and fore limbs, and also to the under aspect of the thorax and abdomen, and lesions appear in these situations. On the limbs the lesions are most marked at the back of the elbow and above the hock. In severe and old-standing cases the disease involves the back and ultimately the whole body. In the early stages the epidermis over small areas becomes roughened, thickened, lumpy and scaly and the hair is cast off. The patches are irregular and increase in size at the edges. Little nodules

ings, about the size of a pin's head or more, sometimes be seen and felt. Where the skin is unpigmented, it is slightly reddened and a little dark spot may be seen on the centre of each nodule. This is most commonly noticed on the abdomen and side of the chest in thin-skinned dogs. The nodules are chiefly of epidermal formation, and indicate the point of burrowing of the ovigerous female sarcoptes. The parasite may be found if a deep scraping be taken over these spots. Occasionally small pustules about the size of millet seeds or larger, develop especially on the abdomen, as the result of the biting or piercing of the skin by the parasites, but I have never been able to discover a sarcopt in the pustules. Later the skin became very scaly, and large thin grey epidermal flakes are cast off or remain partly adherent to the neighbouring hairs. In cases where the skin around the eyes is involved and becomes denuded of hair, the dog presents a lemur-like cast of features. As a result of the thickening of the skin in that region, the eyelids may be slightly intumed and a conjunctivitis with a purulent discharge sets in. The thickening of the epidermis is usual greatest at the points where the dog cannot scratch or rub properly, e.g. the forehead, the tips of the ears, and these are the places from which scrapings should be taken for the purpose of examination. On account of the scratching, some areas of the skin such as at the side of the head, behind the elbows, and under the abdomen and chest, become reddened, moist and ulcerated. These ulcers may bleed and afterwards become covered with black scabs. In some cases there is a peculiar odour of the skin, almost like that of urine. As a result of the restlessness produced by the parasite and its excretion, the animal soon loses condition and may even become emaciated and very weak. The skin becomes greatly thickened and wrinkled. In neglected cases the dog may die from exhaustion after some months.

The progress of the disease is retarded by good grooming, frequent washing, and a generous diet, but is hastened by debility, poor condition, and bad hygiene.

The diagnosis is rendered probable by the appearance of the symptoms above described, especially by the pruritus and the situations of the lesions, but it is only absolutely certain when the parasite is discovered. In most skin diseases nowadays I am never satisfied with my diagnosis until I have made a microscopic examination of scrapings of the skin. The method I adopt is as follows: I note the parts of the skin where the epidermis is thickened and rough, almost wartlike. From these parts I scrape off the epidermis until the corium is exposed and the surface becomes moist or bleeds. It is as a rule of no service to take scrapings from the skin which is congested but not thickened either at the edge of the lesions or elsewhere, or to

examine the scales detached from the skin but adherent to the hairs, or the scabs of blood which have formed over the ulcers, the result of scratching. I then mix the scrapings with a 10% watery solution of caustic potash or soda on the surface of a slide, or better, rub them together in a small mortar, but use only sufficient alkali to make a soft paste. The alkali softens the scrapings, renders them transparent but does not act upon the chitinous covering of the parasite or its eggs. The material may be examined after a few minutes, but it is best to wait for half-an-hour or more to allow of the more complete action of the alkali. The mixture is then spread in a thin layer over a clean slide, and a second slide pressed firmly down over the scrapings to flatten them out. This makes the film sufficiently clear for a microscopic examination. The preparation is then placed on the platform of the microscope and examined with a magnification of 40 or 50 and with a moderate light, such that the contour of the epithelial scales are appreciable. The preparation is then subjected to a systematic scrutiny and if necessary the whole of it examined. The examination only occupies a few minutes. Sometimes it is necessary to search several preparations before the parasite can be discovered. As a rule it will be found in one or several of its stages, sometimes an egg or two, perhaps containing larvæ, sometimes one or several free larvæ, nymphs or adults; generally the latter are females, males are seldom seen. The discovery of the parasite is most difficult when the cases have been previously treated. The following is a list of a dozen cases, giving the age of affected animals and the results of microscopic examination.

Breed.	Age.	Parasites found.
Scotch collie	6 mos.	1 female, 1 larva, several eggs
Black pom.	4 wks.	2 females and nine eggs
Irish terrier	4 mos.	1 female
Scotch collie	adult	1 ovigerous female, several eggs
Yorks. terrier	5 mos.	1 female
Collie	5 "	several adults, larvæ, eggs
Irish terrier	3 "	2 females
Chocolate pom.	7 "	4 eggs containing larvæ
Fox terrier	3 yrs.	several adult sarcoptes
Irish "	2 "	1 female
Mongrel "	aged	1 female and 1 egg
Irish "	9 mos.	several sarcoptes, adults, [larvæ.

It has been recommended that the mixture of scrapings and alkali be centrifugalised previous to examination, but that can only be of service if a large quantity of alkali be used in the first instance.

Differential Diagnosis. Several skin diseases may be distinguished from sarcoptic mange by their symptoms and the result of microscopic examination. The following may be noted:—

Follicular Mange often attacks the same areas as in sarcoptic mange. It is not, however, accompanied by much itching. In the purulent form the small worm-like demodex may be easily discovered in films of pus from the minute abscesses. (Photo 12). In large abscesses with blood stained contents the parasites are difficult to find. In the squamous form in scrapings of the thickened epidermis treated as for sarcoptic mange the small demodex is easy to demonstrate.

Ringworm is uncommon in the College practice. It is accompanied by little or no pruritus and the lesions are circular in outline. Scrapings are taken and treated as for mange, but the hairs must be particularly examined. On a slide a thin film is made, covered with a cover glass and examined under a fairly high power, 200 to 500. The broken condition of the hairs may be noted and the round colourless spores of the

trichophyton identified near the broken ends in or around the hairs.

An Itchy Condition of the skin of the back and butt of the tail is noticed frequently in adult dogs. The skin is often scaly, wrinkled, reddened, and the hair may fall out in patches. No parasites can be found in the lesions. Many cases of skin diseases that are diagnosed as eczema are no doubt affected with sarcoptic mange.

I need hardly refer to *Symbiotic Mange* which affects only the inner side of the external ear. The parasite which causes it is commonly called the symbiotes auricularum but more properly the otodectis cynotis. (Photos 13 and 14). These parasites may often be seen with the naked eye as grey specks moving over the brown crusts when the inner surface of the external ear is examined. The cases are not nearly so numerous in the dog as in the cat.

The Harvest Bug occasionally causes much pruritus in the dog.

Treatment of Sarcoptic Mange. Attention should be paid to the complete isolation of the patient to prevent the spread of the disease to other dogs. Whatever treatment is applied, the chief secret of success is thoroughness in its application. One sometimes considers the desirability of clipping off the hair and certainly in long haired dogs the clipping of the coat facilitates treatment, but this need not be done unless the case does not improve. I have the dog first washed thoroughly with soap and water in order to remove the scales and the excess of epidermis. The kind of soap used, I do not think matters, so long as it is carefully rinsed off afterwards. I usually recommend a hard soap. The dog is then dried and a parasiticide dressing applied. I commonly use a dressing consisting of sulphur sublim 2 parts, oil of tar, potassium bicarb aa 1 part and lard 8 parts. This ointment is well rubbed into and around the lesions, a much greater area than is apparently involved being dealt with. When there is any doubt as to the extent of the disease, the whole body is treated. In the latter case, during cold weather, the ointment is applied to one half of the body one day and to the second half the following day. The ointment is applied again on the third day and the animal washed at the end of the week. The bedding of the kennel is destroyed, a little 1 per cent. solution of Jeyes' fluid sprinkled over the floor and walls and new straw or other bedding laid down. This is done every week till the animal recovers. The itching soon ceases. The skin, however, remains scaly and the hair continues to fall out for a time. This treatment is continued till the new hair begins to appear. The skin is usually quite normal again in three or four weeks. During treatment the dog is allowed a generous diet, and if the weather is cold, kept warm and comfortable. The treatment of such cases is always most difficult in cold weather. In refractory cases tonics such as liquor arsenicalis may be given internally, in addition to the external treatment. As for the medicinal agents used, care should be taken to apply no dressing that is likely to be poisonous. The dressing may be licked off and swallowed. On that account mercurial, creosote and carbolic preparations should be avoided. Sulphur and oil of tar are effective parasiticides which have no serious effect upon the patient. The alkali may ensure greater penetration of the active agents to allow of their reaching and destroying the parasites, and in the form of an ointment these agents are more intimately incorporated with the skin. Because of a deficiency in this respect watery dressings are not so efficacious. Of other preparations used Huytra and Marek employ the following dressing: Oil of tar, soft soap aa 1 part, alcohol $\frac{1}{2}$ to 10 parts. Friedberger and Frohner recommend cresol in the form of—cresol, soft soap aa

1 part, alcohol $\frac{1}{2}$ to 10 parts. Peruvian balsam dissolved in 1 to five parts of alcohol may be applied with success in mild cases of the disease in small dogs, is pleasant to use but is expensive.

After recovery of the animals, the bedding should be burnt, the kennels disinfected with boiling water or 2 per cent. creolin or other strong disinfectant and the utensils, brushes, clothing, boiled or immersed in some reliable disinfectant fluid.

Danger of Transmission of Sarcoptic mange of dogs to other animals and to man. Finally I may refer to the transmissibility of sarcoptic mange of the dog to other species of animals. The *Sarcoptes scabiei v. canis* has the dog only as its permanent host, but occasionally it may find its way to and produce temporary effects in other animals and in man. According to Zürn the sarcopt of the dog can be conveyed to the pig and horse. Occasionally the owner of a mangy dog tells us that his or her hands have become very itchy and little nodules may be seen between the fingers or on the arms.

On one occasion a woman brought to my notice a dog affected with sarcoptic mange. She told me that she was accustomed to allow the dog to sleep in her bed and that the skin of her abdomen and breast had become itchy and reddened. After application of the ointment which was used also for the dog, the affection soon disappeared. The appearance of canine scabies in man has been recorded by Grogner in a student after treating a mangy dog, by Viborg in a man and a woman who possessed an affected animal, by Beit in a child, by Hertwig, by Delafond in a student and himself. Many cases in human beings have been seen by Friedberger and Fröhner in Germany. Gerlach transmitted the disease artificially from the dog to man. In many of the cases recorded, recovery only took place after the application of a parasiticide dressing.

DESCRIPTION OF PHOTOGRAPHS.

1. *Sarcoptes Scabiei v. canis*. Oviparous female—ventral aspect. Contains one egg obliquely placed between last two pairs of legs. The parasite is so transparent that the spinules on the dorsal surface can be seen.
2. *Sarcoptes Scabiei v. canis*. Male—ventral aspect. The ambulacral suckers of the two anterior pairs of limbs are folded backwards.
3. *Sarcoptes Notoedres* (dog). Female—ventral aspect.
4. " " " " dorsal aspect.
5. " " " " Male above, young female below; one empty egg at right side.
6. *Sarcoptes Notoedres* (dog). Eggs from one gallery.
7. " " " " Egg containing larva fully developed.
8. *Sarcoptes Notoedres* (dog). Two free larvæ—ventral aspect.
9. *Sarcoptes Notoedres* (dog) One free larva—more highly magnified than (8).
10. *Sarcoptes scabiei v. canis*. Nymph—ventral aspect.
11. Collie affected with sarcoptic mange. Lesions marked round the eyes and on hind limbs.
12. *Demodex Folliculorum* (dog).
13. *Otodectes Cynotis* (dog). Female—ventral aspect.
- " " " " Male—ventral aspect.

The CHAIRMAN: We have all listened with pleasure and profit to Prof. Craig's interesting paper, and I am sure that several members will be able to contribute something to the discussion on this very important subject.

Mr. WATSON: This is a subject of great importance, and it has been dealt with by Prof. Craig in the extremely able way that characterises all his handling of such questions. But in view of the importance of the subject I do not think that at this late hour we could

do justice to the paper in any discussion that might ensue. I therefore propose that we adjourn the discussion until our next meeting in May. By that time the paper will have been printed and circulated and we will be in a much better position to do the justice to it that it deserves.

Mr. NORRIS: I have very much pleasure in seconding the motion. Would you allow me to mention one point that might be of use? Prof. Craig mentioned the great difficulty in finding these parasites in some specimens sent to him. Now, I have some little experience in examining material sent in for microscopic diagnosis. I have found great difficulty owing to the material not being properly procured. It only gives men a tremendous lot of trouble and worry for nothing, examining specimens not properly collected. I think that practitioners should be instructed that when sending in material they take every precaution to adopt the correct procedure in obtaining the specimens. A great deal depends upon the selection of material for the microscope.

The CHAIRMAN: Is it your wish that this discussion should be postponed for a future meeting? Does that meet with your unanimous approval?—Yes.

Mr. HENEY: I think it is a very poor compliment to the lecturer to suggest that this discussion should be postponed for about six months. We have about half-an-hour to spare, and it might be better to discuss the matter to some extent and then postpone further discussion, if it be your pleasure to do so. It is not fair to us that the scientific part is left to the end, and that three-fourths of the time is occupied in arguing small matters.

Mr. WINTER: I think that an adjournment of the discussion is the very highest compliment we can pay to the lecturer.

Mr. WATSON: It is meant as a compliment to him.

Mr. WINTER: I heartily approve of the adjournment. We could not possibly have a discussion lasting half-an-hour that would do justice to the paper.

It was eventually agreed that the discussion on the paper should take place at a subsequent meeting.

SOUTH EASTERN VETERINARY ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The second annual general meeting was held at the Royal Mount Ephraim Hotel, Tunbridge Wells, on Thursday, January 15th. Mr. James Crowhurst (F), Canterbury, presided, and the members present included Prof. Wooldridge (F), London; Messrs. E. Lyne Dixon, Margate; Percy Gregory, Tonbridge; Elmer Ebbetts, Rochester; Cecil Crowhurst, Maidstone; J. H. Ripley, Hurst Green; A. C. Burton, Battle; T. A. Huband (F), Hastings; J. B. Dier, East Grinstead; W. Caudwell (F), Chertsey; H. P. Hogben, Folkestone; T. F. Hogben, Ash; P. J. Austin (F), Pembury; D. R. Chalmers, Tunbridge Wells; T. Hibbard, Gillingham; J. Basil Buxton (F), London; E. W. Morris, Uckfield; G. Fordham, Ashford; W. R. Emery, Guildford; W. W. Gulliford, Lympne, Hythe; G. H. Livesey, Hove, President, Southern Counties Division, N.V.M.A.; W. H. Brown, South Kensington; A. Whicher, Bexhill-on-Sea; J. M. Richardson, Deal; E. M. Perry, Eastbourne; Septimus Dixon, London; Theo. C. Toope, Dover, hon. secretary and treasurer; and two or three others who omitted to sign the attendance book.

The minutes of the last meeting, which were taken as read, were adopted.

ELECTION OF OFFICERS.

Mr. T. A. HUBAND said he had very great pleasure in proposing the election of their friend Mr. E. Lyne Dixon, as President of the Association for the ensuing year. When Mr. Toope was proposing the formation of that Society he very kindly asked him (Mr. Huband) to give what little help he could, a request which it had given him great pleasure to respond to. He was more than pleased that Mr. Toope's efforts had been so successful. Two names were very prominent at that time, one was the name of a gentleman very highly esteemed in Kent, and the other was equally highly esteemed in Sussex. He regretted to say that one was no longer with them. He referred to the late Richard Roberts, and they deplored his loss, but the other remained, and it was his proud privilege, and he was sure all the members would support him in his proposition, to move that their friend Mr. Dixon be elected President for the ensuing year. He did not like saying things in praise of a man while in his presence, but Mr. Dixon and he were college chums and had been good friends ever since, and the longer he had known Mr. Dixon the greater had become his respect and esteem for him. He had great pleasure in asking them to elect Mr. Dixon as President of the South Eastern Veterinary Association for the ensuing year.

Mr. JAMES CROWHURST, the retiring President, said he rose with great pleasure to second the proposition. It would have been his privilege of putting that proposition before the Council when they met to consider the question of officers for the ensuing year, but unfortunately through some mistake he failed to receive a notice of the Council meeting, and was therefore not present. He had, however, previously spoken to Mr. Toope and recommended strongly that Mr. Dixon should be his successor. He (Mr. Crowhurst) felt convinced that the interests of the Association would be in good hands if they elected Mr. Dixon as President. Mr. Dixon's views and his own were much in accord, and he was sure the good work done in the past would be carried on with considerable benefit to that Association. He felt it desirable that a successor should be nominated, and that the honour of being President should not be held by one too long. He had been elected for a second year, and he thought that was more than he should have accepted, he felt very strongly that it was desirable that the honour should be passed round, for he believed in that way it was beneficial to the Association.

The motion was carried unanimously, and on taking the Chair Mr. Dixon was given a most cordial reception.

Mr. DIXON said his first duty was the very pleasant one of thanking them most sincerely for their unanimous vote in electing him as President of that Association. Not knowing for certain whether any other gentleman would be nominated, or whether he should be elected or not, he had not prepared the usual presidential address to deliver that day, and in view of the work there was to be got through he thought perhaps it was better that that was so, but it would be his pleasure to read his address at the next quarterly meeting wherever that might be held. He could not but refer in the first place to the good work that that Association, although so young, was doing for the veterinary profession. He thought that they were unanimous one and all as was evidenced by the large gathering they had that day, and that they were all anxious that matters appertaining to their own interests should be safely guarded. He thought by the correspondence that Mr. Toope had had with regard to the insurance companies' fees was evidence of that. If when they were combined they could not get things righted, how could they have done anything individually? It was only by united efforts and by remember-

ing the motto of their College that "Unity is strength" could they expect to get that which they desired. During the past two years the position of President of that Association had been held by Mr. James Crowhurst, who was a highly esteemed member of the Kentish practitioners, and they all knew that he had carried out the duties most satisfactorily, with credit and honour to himself and in the best interest of the Society of which he was President. He (Mr. Dixon) would endeavour, as far as possible, to follow in Mr. Crowhurst's footsteps, and to do what he could to carry out the duties the members had put on him faithfully, zealously and to the best of his ability. He could only say he wished all the members a happy and prosperous New Year, and he hoped that Association might flourish and prosper, and he hoped by united action they would be able to further and better the conditions which they all had so much at heart.

Vice-Presidents. Messrs. J. Crowhurst, W. Caudwell, W. H. Crowhurst, P. Gregory, T. F. Hogben, and E. W. Morris were elected on the proposition of Mr. T. Hibbard, seconded by Mr. Emery.

The Council of the Association was elected, on the motion of the President, seconded by Mr. Buxton, to consist of the following:—Messrs. J. B. Dier, G. W. Dunkin (Canterbury), C. Crowhurst, Elmer Ebbetts, F. C. Gillard (Folkestone), T. Hibbard, T. A. Huband, J. W. Richardson, and J. H. Ripley.

Inspectors' Committee. This Committee was elected as follows:—The President, Vice-Presidents, Messrs. J. B. Dier, C. Crowhurst, Elmer Ebbetts, T. Hibbard, and J. H. Ripley, on the motion of Prof. Wooldridge, seconded by Mr. Emery.

Hon. Secretary and Treasurer. The President proposed the re-election of Mr. Theo. C. Toope. In doing so, said no words were required to recommend that motion to their notice. They all knew what a worker Mr. Toope was and how he had the interest of the Association at heart.

Mr. JAMES CROWHURST, in seconding, said he had had some experience of Mr. Toope's work from the inception of that Association, and he was sure they were very fortunate indeed in having as Secretary a man who had given and was prepared to give so much time and attention to the work of that Association. They could not possibly have a better man than Mr. Toope in every way. (Applause).

Mr. TOOPE briefly acknowledged the compliment.

Hon. Auditor. Messrs. H. P. Hogben and G. W. Dunkin, were re-elected, on the proposition of Prof. Wooldridge, seconded by Mr. Gregory.

NEW MEMBERS.

Mr. BURTON, Battle, was proposed by Mr. Ripley, and seconded by Mr. Morris, for election as a member of the Association.

Mr. T. CLYDE, Dover, was proposed by Mr. Toope, and seconded by Mr. Richardson.

Mr. PERRY, Eastbourne, was proposed by Prof. Wooldridge, and seconded by Mr. Gregory.

All three were duly elected.

NOTES AND OBSERVATIONS ON TWENTY CASES OF TUBERCULOSIS.

WILLIAM CAUDWELL, F.R.C.V.S., Chertsey.

Mr. President and Gentlemen,—A few weeks ago it occurred to me that if our zealous secretary had not much on the tapis for this meeting he might accept an offer from me to read a few notes to you on cases that I have dealt with under the Tuberculosis Order of 1913, and I take this opportunity to thank him for placing the matter on the agenda.

It is with some diffidence that I submit these notes for your consideration, inasmuch as I feel that many of

you who are inspectors have had a much larger experience of the disease than myself, and have also dealt with a larger number of cases under the Order, but I trust that an interchange of experiences will prove helpful to all of us.

I have divided my cases into two categories, first those which I confirmed by clinical and other evidence, and second those which were not confirmed. The number of each case corresponds with the number in my report.

CASES OF TUBERCULOSIS.

Case 2. Cow in milk.

Symptoms. Emaciation, coughing frequently, accelerated respiration, crepitation in both lungs, temperature 105°. The owner declined his consent to apply the tuberculin test, and eventually he had her slaughtered.

Post-mortem appearances. Both lungs are in a condition of advanced tuberculosis, the left costal pleura is thickened with tuberculous growths. The mediastinal and bronchial glands are much enlarged. The dorsal, mesenteric and hepatic lymphatic glands are tuberculous. The liver is also tuberculous.

Case 3. Cow in milk, six years old. She calved ten weeks ago.

Symptoms. Emaciation, temperature 102.3°, coughs occasionally, crepitation in the left lung, induration of the right posterior quarter of the udder. I obtained a sample of milk from the diseased quarter and made a microscopical examination but failed to find any acid-fast bacilli. With the owner's consent I applied the tuberculin test, and a reaction followed, the temperature having risen 4° about the 13th hour after the injection.

Post-mortem appearances. Carcase emaciated, milary tuberculosis of both lungs. The bronchial and mediastinal glands are much enlarged and caseous. The hepatic glands and the liver are also tuberculous.

Case 4. Cow in milk, five years old. She calved a few weeks back.

Symptoms. She is emaciated, and has a slight cough, the right half of her udder is much enlarged, hard, nodular and painless, and the right supramammary lymphatic gland is also much enlarged. I took samples of milk from the diseased quarters, and on making a microscopical examination I found acid-fast bacilli in the smears.

Post-mortem examination. The right half of the udder weighs 28 lb; it is very firm and cirrhotic, and contains small tubercles throughout. The right supramammary gland is 5 inches long. The left half of the udder appears to be normal and weighs 7 lb. Both lungs are tuberculous, especially in the anterior lobes, and the pleura is thickened. The bronchial and mediastinal glands are enlarged. The mesenteric glands are much enlarged and caseous. The hepatic glands are slightly diseased. The liver is free from tubercles, but its ducts contain some flukes. The spleen and kidneys are healthy. The right lumbar lymphatic glands are much enlarged. Both horns of the womb are tuberculous, the cotyledons are of a bright yellow colour, and the smears which I prepared from them are very rich in tubercle bacilli. A smear from the muco-purulent fluid contained in the womb shows only a few tubercle bacilli.

Case 5. Cow in milk.

Symptoms. Body emaciated, udder apparently healthy, eyes sunken, frequent cough, crepitation in the right lung. Temperature 105°. I tested the animal with tuberculin by injecting 50 minims subcutaneously, and I applied the ophthalmic test at the same time. At the 12th hour a bead of muco-pus had appeared in the inner canthus of the eye, accompanied with a flow of tears.

Post-mortem appearances. The pharyngeal, bronchial and mediastinal glands are enlarged and caseous, and both lungs are extensively tuberculous. The hepatic and gastric lymphatic glands are slightly enlarged. The

spleen and liver are healthy. One kidney contains small tubercles. The supramammary lymphatic glands also appear to be slightly tuberculous, but the udder seems to be normal.

Case 7. Cow in milk, five or six years old.

Symptoms. Very emaciated, coughs occasionally, crepitus in both lungs; right supramammary gland is enlarged, and the temperature is 103.8°.

The owner decided to have her slaughtered without reference to compensation.

Post-mortem appearances. The lungs are in a very advanced condition of tuberculosis, and the bronchial and mediastinal glands are much enlarged and caseous. The lungs weigh nearly 48 lbs. The parietal and visceral pleurae and also the peritoneum show extensive tubercular proliferations. The pharyngeal and the hepatic glands are enlarged. One horn of the womb is also tuberculous.

Case 11. Cow in milk, seven years old.

Symptoms. Emaciation, coughing, crepitus in both lungs, tenderness and grunting is evinced on percussing the chest. Temperature 101°. The udder is indurated in its right front and left hind quarters. I found no acid-fast bacilli in the milk.

Post-mortem appearances. Carcase much emaciated. Both lungs extensively tuberculous, some of the lesions are old and caseous and others are recent. The bronchial and mediastinal glands are much enlarged and caseous. Liver and spleen normal. A lobule in one of the kidneys contains some small tubercles. The mesenteric glands are much enlarged. Both horns of the uterus are tuberculous, one is diseased to a greater extent than the other; both contain a quantity of thick, white, tenaceous mucus, the cotyledons are enlarged, the walls are thickened with tuberculous growths, and numerous tubercles stud the mucous surface.

Case 13. Cow in milk.

Symptoms. She is very emaciated and coughs; auscultation reveals crepitation in both lungs; her appetite is very bad, and she has profuse diarrhoea. The owner states that she has reached her present condition within a few weeks. Her temperature is 104°. I injected a dose of tuberculin subcutaneously and instilled into the eye a few drops of eye tuberculin. A reaction followed the eye test. I prepared smears from the faeces for microscopical examination and I found acid-fast bacilli in them.

Post-mortem appearances. Both lungs are extensively diseased, and are very large and heavy. Some of the sections show calcification. The bronchial and mediastinal glands are much enlarged, and the pleurae and peritoneum are "grapy." The hepatic and left popliteal glands are tuberculous. One horn of the womb is much diseased throughout its extent, and its wall is an inch thick. The other horn is only slightly tuberculous. Both kidneys show small tubercles in some of their lobules. The liver, spleen, and udder are apparently normal. A prepectoral gland which was felt during life to be enlarged is tuberculous.

Case 14. Cow in milk, 2½ years old, calved eight weeks ago.

Symptoms. She is emaciated and coughs, her temperature is 102°, appetite poor, crepitation in both lungs, especially the right, bowels normal. I am informed that this animal has recently been tested, so I applied the double tuberculin test, and a good reaction followed.

Post-mortem appearances. The bronchial and mediastinal glands and both lungs are in an advanced stage of tuberculosis. The visceral and parietal pleurae are thickened. The mesenteric and the hepatic glands are much enlarged. The liver and both kidneys are slightly tuberculous. The spleen is normal. The womb has recently become impregnated, despite the animal's advanced condition of tuberculosis.

Case 15. Cow in milk, 9 or 10 years old.

Symptoms. She is much emaciated and coughs frequently, breathing accelerated, appetite moderate, temperature normal. Crepitation is audible in both lungs, the faeces are normal. A tumour as large as a cob nut is visible, and is felt attached to the rumen in the angle formed by the last rib and the first lumbar transverse process. The udder is apparently normal. I tested the animal with tuberculin, and a good reaction followed.

Post-mortem appearances. The udder and its lymphatic glands appear normal, and also the pharyngeal glands. Both lungs are extensively diseased. The bronchial and mediastinal glands are much enlarged and caseous. The visceral and parietal pleurae, the visceral and parietal peritoneum and the omentum are all more or less covered with tuberculous proliferations. The heart presents a beautiful specimen of tuberculous pericarditis (a section of which I have brought with me). The liver and spleen are covered with tubercles externally, but their substances are normal. The mesenteric glands are much enlarged, and one horn of the uterus is slightly tuberculous.

Case 16. Cow in milk.

Symptoms. Emaciated, coughs frequently, crepitation in both lungs, the udder is apparently normal, temperature normal, her bowels are relaxed, and I found a few acid-fast bacilli in smears prepared from her faeces. I applied the tuberculin test, and at the 16th hour the temperature had risen to 104.6°.

Post-mortem appearances. Both lungs and their glands are diseased, and there is adhesion of the left lung to the ribs. The liver also contains tubercles.

Case 17. Cow in milk, six or seven years old, calved five weeks ago.

Symptoms. She is emaciated and coughs; her appetite is diminished; the respiratory murmur is increased, but no crepitation is detected; temperature 103 deg. The right front quarter of the udder is very large and is painful; its secretion is changed in appearance. A microscopical examination failed to detect any acid-fast bacilli in the smears which I obtained from it. At the time I tested the animal I found her temperature was 103.6 deg., so I applied the double test. At the 16th hour her temperature was 105.2 deg. and an ophthalmic reaction was present.

Post-mortem Appearances. Both lungs are much diseased and contain scattered foci of small purulent collections. The bronchial and mediastinal glands are diseased and caseous. The liver and one kidney show a few minute tubercles on their surfaces. The mesenteric glands are much enlarged and caseous. Both horns of the uterus are tuberculous to an unequal extent and contain muco-purulent material.

Case 18. Cow not in milk; calved seven months ago.

Symptoms. Body emaciated; temperature 105 deg.; respiration accelerated and accompanied with cooing sounds in both lungs; frequent cough and bad appetite. Her udder appears normal. She is said to have been unthrifty for several months and has wasted rapidly in the last few weeks. At the time I tested her the temperature was still 105 deg., so I applied the double test and a moderate ophthalmic reaction followed.

Post-mortem Appearances. Both lungs are affected with miliary tuberculosis and contain small abscesses. The pleura is covered with tuberculous growths. Some of the lobes of the lungs are connected by adhesions. The bronchial and mediastinal glands are much enlarged and caseous. The lungs weigh 43lbs. The hepatic glands are slightly tuberculous. The liver and spleen are normal. Both kidneys contain good sized tubercles in the bases of many of their lobules (a specimen of which I show you). The mesenteric glands are

enlarged and caseous. The uterus is normal. The udder and its lymphatic glands appear normal.

Case 20. Cow not in milk, six years old.

Symptoms. I found the animal down and unable to rise: body extremely emaciated; cough frequent, appetite bad. I tested her but no reaction followed. The owner slaughtered her himself and I had no opportunity of making a post-mortem examination, but a portion of lung and the uterus were reserved for my inspection. The lung showed the disease in an advanced stage and both horns of the womb were also in an advanced stage of tuberculosis.

Case 21. Cow in milk, five years old.

Symptoms. Body emaciated; udder normal; she coughs frequently, her respiration is accelerated and auscultation reveals crepitation in both lungs, faeces normal. An enlarged lymphatic gland is felt close to right first rib. Temperature 102 deg. She calved in June and was stocked in July. I tested her with tuberculin and her temperature rose 3.5 deg.

Post-mortem Examination. The lungs and the bronchial and mediastinal glands are extensively diseased and caseous, and together weigh 34lbs. The bronchial and mediastinal glands alone weigh 9lbs., and are some of the largest which I have seen although she is a small cow of the Jersey breed. The mediastinal gland is eight or nine inches long. The anterior lobes of the lungs are very heavy and in a state of miliary tuberculosis and the rest of the lung tissue contains caseous masses throughout, which vary in size up to three inches in diameter. The hepatic glands are enlarged and small tubercles are present on the surface of the liver. The other organs appear to be free from tuberculosis. The right prepectoral lymphatic gland is caseous and the size of a pigeon's egg. The uterus contains a foetus about four months old.

Case 23. Cow in milk about five years old.

Symptoms. Emaciation, coughs, crepitation in both lungs; temperature 105°. The udder is apparently healthy, appetite diminished, faeces normal.

I applied the double tuberculin test, and at the 12th hour her temperature had risen to 107.2°, and there was a double bead of muco-pus in the inner canthus of the eye and tears had run down the face.

Post-mortem examination. Both lungs are extensively tuberculous, and the pleura is thickened. The bronchial and mediastinal glands are enlarged and caseous. The right prepectoral gland is enlarged and caseous and it could be felt during life. The mesenteric glands are much enlarged and caseous. The kidneys are normal. The spleen shows some tuberculous growths on its surface. The liver is not tuberculous, but it shows evidence of fluke disease. The womb is tuberculous in both horns. One of the supramammary glands shows slight evidence of caseation.

In this, and in most cases of uterine tuberculosis, I have noticed during the animal's life a sticky mucous discharge adhering to the under surface of the tail opposite the labia, which had escaped from the womb.

Case 24. Cow in milk, about seven years old.

Symptoms. The posterior quarters of the udder are moderately indurated in their upper parts, especially the right one, and the supramammary lymphatic glands are enlarged. The milk obtained from the diseased quarters is quite normal in appearance, but on microscopic examinations of samples which I took, I found acid-fast bacilli in the smears. The cow's temperature is normal, she feeds well, faeces normal. I did not hear her cough, and no evidence of lung trouble could be detected. A few days after my first inspection of the animal, I served the owner with a notice of intended slaughter certifying that she was suffering from tuberculosis of the udder, and after valuation she was destroyed.

Post-mortem examination. I found the udder in the condition already described. Its weight is 28lbs. The supramammary glands are much enlarged, but are not caseous, the right one weighs 9½ ounces. The liver is enlarged and a great number of tubercles are present in its upper and lower lobes both on its surface and in its substance, and its lymphatic glands are enlarged. The bronchial glands are much enlarged and caseous, the mediastinal gland is ten inches long and is cystic. These glands weigh 4lbs. I could not find any tubercles in the lungs, they look exceptionally healthy, and only weigh 8 lbs. without the glands. One of the mesenteric glands is as large as my fist and is caseous. The spleen, kidneys, uterus, and pharyngeal glands are normal.

In nearly all the foregoing post-mortem examinations I have found the lungs and the bronchial and mediastinal lymphatic glands to be diseased. I have found the mesenteric glands diseased in nine cases. The liver was diseased in seven cases, and the kidneys in six. The pericardium and heart in one case. The spleen was seldom found to have any tubercles on its surface or in its substance. I have been surprised at the frequency with which I have found the womb to be affected with tuberculosis, and I consider that it is interesting from a diagnostic point of view. In neither of the cases of mammary tuberculosis would the owners have the tuberculin test applied, nor was it necessary. The lymphatic glands of the liver were often found to be diseased, but the pharyngeal glands in two cases only.

CASES WHICH WERE NOT TUBERCULOSIS.

Case 1. A yearling heifer, suspected to be suffering from tuberculosis with emaciation.

I applied the tuberculin test, but no reaction followed, so the detention notice was withdrawn.

Case 6. Cow in milk, suspected of suffering from tuberculosis with emaciation, and also disease of the udder.

Symptoms. Slight cough, temperature 102.4°, right half of the udder indurated, appetite bad. I obtained a sample of the milk from the diseased quarters and made a microscopical examination for the detection of acid-fast organisms, but none were found. I injected a dose of tuberculin subcutaneously, and instilled a dose of eye tuberculin into the left eye. No reaction followed the double test, so I withdrew the detention notice which I had served. The owner subsequently, on my advice, had the animal slaughtered, and the following were the post-mortem appearances: On removing the abdominal viscera an abscess burst and gave exit to a quantity of putrid, dark coloured pus, which was found to have been contained in the spleen, and it communicated with a fistula in the reticulum. I searched for a foreign body, but none was found. The spleen also contained several small abscesses, as also did the liver and the lungs, and I am of opinion that these were of metastatic origin. I prepared some smears by the Ziehl-Neelsen method, but could find no acid-fast organisms. I also stained other smears with methylene blue solution and found necrosis bacilli in abundance.

Case 8. Cow in milk, suspected of suffering from tuberculosis of the udder.

I made a microscopic examination of some carefully prepared smears, but could find no acid-fast bacilli, so the detention notice was withdrawn.

Case 9. Accidentally omitted.

Case 10. Yearling shorthorn heifer, suspected of suffering from tuberculosis with emaciation.

Symptoms. Emaciation, dulness, loss of appetite, suspension of rumination, no cough, respiration and temperature normal. I applied the tuberculin test and

no reaction followed, consequently the detention notice was withdrawn.

With good nursing the heifer eventually recovered and regained flesh.

Case 12. Cow in milk, suspected of suffering from tuberculosis with emaciation.

Symptoms. She is much emaciated, her coat is dull and erect, appetite variable, diarrhoea was also present. Temperature normal. I obtained a sample of her faeces and found a few acid-fast bacilli in the smears which I examined. I applied the tuberculin test but no reaction followed, so I withdrew the detention notice. Subsequently I tested her for Johne's disease with avian tuberculin which was kindly supplied to me by Sir John M'Fadyean, and a slight reaction ensued. This cow was eventually slaughtered, and I made a post-mortem examination, which confirmed the diagnosis of Johne's disease. The mesenteric lymphatic glands were slightly enlarged and juicy, and the small intestine showed characteristic thickening and corrugations. I prepared smears from a mesenteric gland and also from scrapings of the intestinal mucous membrane, and immense numbers of acid-fast bacilli were present, both singly and in groups.

Cases 18. Two cows suffering with chronic disease of the udder. I obtained samples of milk and made microscopic examinations for the detection of acid-fast bacilli, but none were found. A large number of streptococci was present in each sample of milk. The detention notices were withdrawn.

Case 22. This animal reacted to the tuberculin test, but was not considered sufficiently emaciated to be slaughtered under the Order.

DISCUSSION.

The PRESIDENT said on behalf of the meeting he wished to thank Mr. Caudwell for the very kind thought shown in getting up that paper and recording clinical cases which went to prove that there was hardly any part of the body that was not affected with the disease. That was exemplified in the cattle markets in London, which those who attended the post-graduate course had an opportunity of studying. There were one or two things he would like them to discuss. He would like to ask Mr. Caudwell, who had mentioned uterine tuberculosis, whether in his opinion, or whether in the opinion of any member of the Association present, it was hereditary and was conveyed from cow to calf. In the second place he would like to hear from him as to the reliability of the tuberculin test. He himself had no doubt about its absolute reliability, but he did not know whether Mr. Caudwell had had any case in which the reliability of the tuberculin test had been called into question. Then as to oestrus in tuberculous cows. It was a peculiar fact recognised by the medical profession that oestrus was greater in the human female that was tuberculous or consumptive. He begged to thank Mr. Caudwell for his paper and for the record of the cases he had given.

Mr. TOOPE said there was just one matter he would like to allude to—the question of the premature abortion of tuberculous cattle. He believed Mr. Caudwell had struck the right nail on the head. He (Mr. Toope) believed a great many cases put down to accidental causes were due to tuberculosis affecting the uterine system. He got the impression in his head many years ago that that was so; but within the last five years he had had the opportunity of examining cows that had aborted, and in one or two cases had aborted more than once—and in one case three times. These animals were suffering from tuberculosis of the womb. There were other cases of what was commonly called slinking, which he thought was also due to this, and not due to the abortion bacillus, there being no indication of con-

tagion. The frequency of tuberculous disease of the womb and ovary in these cases being very noticeable after slaughter. In the examination of the mammary gland for the tubercle bacilli, he did not think it was so difficult if they could diagnose the character of the induration of the udder. They might miss the bacillus on the first micro-examination of the secretion, but if persisted in they would get it eventually. He had never failed in a single case to get it. He had brought with him a most interesting specimen of tubercle bacilli from a cow which he had known since its birth. The cow five months ago showed slight induration and swelling in one quarter. He examined the milk and found no bacilli. He subsequently examined the milk again and found sufficient to persuade him that undoubtedly it was a tuberculous udder. She was a good cow, but he persuaded the owner to cease milking her and to report the case to the county. The owner said "No, I will not report it to the county, but will do as you suggest about the milk." She was kept and sent to the market, and an offer of £14 was made for her. The owner did not take it, and a week or ten days after he called to see the cow again, when he found her off her food. He examined the udder, which was larger than before and exceedingly hard and had no milk whatever, but in one quarter pure serum. He centrifuged this, and he found what he thought he could say was nothing less than an almost pure culture of bacilli, afterwards he found it possible to get it without centrifuging; there was no difficulty, and he believed his friend Mr. Buxton would bear him out that it was one of the richest specimens of tuberculous secretions he had examined. It was far and away richer than he (Mr. Toope) had ever examined. He wished to thank Mr. Caudwell for his interesting report of cases, which he hoped would give rise to discussion, but if not it was bound to give rise to considerable thought among them.

Mr. MORRIS said he would like to ask one question that had puzzled him for a long time. He had a cow that went up to 103° F., and he had had several go up to 103.2-5ths, the mean temperature being 100.4-5ths at night and 101° in the morning. These cows were all killed and were found to have a focus of infection. He would like to ask the meeting if anyone had found old tuberculosis surrounded by dense tissue, or, in other words, encapsuled.

Mr. HIBBARD asked Mr. Caudwell whether he considered that these cows with uterine lesions might be affected through transmission from the bull.

Mr. H. P. HOBGEN said he sent a cow from his market for tuberculosis of the udder. He only got a slight reaction, yet it was a very badly affected udder, but the cow had not had the bull at all. He did not think it followed that they could always rely on the test.

Prof. WOOLDRIDGE expressed his quota of thanks to Mr. Caudwell for the paper he had brought before the meeting, and thanked him particularly for the lucid way he had reported the cases and the results of his examinations. He (Prof. Wooldridge) thought at the present time the veterinary inspectors had a chance which had never been held out to them before to assist in the pathological problems connected with the diseases of cattle, and when reporting cases they would do well to follow Mr. Caudwell's example and refer to those cases that did not prove to be tuberculosis, so that from that data they could draw very valuable conclusions later. As Mr. Caudwell read through his cases, one or two points struck him particularly. Hitherto he had had some notion that the right hind-quarter was most frequently implicated. The notion was hazy that he had gathered, but on looking through the cases reported by Mr. Caudwell the same points seemed to crop up, and without getting down to exact cases he noticed in some instances it was the right hind-quarter alone affected, in other cases it was the right half affected, and in others

both were affected, but the right hind-quarter was most frequently mentioned. He would like to know if others had had the same experience. Mr. Caudwell raised a question regarding œstrum. Mr. Caudwell did not regard tuberculous infection as a common cause of recurring œstrum, but he (Prof. Wooldridge) did not agree with Mr. Caudwell. Any stimulation of the genital apparatus might cause reflex action and functional derangement, and oft recurring œstrum. He did not suggest that was the only cause of recurring œstrum, but thought that it was a common cause. On that same point he (Prof. Wooldridge) thought Mr. Toope misunderstood Mr. Caudwell. He did not think Mr. Caudwell suggested that tuberculosis was the cause of the abortion that often occurred. Mr. Toope certainly thought it was, and he agreed with Mr. Toope. Undoubtedly abortion did occur, and recurring œstrum was the origin of that form of abortion.

There was one other point of some importance. He noticed particularly in case No. 20 referred to by Mr. Caudwell, a case which failed to react, and on a post-mortem showed extensive uterine lesions. That answered the point raised by the President, and he would like to agree with the President that it was absolutely infallible—at any rate he thought it was almost infallible, for when they got a cow, or cattle, that failed to react to tuberculin, she might be in the advanced stage. He thought they must recognise that at once, and as inspectors they must realise it—although there had been a failure. He did not think they should dream of applying the tuberculin test to all and sundry cases they suspected. Where symptoms were clear to clinically diagnose tuberculosis they should have sufficient confidence in their ability to diagnose without testing. Then he would like to ask Mr. Caudwell in the case of John's disease what the material was with which he tested.

Mr. CAUDWELL: Avian tuberculin.

Prof. WOOLDRIDGE said avian tuberculin as pointed out was of great service in John's disease, but was by no means consistent. He thought they could say the same thing for any test for John's disease, except the finding of the organism causing it.

Mr. CAUDWELL said something had been said about the failure of tuberculin to react. He had heard nothing said about the ophthalmic test in cases tested where the temperature previously was above the normal. He had hoped they would have heard something about the ophthalmic test in such cases.

Prof. WOOLDRIDGE agreed with Mr. Caudwell it ought to be applied much more frequently than it was. As far as comparing it with the subcutaneous method it was not so reliable, but where cattle were extensively affected one might get the ophthalmic reaction. In other cases where they had got the reaction to subcutaneous test they failed to get the ophthalmic. The best thing to do was to combine the two, and so leave the least margin of error. In cattle it was a reliable test. He found the same applied for other patients, for instance, the wild animals at the Zoo. In the case of monkeys it was somewhat difficult. The ophthalmic test had been applied, but it was not easy in those cases to verify the truth of the whole of the tests. Where there had been no reaction animals had been liberated in the Gardens, and in some cases exposed to infection, and it was difficult to follow them. In those cases where they had had positive reaction it had justified slaughter, but in other cases where there had been no reaction they had almost invariably been found free from tuberculosis. He said almost invariably. Recently he came across three or four cases that failed to react to the ophthalmic test, and yet were affected severely with tuberculosis. In the horse he used the ophthalmic test in conjunction with the subcutaneous, and did not get such good results. As far as the horse was con-

cerned, when testing with tuberculin he used 8 c.c., which was twice the usual dose applied to cattle. In some cases a larger dose still was advisable in the horse, and if there was no tuberculosis there was no harm, while if there was tuberculosis they were far more likely to get reaction.

Mr. GULLIFORD said he was called in by the police to a dairy of cows and found one he strongly suspected. He continued his examination and found two more. He got well marked reaction in all three cows. All the cows were slaughtered, and in two of them there was extensive tuberculosis, but in the third one there was no trace of the disease. Something had been said about the incubative stage. He would like to know whether it were possible to get reaction while the disease was in the incubative stage and when the animal was killed to find no disease. There was a watery appearance in the milk in that case in a portion of the udder. When the udder was examined, he found no signs of tuberculosis and the hardness seemed almost to disappear. He took samples and sent to the medical officer of health at Maidstone, and he reported that all the samples contained tubercle bacilli. It was more on that report than his (Mr. Gulliford's) that the cows were killed. In the case of the third cow the injection of the guinea-pig was still being carried out. It was rather annoying to him that on post-mortem there was no sign of the disease that could be detected by the naked eye examination.

Mr. CAUDWELL said he was very well pleased with the discussion. It was a great expression of confidence as to the tuberculin test, and he believed everyone present was a believer in its almost infallibility. When they tested an animal with a temperature above the normal they could not be satisfied without a subsequent injection. That was why he advocated the double test. He was sorry Mr. Gulliford was disappointed with the cases, in which two were all right and the third failed. He found no lesions after reaction, but he was afraid it was due to Mr. Gulliford's insufficient examination. He had no doubt that there was some slight lesions that he overlooked. Mr. Dixson asked whether the disease was hereditary. He thought generally they could not regard it as hereditary. If it was, it was so in very few cases. He thought that possibly there might be an hereditary tendency. He thought it was hardly ever congenital, but it was possible that calves born of tuberculous parents offered greater susceptibility to disease than the progeny of sound parents, but that was open to question, he supposed. With regard to Mr. Toope's question upon abortion, he believed the frequent appearance of œstrum was due to abortion, and not directly to tubercular disease. Whether it was ever transferred to the bull, he thought the genital organs were very seldom affected: he did not think the bull was often responsible for transferring it to the female. With regard to Professor Wooldridge's suggestion that the right hind quarter of the mammary gland was most frequently diseased, he had not had sufficient experience to answer that question, but he could not understand why one quarter should be affected more than another with tubercular disease. As to reaction at 103°, the temperature of animals often went up to 103° naturally, but this instance quoted he thought was a case in the advanced stage of the disease, which failed to react. He should apply the ophthalmic test, and in all probability a reaction would be obtained.

Mr. GULLIFORD asked what period there should be between the tuberculin test and the ophthalmic test.

Mr. CAUDWELL said he applied them simultaneously. A vote of thanks to Mr. Caudwell followed.

THEO. C. TOOPE, Hon. Sec.

NORTH MIDLAND VETERINARY ASSOCIATION

[NATIONAL V.M.A. NORTHERN BRANCH.]

The quarterly meeting was held at the Grand Hotel, Sheffield, on Tuesday, January 20th, 1914, at 5 p.m.

Present: Messrs. F. L. Somerset (in the Chair), J. S. Lloyd, S. E. Sampson, W. Collinson, W. Brown, T. Bowett, G. J. Furness, H. Thomson, W. Murgatroyd, A. D. Morgan, T. C. Fletcher, M. Robinson, C. Secker Smith, G. Green, E. Marrison, H. P. Lewis, H. R. Laycock, and H. W. Dawes; visitor, Mr. G. Blundell.

It was proposed by Mr. Collinson, seconded by Mr. Sampson, that the minutes of the last quarterly meeting as already published be taken as read.

The HON. SECRETARY then read the report of the Council Meeting held January 13th, 1914, when it was proposed by Mr. Thomson, seconded by Mr. Bowett, that the same be confirmed.

Arising out of the report of the Council Meeting it was mentioned that the Association were now affiliated with the Northern Branch of the National Veterinary Medical Association, and that the affiliation fees for 25 full members had been paid to Prof. Wooldridge, the treasurer. The President reported that in consequence of this it was necessary to appoint two representatives to the Council of the National Association, when it was proposed by Mr. Brown, seconded by Mr. Furness, that the President and the Hon. Secretary be appointed.

THE HUNTING MEMORIAL FUND.

The HON. SECRETARY read a letter which he had received from Prof. Macqueen and Mr. H. Gray with regard to the Hunting Memorial Fund.

The PRESIDENT said "I think this Association should do all that other Veterinary Associations are doing. Personally, I knew very little of William Hunting. I knew a little of him through his writings. No doubt some of you had the benefit of his acquaintance, but I think we shall all agree that the profession has sustained a severe loss by his decease. There is not the slightest doubt that he spent a good deal of his time and money for the benefit of the profession of which he was so great an ornament. I propose that a vote of condolence be sent to his family expressing our deep sympathy with them in their bereavement."

This was seconded by Mr. Fletcher, and carried by all present rising in their places.

The PRESIDENT explained that according to Rule 11 the available funds of the Association would not allow them to contribute at present towards the memorial.

The HON. SECRETARY suggested that the consideration of the matter be postponed for some months, because at the present time the veterinary profession are subscribing to the International Veterinary Association Fund, and it is quite recognised that nothing will be finally determined in connection with the Hunting Fund this year. He said "No doubt some of the members have already subscribed, as I intend to do myself. If anyone would like to send their subscriptions through myself or the Hon. Treasurer we shall be pleased to forward it." The Hon. Secretary suggested that the matter be left over for three months, and this suggestion was agreed to.

Mr. Lloyd nominated, and Mr. Fletcher seconded, Mr. WADSWORTH, veterinary surgeon to the Great Central Railway Co., for election as a member of the North Midland Veterinary Association. Mr. Lloyd reported that Mr. Wadsworth had been invited to attend the Meeting, but had written regretting that he was unable to be present.

Apologies for absence had been received from Messrs. E. G. Johnson and J. H. Gillespie.

Messrs. H. W. DAWES, J. A. HODGMAN and G. HOWE were unanimously elected members of the Association.

ANNUAL REPORT, 1913.

In connection with the formation of the Association, thirty-two members of the profession at first agreed to become original members, but, later, three of the gentlemen withdrew, two owing to their having left the district, and one through inability to attend the meetings owing to the day of the week fixed upon clashing with a previous permanent weekly engagement.

Two additional members were elected, making a total for the year 1913 of thirty-one.

Twenty-five members paid their entry fee and first subscription during the year, leaving six in arrear. Three of the latter have since paid.

Three other gentlemen have been nominated, and will come up for election at the first meeting in 1914.

SYLLABUS FOR 1914.

JANUARY MEETING. Address by the President. Paper on "Colic—Its treatment," by W. Brown, M.R.C.V.S., Worksop.

APRIL MEETING. Paper on "Veterinary Inspection in relation to Public Health," by J. W. Brittlebank, M.R.C.V.S., D.V.S.M., Health Department, Manchester.

JULY MEETING. Demonstration on "The Lymphatic System in the Ox and Pig," by J. S. Lloyd, F.R.C.V.S., D.V.S.M., Chief Veterinary Inspector. Town Hall, Sheffield. An exhibition of humane slaughtering of animals will probably also be arranged.

OCTOBER MEETING. A paper entitled "Some remarks concerning Entozoa of the Horse," by A. W. Noël Pillers, F.R.C.V.S., Veterinary Department, Municipal Buildings, Liverpool.

The HON. TREASURER reported on the balance sheet for the year 1913, the balance in the bank being £19 2s. 8d.

Mr. FLETCHER proposed, and Mr. Furness seconded, that the balance sheet up to Dec. 31st, 1913, as presented by the Hon. Treasurer, be accepted.

Milk Sterilisation by Electricity.

For the past two years experiments have been carried on in the University of Liverpool by Professors J. M. Beattie and F. C. Lewis with a view to utilising electricity in the sterilisation of milk. The results of these researches have now been published.

One hundred and twenty experiments on a continuous stream of milk were made, and the invariable result was complete destruction of all colon and allied bacilli, and an enormous reduction in the total number of bacteria of all kinds. To the comparatively insignificant number of organisms left alive the experimenters attached no importance, and even those could have been destroyed by further treatment. Incubation experiments on large samples confirmed the Agar-plate indications, and chemical analyses by the Liverpool City Analyst proved the milk to be unaltered in constitution. The acidity of the sterilised milk remained practically constant for twenty-four hours after treatment, whereas the acidity of untreated samples rapidly rose. The taste of the milk was not altered, the fresh "bouquet" being as perfectly discernible after as before treatment, and expert dairymen could not detect the difference. Several experiments were made with milk naturally and artificially infected with tubercle bacilli, and in no case did the animals inoculated with the treated tubercular milk show the slightest sign of tuberculosis upon post-mortem examination six weeks after inoculation.

No details are published of the technique of the process, nor of its cost. The only information of this

kind given is that a high tension electrical current is used, and that the milk is exposed to the treatment for but a very short time. The experimenters say, in summing up their report, that the new system of sterilisation shows that not only can the ordinary milk-souring bacteria and bacteria of similar type, including in many cases spores also, be killed, but that, in addition, evidence has been adduced that both natural and artificial contamination with tubercle bacilli can be rendered harmless.—*The Hospital*.

Amendment of the Tuberculosis Order.

Lord Crewe, as President of the Cheshire Milk Producers' Association, occupied the chair on Monday last at an agricultural conference at Crewe. Mr. Walter Runciman, President of the Board of Agriculture, was present, and in the course of a speech said: With regard to the Tuberculosis Order, he had observed during the last eight or nine months that local authorities had practically never availed themselves of Section 20 of the Act of 1894, which allowed the local authority to sell the animals, and if the amount of money raised in salvage in that way exceeded the amount which had been allocated for compensation they would pay to the original owner the whole salvage money and not limit payment to the compensation.

Experience of the working of the order had shown that the two valuations provided did not work well, and they would have to get rid of what had been a cause of loss to a good many cow owners in England and Wales. Mr. Runciman indicated that delay in inspection and valuation would also be dealt with in an amending order, and hinted that provision might be made for a cow to be killed after 72 hours and compensation paid. In conclusion, he said the Treasury were prepared to allocate £60,000 per annum for compensation and a vote was taken for £40,000, but they had spent only £5,000, and now they must ask that the wording of the Order should be relaxed in order to come a little nearer to the Treasury anticipations of the cost.

Speaking at a dinner in the evening, Mr. Runciman referred to the healthy state of the flocks and herds in this country, and said he had been considering a scheme which he hoped to put before the Development Commission for strengthening the veterinary profession. It was absolutely necessary that greater assistance should be given from national funds to the education of veterinary surgeons, and he wished to see a profession in England on which we could rely for doing that research work in regard to animals which distinguished scientists had been doing for human beings. If those responsible for our national finance could realise how the stamping out of a single disease could add millions to our national wealth they would be more generous in the grants they gave for the conduct of the most valuable branch of the agricultural staff.

The Oldest Veterinary Surgeon in England.

In several northern papers during the past week a photograph of Mr. Henry Pulman, a registered "Existing Practitioner," of Nelson, Lancs., has been published under the above heading, accompanied by the statement that he "has received intimation from the Secretary of the Royal College of Veterinary Surgeons that he is the oldest Registered Veterinary Surgeon in the country."

On inquiry at the offices of the Royal College of Veterinary Surgeons, we learn that the statement is incorrect in two particulars: (1) That no such intimation has been sent from the College, and (2) that Mr. Henry Pulman is not the oldest Registered Veterinary Surgeon.

Successful Pony Breeding.

In *The Shetland Pony** a very interesting portion is that devoted to the Modern Pony, recounting the work in fixing a type accomplished by Lord Londonderry, with the help of Mr. Robert Brydon and the late Mr. Meiklejohn on the island of Bressay. By selection and inbreeding, the result, as the authors phrase it, was "a breed improvement without a parallel as the result of thirty years' breeding and management." The remarkable thing about this improvement was not only that it was due to one stud, but mainly to a single animal in it, viz., to old Jack (16), the sire or grandsire of almost all the stallions used. Apart from his predominance in the stud, the winnings of the Jack strain constitute a unique record in the showyard. At the last twelve shows of the Highland and Agricultural Society, since the stud was broken up in 1899, out of 116 first and second prizes awarded, no fewer than 114 were gained by the progeny of sires actually in use in the Londonderry stud—a remarkable demonstration, as the authors put it, of the influence of a single stud and a single horse upon the breed. The section on Management gives an amount of valuable information on the system to follow in order to obtain the best results, and lays emphasis on the necessity of breeders having a clear ideal in view, and an "aim independent of the changes of fashion and the varying fortunes of the showyard." The small size was fixed and exaggerated some years prior to 1845, by the crofters exporting their stoutest stallions, while, curiously enough, the scarcity of really good stallions is the chief impediment to-day to the improvement of the Shetland pony in his native home.—*North British Agriculturist*.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Jan. 23.

REGULAR FORCES. ARMY VETERINARY CORPS.

Lieut. A. B. Bowhay to be Capt. Dated Oct. 20, 1913.

Jan. 27.

SPECIAL RESERVE OF OFFICERS.
ARMY VETERINARY CORPS.

Lieut. (on probation) M. R. Lawson is confirmed in his rank.

Maj. A. G. Todd, Commandant of the Army Veterinary School, Aldershot, is to be appointed Assistant Director-General of the Army Veterinary Service.

OBITUARY

T. GIFFORD PALGRAVE, M.R.C.V.S.

Graduated, Glas : Dec., 1897.

Mr. Palgrave's death is reported from Auckland, New Zealand, on 8th December, 1913.

SIMPSON.—At Fulbrooke, Ruthin, North Wales, on Jan. 15th, Jessie Ellen, wife of T. J. Simpson, M.R.C.V.S., and daughter of Ex-Councillor Thomas Tait, of Edinburgh.

Personal.

PETTY—STEVENS.—On January 20th, at King's Road Baptist Church, Reading, by the Rev. Gordon Fairbairn, William Edward Petty, M.R.C.V.S., of Southsea, son of Benj. Petty, of Leeds and Reading, to Ellen Mary, youngest daughter of the late C. R. Stevens, of Reading, and Mrs. Stevens.

Owing to additional duties imposed in connection with the examination of cattle under the Tuberculosis Order of 1913, and the general inspection of all cattle in the City of Liverpool, the City Council have increased the salary of the Veterinary Superintendent, Mr. T. Eaton-Jones, F.R.C.V.S., from £600 to £700 with house, etc., as before. An amendment to refer the recommendation back was rejected, and the increase voted almost unanimously, more than one member testifying to the onerous and efficient work which Mr. Jones had carried out.

Mr. ALEX. DOUGLAS, M.R.C.V.S., D.V.S.M., Kilmarnock, has been appointed Veterinary Officer to the Ayr County Council. This is a new appointment, and has been rendered necessary by the increased amount of work under the Diseases of Animals Acts. There were twenty applications for the post. The salary is £300 per annum.

As a result of the accident which befell Mr. R. N. Lewis, M.R.C.V.S., Veterinary Officer to the Dumfries County Council, on August 27th, when his motor cycle collided with a motor car, his right leg has been amputated above the knee at a nursing home in Newcastle. He is now making satisfactory progress.—*Ayrshire Times*.

Mr. ARTHUR LLOYD, M.R.C.V.S., has been appointed by the City of London Corporation as an additional meat inspector at the Metropolitan Cattle Market at a salary of £150 per annum, rising to £200.

The annual retaining fee of Mr. Harry Peele, Chief Veterinary Officer under the Durham County Council has been increased from £20 to £50.

AN "INSURANCE" QUESTION.

Sir,

I should be glad of some information through your columns as to our legal liability in the case of a *locum tenens* should any such have the misfortune to meet with an accident whilst acting for us.—Yours faithfully,
Bideford, Jan. 17. Wm. Ascott.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1335.

FEBRUARY 7, 1914.

VOL. XXVI.

FOOT-AND-MOUTH DISEASE IN IRELAND.

For nearly thirty years—from 1884 to 1912—Ireland was free from foot-and-mouth disease, although throughout all that time the disease was more or less prevalent upon the Continent, from which it not very rarely spread to Great Britain. In 1912 Ireland's long period of immunity came to an end; and many outbreaks occurred in various parts of the country, some of them apparently unconnected with the initial one near Dublin. The last occurred early in November, 1912—not very much more than a year ago—and last week the disease reappeared in Kildare, which was one of the counties affected in the 1912 epidemic. These historical considerations suggest that it is possible that Ireland's increased liability to infection is due to some import which either is altogether a new one, or is becoming a more frequent one than before.

Meanwhile no further outbreaks are announced; and the prompt action of the Irish executive will almost certainly succeed in preventing the immediate spread of the disease from the one district.

THE VICTORIA VETERINARY BENEVOLENT FUND.

This Fund has recently held its quarterly meeting, at which it was announced that last year's expenditure had exceeded the income by about £20. This is a disappointment on the face of it, and becomes more so when we examine the financial details. Last year £255 was received in subscriptions, and even if all this had come from individual members it would represent only about eighteenth-pence for every member upon the Register. As some of it comes from local Societies it actually represents a still smaller sum per member. Although the profession is giving a little more to benevolence than it once did, much more must still be done before the finances of our benevolent society can be called creditable to us. The number of people who are forced to seek relief from the Victoria Fund is not very large after all, and it ought to be possible to succeed in the Secretary's aim of granting 10s. weekly in "practically every case." It would certainly be possible if comparatively a few more members realised the duty of becoming annual subscribers. There are a few objects which every M.R.C.V.S. should feel bound to support if he can—so very few that almost all of us could spare a little every year to each. The Victoria Fund is one of them.

A SECOND ATTACK OF TETANUS.

I am tempted to record this case as I have never before heard of a horse having a second attack of tetanus.

The subject is a black well-bred hunter gelding, nine years old.

I was called to see him on Dec. 31st, 1912, he had been hunted three days before. He was showing well marked symptoms of tetanus; the muscles as hard as a board, especially those of the neck; the jaws could be opened about an inch.

He was put into slings, and got a daily injection of tetanin for seven days; during this time he showed no improvement, in fact the third and fourth day he went back, refusing all nourishment, which consisted of milk and sloppy bran, with crushed oats.

On the eighth day there was a slight improvement, which was maintained, and on Jan. 17th he was taken out of slings for a few minutes, and walked round the box. This was increased daily, and on the 24th he was sent to exercise. He made an uninterrupted recovery, being afterwards hunted to the end of the season, when he was sold to another client of mine in the neighbourhood.

I could find no wound to account for the entrance of the microbe, and he had not been lame.

On Jan. 6th of this year I was again called to see him. The history was that until a week previously he had been treated by the blacksmith for a festered corn; he was hunted on Jan. 3, and was noticed to be not in his usual form. On the 5th he was hacked about six miles and arrived home very stiff, and in a white lather, was given a colic draught, and left for the night.

Again, the symptoms were unmistakable, but luckily the jaws were not quite closed, and he was able to suck nourishment. He was put into slings, and again injected with tetanin for seven days. This time I noticed no improvement until the 16th, when the jaws were distinctly more relaxed. He was taken out of slings on the 24th, for a little movement, which has been daily increased. I saw him being exercised to-day, when he moved as freely as usual, and was full of life.

In each case the horse was under ideal conditions in a roomy loose box, with darkened windows, and an attendant sleeping in the stable for the first two weeks; but although a high couraged animal the slings did not seem to irritate him in the least, and he rested in them well.

INCOMPLETE DELIVERY OF A COW.

I received a message from a farmer that he had a cow calving before her time, that the water bag had bursted four days before, and was hanging down behind, and he thought the calf must have been dead about a week.

I went prepared for a smelly operation. Some of the afterbirth was hanging from the vulva, and on inserting my hand into the vagina, I found lying there a four months foetus enclosed in the membranes. The os was almost closed, and I could scarcely insert one finger. The cow was a three-year-old shorthorn in good condition, and I cannot account for the non-delivery.

ERNEST MORGAN, M.R.C.V.S.

Faversham.

ACUTE PARENCHYMATOUS MAMMITIS
OF CATTLE.

This disease in many instances is one of the most troublesome affections veterinarians are called upon to treat, frequently resulting in undesirable sequelæ.

Its treatment by fomentations and the application of medicaments to the affected site, with or without friction, have not in my hands proved a great success, and in several instances cases have run a prolonged course, resulting in great economic loss being sustained by the owner and the value of the animal permanently reduced.

I have now discarded that treatment in favour of the application of thermofuge or antiphlogistine to the affected site, and in suitable cases employing the hyperæmic treatment of Bier in addition. The cases so treated, characterised by a condition of hyperthermia, loss of appetite, and a tense, hot and painful quarter or udder, with a flaky condition of the milk, have responded to the treatment within three to five days, resulting in the animal giving a normal flow of milk, normal both as regards quantity and quality.

The procedure is to cut out one or two thicknesses of cotton wool sufficiently large to surround the udder in which holes are made to allow the teats to hang through. A strong piece of calico is fashioned in the same manner, and enough tapes attached to keep the sling so made in position when applied.

The antiphlogistine or thermofuge is heated until it attains the desired warmth, when it is thickly smeared on the affected quarter or quarters, the cotton wool is then applied, and the sling placed in position. This is left on for twenty-four hours or longer; if considered necessary another smearing may be given.

In cattle which have pendulous udders I have found it possible to adopt Bier's hyperæmic treatment by placing at the base of the udder a broad adjustable elastic garter, after the style of the top part of a sock suspender, of such a tightness that will retard the flow of the venous blood from the udder but not interfere with the arterial circulation thereto. This bandage is allowed to remain on for six hours, when it should be removed, left off for

an equal period, and re-applied by the attendant for a shorter interval of time.

During the course of the disease I advocate withdrawing the discharge from the udder at short intervals, and administering laxatives.

R. P. JONES, M.R.C.V.S.,

Government Veterinary Surgeon,
East London, Cape Province.

HYDROCEPHALUS IN A BOVINE FŒTUS.

The following notes place on record a remarkable abnormal condition of the head of an unborn calf. The specimen was brought to me from the dairy farm at which I treated the outbreak of epizootic abortion reported in *The Veterinary Record* of October 4th, 1913.

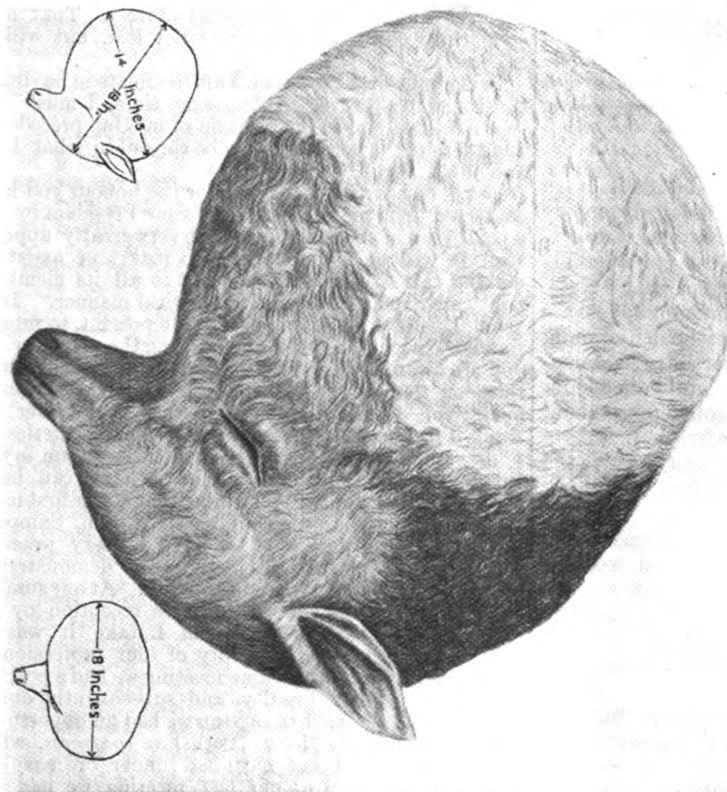

The following particulars are as complete as can be made without dissecting the head, a proceeding which would destroy its value as a specimen. The head alone was brought to me in a sack, and had an incision more than six inches long in its most prominent part, which, I am told, was a cut with a butcher's knife made to see what the head contained.

The owner of the dairy farm related that the cow was of a very common breed, and the foetus was the second calf, the first calf was healthy and was born without assistance. The cow was irrigated with the others in the treatment pursued for stamping out the outbreak of epizootic abortion, and was one of those whose genital organs admitted the full length of the pipe.

Symptoms of pregnancy were noticed about the seventh month, but after a few days they subsided, when the hair appeared to be rough, and the animal out of condition, with a faint trace of the pelvis becoming smaller. After a few weeks the cow was noticed to be very swollen in the flanks, in fact, abnormally swollen; the vulva was contracted and the anus drawn in. This puzzled the owner very much, as the cow had gone beyond her time to calve. The cow became so large that the opinion was formed that she must have twins. The animal was kept under observation in a small paddock near the house in case assistance would be required. While under observation the cow did not seem to suffer any pain, and partook of her food in the usual manner.

The owner, on going one morning to see the animal, was surprised to find her dead. Death seemed to have taken place without a struggle. He at once decided to remove the hide and cut up the carcase to ascertain the cause of the phenomenon, and then burn the remains; burning is resorted to in all cases of death on the farm as a means of preventing the spread of contagious diseases. After removing the skin, an opening was made in the flank, as that region was very much swollen, and he was surprised to find a large quantity of clear fluid in the uterus, estimated to be not less than fourteen gallons. When he opened up the flank sufficiently to see the calf, he was struck with the size of its head. It was a male, and in a

natural position. When he had taken the calf out he ran the knife across its head and found a clear fluid exactly resembling that in the uterus. The calf, with the exception of the head, appeared to be normal, and did not seem larger than one dropped at full term. This cow was cut up to facilitate its burning, the carcase of the calf being thrown upon the heap, dry wood piled on top, and the whole set fire to.

The fire had been burning for some time when the neighbour who brought me the head, came over to see the cow, and was so much interested in the strange appearance of the head of the calf, which the fire had not yet reached, that he took up an axe and severed the head from the body just behind the ears. When the farmer was asked why he did not keep the cow and the calf for me to examine, he replied, "I was disgusted with my losses, and thought that some new disease was going to break out in my farm."

The following is a description of the head, with measurements: The colour of the hair is red on the lower part and white on the upper part, and the hair is much longer and stronger than is usually seen on a calf at full term.

The shape in that portion of the head which is abnormal approaches a spheroid, the largest surface being the top. The bones in the abnormal portion appear to be one-eighth of an inch thick, and they terminate with the red-coloured hair (as indicated by the dark shading in the accompanying illustration), where they are very thin and more like carti-

lage, with an undulating edge—that is, high in the front, running up to a point, with a base 4 in. wide opposite the nose, then for 5 in. running upwards to the highest point at the sides.

There is a V-shaped cleft at the back, with a measurement of—top $5\frac{1}{2}$ in., sides $5\frac{3}{4}$ in. Diameter across the head from front to back is 12 in., and from side to side at widest part 15 in.

The following are the measurements of the stuffed specimen, as shown in the plate—from bottom of lower jaw to top of head, taken at an angle from upright position, 18 in.; from front to back, 14 in.; from side to side at widest, 18 in.

The most curious features are the forehead, with its rough, curly hair appearing to be at the back of the head, and the ears which, although they look forward, are upside down. A dissection is the only means of telling if the bones at the back which look like the forehead are really the bones of the forehead or not. The front teeth are very large for a foetus, the middle teeth measuring across the upper surface half-an-inch. The mouth is complete, with teeth, tongue, palate, and pharynx normal; the oesophagus and trachea are to be seen in a normal position. While the eyelids with long eyelashes are perfect, the eyes are rudimentary and sunk below the bottom eyelids. The measurement across the eyes from the anterior edges is 8 in. The ears large and long, measuring

$2\frac{1}{2}$ in. broad, and 4 in. long from base to tip. Measurement from tip of nose to base of ear 9 in.

On viewing the inside of the head, what comes prominently into view is the end of the spinal cord, which has the appearance of a number of fine woollen threads of irregular lengths, some 3 in. long, others not more than half-an-inch. Dura mater and pia mater intact; no trace of brain to be seen. The membrane lining the cavity is perfectly smooth, and of a dull colour.

No trace of the optic nerves can be seen; in fact, the membrane is as smooth as a dried bladder.

The specimen measures from the bottom or floor, at an angle, to the top of the undulating edge of the bones, at the highest part 16 in.; from the lowest part of the V-shaped cleft in the back part of head, 18 in. In giving these measurements it is to be noted that the back part of the head is lower than the bottom jaw.

The following measurements may serve to gauge the capacity of the head. From floor of cavity to top of head, distended, 16 in.; diameter at widest part across the head at the highest point

of the bones, 18 in. Taking the diameter at the part above-mentioned will give a fair average, as the base is smaller than the top; the top part of the head, above the bones, projects forward when it is distended with fluid and holds between 4 and 5 gallons.

J. DESMOND, V.S.

Adelaide, South Australia.

ABSTRACTS FROM FOREIGN JOURNALS

HÆMORRHAGES IN THE CARDIAC VALVES OF YOUNG CALVES.

At Rostock, in the years 1905 and 1906, a large number of calves which had died of calf-dysentery (which at that time was very violent) were examined, and in every case more or less considerable extravasations were found upon the cardiac valves.

It is now known that true hæmorrhages are present upon the cardiac valves of healthy young calves. G. Egge, of Schwaan, has been systematically working to elucidate their significance since 1905. Having charge of an abattoir where about 2500 young calves are killed annually, he has regularly examined the hearts of all, and has found extravasations upon the cardiac valves in almost all.

The extravasations appear in two forms. One consists of sharply-defined tense blood vesicles ranging from the size of a pin's head to that of a pea, from which fluid blood escapes when they are pricked. The other consists of more or less extensive superficial hæmorrhages in the tissue of the valves.

The seat of the hæmorrhages is always the free edge of the auriculo-ventricular valves, where the chordæ tendinæ are attached.

Finding nothing in veterinary literature bearing upon this condition, Egge extended his researches. He took every opportunity of examining the fœtus of cows slaughtered whilst pregnant, and also aborted calves of every age which he encountered in practice. The result was that he found these extravasations could be demonstrated in almost every case. On the other hand, the extravasations had become absorbed in calves which had died or been slaughtered after living about four or five weeks.

Finally, Egge still further extended his investigations, and examined the hearts of foals, young pigs and lambs. In these he could never find any such extravasations.

He therefore concludes that the hæmorrhages above described are *physiological* in calves *in utero* and until about three weeks after birth, and in them alone. They are absent in all other animals. The special cause of the condition is not clear to Egge.—(*Berliner Tier. Woch.*)

W. R. C.

NORTH MIDLAND VETERINARY ASSOCIATION.

[NATIONAL V.M.A. NORTHERN BRANCH.]

Continued from page 496.

PRESIDENTIAL ADDRESS.

F. L. SOMERSET, F.R.C.V.S., Chesterfield.

Gentlemen,—It was intimated to me at the last meeting of your Council that brevity was an admirable and desirable quality in a Presidential address. That hint, so tactfully conveyed to me, was not lost, but will be adhered to.

Being your first President, I am fortunate in having no traditions to observe. At the same time, I must bear in mind that I am in the position of making precedents, and therefore it behoves me to be careful in what I say and how I say it.

I wish to heartily thank you for the honour you have conferred upon me in electing me your President for the second year in succession, which I very greatly appreciate. It will be my endeavour to make, or assist in making, this Association of benefit to all its members, politically, socially, and in a practical manner. It is usual, I believe, on occasions like the present, to refer to the work which has been done during the past year. As you are aware, this Association came into being about the same time as the Tuberculosis Order also became operative. I am not going to discuss that Order. I think it has been discussed by veterinary societies *ad nauseum* during the past three months. I am saying this to illustrate the benefit that societies can be to their members. You will remember that at our first meeting, owing to the kindness of Messrs. Abson, Sampson, and Lewis, we were able to have a very practical demonstration of the best methods of demonstrating the presence of tubercle bacilli in milk. At our summer meeting we had the honour of a civic reception by the Lord Mayor of Sheffield, which I take it was an acknowledgment of the utility of our profession to the community. At the same meeting we had a polished address from Prof. Bradley, and subsequently during the drive and the visit to Buxton we had an opportunity of enjoying a talk with our Yorkshire *confères*, which perhaps we should not have had under ordinary circumstances. Then at our last meeting we had Mr. Sumner, who gave us an address on the politics of our profession, a most useful address, on a subject which may well be copied by other people.

The busy general practitioner too often displays an indifference to and ignorance of professional politics which can only be explained on the assumption that he is convinced that they are of no practical importance to him.

If the Royal College of Veterinary Surgeons obtain powers to levy a yearly contribution to their funds from every member on the Register, I have no doubt that a much keener interest in the doings of Council will be taken than is the case at the present time.

The meetings of associations such as this give to members of Council an opportunity to attend and give an account of their stewardship, to explain what has been done and what it is proposed shall be done, for the benefit and advancement of the profession and to elucidate any point which is not clear to everyone present.

I recommend every veterinary society to set aside at least one of its meetings during the year to be devoted to the consideration of professional politics, to secure the attendance of a member of Council to give an address on the subject and so enable him not only to give that information concerning the doings and proposed doings of Council to which the humblest member

of the profession is entitled, but also to sense the feelings and opinions of the profession on the political programme thus placed before them.

A mandate to proceed with or refrain from the acts proposed would thus be obtained in a far more certain and satisfactory manner than is at present possible. The only means of expressing dissatisfaction at present open to us, are by writing to the professional publications and through the ballot at elections of Council, neither of which, in my opinion, can compare with the plan suggested.

Subsequent to the discussion at the meeting referred to last, two most interesting specimens were exhibited by Messrs. Samson and Green, and I ask that every member who meets with an interesting or unusual case will go to the trouble of observing and noting down as accurately as possible the phenomena exhibited, and, of course, wherever possible, preserving any morbid specimen or microscopic slide which will serve to illustrate and explain the case. There may be men—although I can scarcely imagine it—whose only interest in their professional work is the remuneration they receive for it; I am satisfied that the majority of us take a great and genuine interest in our patients apart from any pecuniary consideration.

I have heard that some men feel a reluctance to describe cases which have puzzled them or to introduce specimens to account for which they are at a loss, because they feel it implies an ignorance of which they are ashamed. They may rest assured that the finest brains in the profession are frequently at a loss to account for phenomena which come under their notice in the practice of their professional duties.

As Professor Bradley pointed out in his address to us, it is the cocksure man, who never admits having made a mistake, who is invariably the most ignorant, and conversely those who, through knowledge and experience, have ascertained their own limitations, the more their attainments entitle them to an authoritative opinion the more modest and diffident they are in giving expression to it.

This, of course, is a phenomenon not peculiar to the veterinary profession, but is to be noticed in every phase of human activity. I have another suggestion to bring before you. It is unusual for a practitioner to call in a colleague for consultation except at the request of the client. I suggest that when he has an unusual or obscure case in hand he should, with the consent of the client, invite other practitioners to see it, not for a fee, of course, but for their information and experience, and in the hope that their combined wisdom may arrive at a solution of the problem.

Now, as to the session before us, I recommend you to consider and, if approved, adopt the suggestion I made in an earlier part of this address. That is, to set aside one of our quarterly meetings for the consideration and discussion of veterinary political matters. As the last quarterly meeting was of this nature, it would be perhaps advisable to ear-mark the last quarterly meeting of this session for that purpose, and to make arrangements with some member of Council to address us on the subject. I do not anticipate that we shall have any difficulty in filling up the syllabus for the remaining dates.

In conclusion, I hope that we shall have a full attendance of members at each meeting, that the papers read before us will prove instructive, and that they will provoke animated and informative discussions.

Again, let me remind you that reports of specimens from interesting cases are especially solicited, as are new instruments, new methods of treatment, and surgical practice; and, in short, anything and everything which is likely to prove of practical interest and assistance to your brother practitioners.

COLIC—ITS TREATMENT.

W. BROWN, M.R.C.V.S., Worksop.

Mr. Chairman and Gentlemen,—Before proceeding with the subject of my paper it is incumbent to thank you for the honour you have conferred upon me, and especially so as it is the first paper submitted by a member. I have no hesitation in asserting that the purpose of my remarks is the hope of providing a discussion from which we all may derive benefit—not that they contain anything either original or advanced.

Colic is an expression used to indicate the presence of abdominal pain, which is dependent for its production on abnormal or inordinate contraction of the visceral musculature.

Abdominal pain has various anatomical points of origin, and its exhibition varies in proportion to the intensity of the irritation in operation; it may arise from flatulence, which is due either to excessive production or diminished elimination of gas, or from abnormal bacterial activity, to the presence of irritating or indigestible food, constipation, or partial stasis of the intestinal contents, intussusception, twist or strangulation, obstruction from any cause, inflammation, ulceration, and the presence of worms. All, and each separately, produce the condition with which we are at the present moment dealing.

Colic, really, should only be used where there is neither mechanical nor inflammatory agencies operating in its production, but in practice we use the term generally, and embrace all cases of abdominal pain in the earlier stages of their appearance because, from the exhibition of the first noticeable symptoms, a period of time must elapse before we can with any degree of certainty definitely state the causes that are in operation; therefore, so far as we are concerned, we accept the term "colic," and include the lot with, however, one exception—discontinuity or rupture in any part of the gastro-intestinal system. Here the symptoms are diagnostic, and the termination is assured.

Although I intend my paper to be a practical one, I think it advisable briefly to survey the function of the gastro-intestinal system. Not only will it point out to us the method of treatment we should adopt when its environment is abnormal and inimical to the organism's preservation, but it will demonstrate to us that in spasmodic colic the abdominal pain is entirely the result of excessive neuro-muscular function.

When food enters the stomach it provides the stimulus requisite to initiate the digestive process, and as a result of which the food is pushed along the alimentary tract. In this journey it is broken up, more or less separated, and becomes fitted to be operated upon by the various glandular secretions when it reaches the anatomical positions in which they are situated.

Whilst this process is in operation, and as a direct result of it, the several chemical constituents of the food become soluble, are chemically altered, and are then suitable for absorption. This accomplished, it supplies the tissues with all that is necessary both for present and immediate future requirements.

After abstraction of all the assimilable elements contained in the food a residue remains which varies in quantity according to its original chemical constitution, and this must be eliminated in the form of excrement. This is also brought about by the same action as that required to start it, in the first instance, on its journey.

The action or movement which confers this propulsive power on the system under consideration is known as peristalsis, or peristaltic action; it is a reflex act, and depends on the following factors for its production: (1) A receptor or initiating organ; (2) a conductor; and (3)

an effector. The first is supplied by the nerve terminals situate in the visceral organs, and the second and third by the chain of neurones which convey the necessary stimulus to and from the nerve centres, the stimulus to set the operation going being, of course, the contents present in the gastro-intestinal system.

It is important to remember that the seat of pain is located in the cerebrum, and that reflex action can become operative even if this part of the cerebro-spinal system is obliterated. This is a point to remember when dealing with "pain," and has some bearing on the method to be adopted in combating it.

Reverting to peristalsis, it may be accepted that the strength of the muscular contractions produced is proportionate to the amount of irritability exerted in its production; thus food of a fibrous, bulky and coarse texture demands far more strenuous attention than does an equal bulk of soft, non-irritating food of a succulent nature, and it has seemed to me, where an animal has been suddenly turned on to a succulent spring pasture, where, as is generally the case, he has partaken of the luxury provided too freely, rapidly, and in many cases fatally, that the required stimulus to deal with this unexpected environment is not developed with sufficient rapidity, consequently fermentation or putrefaction commences in the food, an already distended stomach is still further inconvenienced, the muscular fibres of the stomach become stretched, and, finally, so abnormally are they affected that they refuse their office, and a paralytic condition of the organ follows which terminates in death. Here, then, we might assert that we have caught the alimentary function "napping," and the reason I attribute for this state of things is that the animal, having previously been fed on food which, owing to its constitution had provided a stronger stimulus, the function had, as it were, become mechanical or automatic, and could not discriminate with the celerity demanded when a different food, both chemically and physically, had been partaken of.

For the purpose of this paper it is unnecessary to more than note several gastric conditions which, probably unrecognised during life, are pointed out to us on post-mortem. Ulceration, malignant disease, acute inflammatory areas resulting from the action of chemical irritants, all come under observation usually only when death has occurred.

Apart from the irritation produced by the presence of worms in the intestinal canal and the partial stasis existing in the less severe forms of constipation, we may look upon all those cases affecting this part of the anatomy which require our attention as due to obstruction, unless, of course, it arises from that very uncommon disease, enteritis.

Obstruction is a condition produced by accumulations of undigested food, malignant disease, intussusception, twist, and strangulated bowel from any cause. It is not necessary to differentiate with minuteness these various pathological conditions. It is sufficient to state that they cause in most cases unsurmountable objects whereby they prevent the system from carrying out its necessary function. As the result of their presence irritation is set up, abnormal neuromuscular action commences, the circulation is interfered with, and intestinal glandular secretion is more or less inhibited. Unfortunately for us as practitioners, the finer methods adopted by the human attendant to aid him in his diagnosis are not at our command, therefore we must adopt a method of treatment which, whilst in ignorance of the exact conditions prevailing, will return for us the best average results.

Where an obstruction exists, it opens up many possibilities; we know that peristaltic action will strenuously attempt to gain mastery, and will continue its fight until the nerve cells tire owing to the chemical changes which occur in them as the result of the using

up of their store of oxygen; or, further, until inhibitory action initiates its function; this, as you all know, does take place, and can be proved by each of you if you will endeavour to observe evidence of peristaltic motion in an animal subjected to a condition of obstruction.

Also, we may, as the result of the continued presence of the obstruction in contiguity with the intestinal wall, get ulceration, sloughing, perforation and peritonitis, and in several cases which came under my notice at one farm some years ago, this latter condition took place when the obstruction commenced to move, and was followed by death. Again, we must recognise that our animals are vegetable feeders, and that in this class of ailment there are an enormous number of bacteria. When an obstruction exists the peristaltic action is specially energetic anterior to it, and the food is passed rapidly towards it; here it may finally become more or less liquefied, stasis follows, and thus is provided a most favourable situation for bacterial decomposition.

It is now my intention to speak of the methods I employ to deal with the situations we have observed. No doubt it will be thought rather risky, that is, some part of it, but I am of the opinion that when you are aware of the fact that an obstruction is present, the sooner you go for it the better is your chance of removing it; that is, if it is one that can be so subjected. If it is not, however, it does not really matter so far as treatment is concerned, because the earlier these incurable cases are terminated the better it is for all those connected with them.

In speaking of the agents I use in the endeavour to procure a favourable result, I am conscious of the fact that many practitioners have remedies which it would take more than average persuasion to get them to eliminate from their routine treatment. Some use general stimulants, others local or general sedatives. Personally, I use a combination of tinct. morphia and chloroform, together with turpentine. As an ordinary draught it has served me well; its combination is good, because it also possesses an antiseptic action.

Sometimes, the action we desire is not forthcoming; it may be that the medicine given does not control the local spasmodic action—it may have been altered in its chemical constitution, or cannot come in contact with the area of irritation; therefore, I administer morphia and atropine subcutaneously. This, if effective, brings the local irritation under central control, and if your case is one of spasmodic colic it usually rapidly disappears.

This desirable consummation is often delayed. Pain continues, and we are then faced with a problem which demands serious consideration, unless, of course, you are in the habit of treating similar cases in the same manner I adopt. Some practitioners would administer a physic ball or draught, then submit themselves to a condition of "masterly inactivity." Personally, I think this a very unprofitable occupation, because whilst you are waiting for this very, very slow process to operate, a favourable opportunity is granted for unfavourable work to be accomplished through agencies which have previously been enumerated.

It is several years since I commenced to use physostigmine salicylate, and if there are any members present who have declined to use it on account of the many "terminological inexactitudes," related about its action, I would ask them to follow out the methods I adopt—where its use appeals to me as absolutely necessary—and I venture to assert it will then become part of their general treatment. Physostigmine is a gastric, intestinal and hepatic stimulant—it increases peristaltic action and is, undoubtedly, the finest agent we have when there is impaction, obstruction, or paralysis of the gastro-intestinal system. But it is to be remembered that the actual cause of a removable accumulation is not always because the food was of an indiges-

tible nature, there are other causes which bring this condition about, and these entirely referable to deficient neuromuscular function which is also further complicated by the necessarily similar condition affecting the intestinal glands and their function.

This, then, is the drug to inject subcutaneously, but before doing so give, orally, a pint of warm linseed oil. If there is intestinal distension give a clyster, examine the bowels per rectum, and if you find there is a possibility of relieving the accumulation of gas, tap the bowel in this position with a small trocar or a large hypodermic needle. I advise this position, because to produce an unnecessary wound through the flank whilst an animal is in the condition under notice, is bad treatment; it produces irritation, and opens the way for septic or inflammatory conditions which, under existing circumstances, are capable of producing an amount of inhibitory action on the abdominal viscera which is unfavourable.

Having attended to the preceding instructions, inject physos. salicylate, but do not use too fine a needle, because the preparation is not quite soluble and it may plug the needle up. After this, wait for the drug to do its work. In many cases the interval is not long; I have seen expulsion of faeces in seven minutes. Usually the animal will lie down broadside, give a sigh of "suddenly realised alteration," expel gas per rectum—which it repeats in a few minutes; later it gets up, sometimes gives itself a natural shake, then there is the appearance of faeces, sometimes not much, but usually it is soft in character, and is followed at short intervals by further action and greater quantities; I cannot say, as some do, that it produces salivation. I have not observed it as one does when using arecoline—by the way, this is, in my opinion, drastic; it produces salivation of a copious nature, and I think produces pain. I have only used it three times; in two of the cases we had laminitis in forty-eight hours, the other died, and the owner, having noted the action it produced, swore that I had poisoned it. Since that time I have always used "physos." and with each succeeding year I became more and more convinced that it is the correct treatment.

I will just mention two cases with which I had to deal in November last, to demonstrate the value of the old and the more recent treatment. A client who is an agriculturist, is in the habit of giving his working animals—some in number—a bran mash every Saturday night. He carried out his usual procedure on a certain Saturday, and the next morning, about 6 o'clock, found one of the mares with "colic." He gave one of the draughts I have mentioned, and one hour afterwards gave another; these had no effect, consequently he desired my attendance. I arrived at the conclusion that the mare was suffering from obstruction of bowels, therefore administered the "physos." treatment, to which she responded, and was soon all right. On the farm there were assembled members of a "ratting club," so you can feel assured I entered into their sport.

As I was about to leave at mid-day, another animal, a valuable four-year-old colt was found with abdominal pain. A draught, enema, and finally morphia and atropine were administered, but we had no response. Owing to having acquainted the owner with the various ideas pertaining to the use of physos., he requested me not to use it, owing to the value of the colt. I allowed him to have his own way and stuck to the antiquated methods of our forefathers, which did not avail the animal much comfort or relief. Tired out, I left him about 12.30 a.m., with instructions to give a bottle of linseed gruel every hour, and also to walk him about occasionally. This, of course, is an aid to peristalsis; it varies the intra-abdominal pressure through contraction of the abdominal muscles.

Imagine my disgust when at 5 a.m. I was called out to attend the animal again. On arrival I found a state of things which irritated me very considerably. The animal was suffering severe pain, bathed in perspiration, abdomen distended, and presenting every appearance of an animal that is rapidly qualifying for a position in a cat's-meat factory. Without hesitation I at once applied the "physos." treatment, and I can assure you its effects were simply marvellous. In fifteen minutes we had one motion, in one hour we had approaching a dozen, and the animal soon became calm and contented.

Here you will see we had two animals suffering under the same conditions of work, food, and usual routine treatment, the first had "physos." early in the attack; the second at a longer interval; the first recovered, and we had no further trouble with it; the second was a source of worry for upwards of a week; he would not eat, was occasionally subject to slight abdominal irritation, his temperature and conjunctiva varied—in fact, to put it shortly, he was both unsatisfactory to himself and a source of worry to me. I gave him belladonna and sodium bicarb. for several days—one dose at each end—after which he became his usual self. Now I ascribe this sequel to having waited too long before attacking the obstruction, because I have never observed it where it has been resorted to early, and now that I have realised this, it is my intention in future both to have my own way and administer it quickly.

It will now be seen that the only drugs I employ in the treatment of abdominal pain are Tinct. morphia and chloroform, turpentine, linseed oil, and physostigmine; and I trust you will not think me presumptuous when I state that, armed with this small combination and a hypodermic syringe, I should consider myself adequately provided for all abdominal cases to which I might have to attend.

DISCUSSION.

The PRESIDENT: I think you will agree with me that this paper has taken a considerable amount of time and trouble on the part of Mr. Brown to prepare, and it now remains for us to discuss it. For my own part, I think a paper of this kind is more valuable if the reader can bring forward something definite in the matter of diagnosis. I, personally, find some difficulty in differentiating the forms of colic with which one is confronted in practice—an ordinary case of obstruction, a case of stone, a case of twist, or a case of rupture. I think I understood Mr. Brown to say there were distinct diagnostic symptoms in the case of rupture. One thing that he did not mention, and which, from experience, I find to be very necessary, is rectal examination. One goes to lots of cases of colic, and I know that in many instances, rectal examination is not made.

I had an instance the other day of its value. The pulse was very high, but there was evidently obstruction. When I tried to insert my hand in the rectum I found that about 3 inches inside beneath the rectum, between it and the bladder, there was some kind of an abnormal growth, and that was the cause of the trouble. If I had gone on with the treatment described by Mr. Brown, I do not think I should have had the success obtained by the use of the hand and subsequent warm enemata. The cause of the trouble was removed, and the animal recovered. That is merely a suggestion, and on that I think a valuable discussion on this paper can be evolved.

Mr. T. C. FLETCHER: I am sure in listening to Mr. Brown's paper we were all relieved to find that the treatment of certain diseases that we are no doubt bothered with is so simple. I am sure I am relieved because I have stayed up a good many nights and spent a good many hours in studying the various phases of

colic, many more than I shall do in future if I adopt Mr. Brown's treatment. I knew from previous speaking with him that in giving his method of treatment he was going to lay particular stress on the use of physostigmine. It is well to have a good opinion of your own treatment, because you take a firmer hold of your case than if you are not quite confident as to which particular form of treatment you should adopt for a particular form of colic. Now, to my mind, Mr. Brown has used the term colic rather widely. He classes under it cases of obstruction, stone, twist, and rupture. He even puts under the head of colic cases of intussusception. Perhaps in our ignorance in diagnosing intussusception we are prone to the use of the word colic—often suggested by the owner. By agreeing with him so far it relieves us from making a more definite diagnosis than that at present we have got a case of colic.

Colic has always been to my mind a synonymous term for a spasm of the bowel, and in all colic drinks we are trying to formulate a drug of sufficient value to relieve spasm of the bowel, and I think that is our first duty, because the diagnostic symptoms that we go on of the different diseases that Mr. Brown enumerates under the name of colic are consequent upon time and upon our observations of the animals. There is no doubt that the rectal examination of our cases is a thing that we very often shirk. I have shirked it myself in dozens of cases, but an instance occurred to me some 12 months ago that taught me that, although it was a cold day, and it is not a nice job to make a rectal examination, we must put on one side our feelings and make such an examination when in doubt.

Mr. Fletcher then cited several cases which had occurred in his practice. He discovered a case of flatulent colic, in which, by rectal examination, he found that the distended bowel filled the pelvic cavity and obstructed the rectum. By pressing the distended bowel forward for four or five minutes, gas escaped almost immediately and afforded relief.

A second was the case of a pony in which a dose of physic did not seem to have effect, and in consequence he injected a grain dose of physostigmine, but with no result except that the pain was increased. In the course of time the physic acted with very gratifying results, so he shall not feel inclined to follow the physostigmine treatment with the same vigour as Mr. Brown. He is a strong believer in exercise, which probably acts by producing debility in the animal and counteracting the depressing action on the muscles of the bowels. In support of this Mr. Fletcher gave an instance where an owner invariably sends his cases of colic a considerable distance to his infirmary, and how he had been struck by the number of cases which, on arrival at the infirmary, required no further treatment. He said that one sometimes comes across a case where the results obtained by post-mortem examination make one ashamed of oneself, of one's treatment and powers of diagnosis, and these are the cases which make it necessary for veterinary surgeons in practice to treat their clients as well as their cases.

Mr. GREEN: I must thank Mr. Brown for the very able paper which he has given us, and which has proved so very interesting, because it is a subject upon which there is a large amount of latitude, and it is a subject upon which any amount of discussion can take place. In the first place I noticed that Mr. Brown left out what is, in my opinion, a very important matter, that is, when I go to a case of an animal suffering from colic, whatever the cause, the first thing I do is to take the temperature, next I take the pulse. The character of the pulse in a case of colic must be a very essential point in the matter of treatment. If I go to a case where I have got a good pulse, where the temperature is normal, where there is little or no distention, then I

say to myself I have a favourable case. If on the other hand I go to a case where the temperature has probably risen to 103, with a considerable amount of distention, and the pulse is down, then I begin to ask myself what is the cause of this. Many cases of stoppage are not due to obstruction by food, but due probably to a chill which is affecting the nervous system and the pulse, and probably, as Mr. Brown mentioned, due to some paralysis of the muscular coat of the bowel.

For my own part I am not a believer in physostigmine. I never use it now. I have used it on many occasions. I have had cases where in the initial stage the pulse has been a good pulse, and the temperature has been practically normal. The case has not got on as satisfactorily as one would wish, and I have injected $\frac{1}{2}$ grain of physostigmine. With what result? A considerable increase in the amount of pain, and, in many cases, when I have taken the temperature again it has bounded up, the pulse has become weak and thready, and in course of time death has taken place. Now what I would like to ask is—is this the result of the action of physostigmine on the pulse, or is it the ordinary course of the case? In my opinion many a strangulated bowel is due to physostigmine.

There are one or two other points which I wish to touch upon. One is the use of colic drinks. I think the persistent use of colic drinks is a very invidious procedure. I believe that many a horse has been poisoned by the use of drugs such as opium and other sedative agents, and if you find that a couple of colic drinks do not relieve a case then I think that other measures are necessary.

My mode of treating colic is in the first place to give a colic draught. I might say that I make it up of 1 oz. tinct. opium, $\frac{1}{2}$ oz. tinct. chloroform, and 1 oz. turpentine. If that does not act, I give another in an hour perhaps, not less. If that does not act I give a physic ball, and I am not ashamed to use the old fashioned treatment. In an hour's time, if there is no relief, I administer stimulants and repeat this every three hours, and I must say I have had a considerable amount of success, in fact, I have had more success in treating colics, stoppages, etc. by this treatment than I have ever had by using physostigmine or arecoline. If they do not respond to this I tap the bowel in the old fashioned way through the side. There is just one other point I should like to mention, and that is exercise. I think it is a very cruel and a very wrong thing to cause an animal which is suffering a large amount of pain to be dragged around a field or walked about for hours. I put myself in the position of this animal. It is suffering great agony. One would not like if in pain of that description to be made to walk about for hours.

Mr. FURNESS: I am very glad to have heard Mr. Brown's paper, and I think I shall have to express myself as one who practices the old fashioned treatment. I have not had very good results from physostigmine. Different cases require different treatment. I do not see much objection to exercise in moderation, as many times you will have noticed a horse in pain will take exercise himself, so if he is conducted about a field I do not think there is very much difference. I was rather amused at the owner accusing Mr. Brown of poisoning the horse. I had a similar case some time ago. I did not like the look of the horse, and the owner said "that it would never be better if he did not have a passage," a remark with which I agreed.

Mr. BOWETT: I should like to ask Mr. Brown to say what is his method of treatment in the case of a mare heavy in foal. I do not think myself that morphia has much effect as a sedative on horses. I think chloral is much better. I also think that in cases of colic there are other things to be attended to besides stoppages. If the horse's heart is very much down I think it is

necessary to give him hypodermic injections of strychnine.

Mr. SMITH: With regard to physostigmine, I have given it a very fair trial, and I cannot say I have had any good results from it. Of course, like one or two of the previous speakers, I am not ashamed of saying that I go in for some of the old fashioned treatment. There are two things which Mr. Brown did not mention—one is counter-irritation, and the other fomentation. With regard to counter-irritation, I cannot say that I am altogether in favour of it, but in some cases that is the only thing that you can do. I place a lot more faith in fomentation, but as many of you will know, in cases of great violence it is impossible to use that course of treatment, and I have in some of these cases resorted to counter-irritation, and I must say that it has acted fairly well, but I have never been as satisfied as I have with the results obtained with fomentation.

Mr. COLLINSON: In country practices we get a lot of colic, and some years ago I was very great on using physostigmine, but had very bad results. Latterly I have used arecoline, and got better results than formerly, but I always make a point of telling the owner, provided he has not had a case before, that there will be a lot of salivation. I make a rectal examination in the majority of cases, because I think it is one of the best ways that we have of diagnosing a case. The use of the thermometer is also a good thing. One thing that has not been mentioned is massaging the abdomen. I find that if you have a horse that is subject to flatulence if you get a good hedge stake, or a good fork handle, with a man at each side to massage the abdomen, in a good many cases you get rid of a good lot of flatus in that way. As a sedative for colic I, too, use chloral, giving 1 oz. as a dose. If that does not act I give a hypodermic injection of arecoline. If you get an action by arecoline in the first instance you hear the bowels working, and if you do not get an expulsion of faeces or flatus I think it is advisable to repeat the arecoline if the horse is not in very great pain.

I had a case 12 months ago. It was a half-legged horse which used to run a grocer's dray. This horse had a stoppage for nearly three weeks, but no pain. He was treated. He had a gallon of warm oil, physic balls, and I do not know how many hypodermic injections of arecoline, and I think he had three dozen nux vomica powders. Mr. Green came in consultation, and we decided to destroy him. We made a post-mortem and found he had a partial twist of the bowel, causing an obstruction in the small bowels. He had had a good pulse all the time. He was examined per rectum several times, and there was rectal obstruction, as each time he had a hypodermic there was inflation of the bowel.

Not long ago I was fetched to a horse with colic. The rectum was dilated, and there was nearly half a barrel of manure in his rectum. As soon as this was got away I gave him an enema and six nux vomica balls. He made a satisfactory recovery. He was a hunter, and he had been sent to a farm to eat for work. He was put on to cart horse feed, a lot of chaff, and I rather thought he was not getting a sufficient quantity of water to stimulate the bowel.

Mr. SAMPSON: I have been thinking about colic today, thinking I might want to say something to Mr. Brown. In looking back as far as one can without the aid of a case book, and taking into consideration the character of the colic that one gets, I have come to the conclusion that cases of colic in towns vary considerably from those one gets in country practice. There is one difference—that is the feed. In the country the animals are fed on rough chaff and little corn, but in town you get a liberal allowance of corn and good feed. I should like Mr. Brown to give his opinion. It may account for the number of cases of volvulus in the

towns. In my opinion you get a smaller percentage of twist in the country. I have used physostigmine, and also arecoline and hydro-bromide. As to the latter you get such an abnormal amount of salivation that it does not leave a good impression on the client. I should like to have had an expression of opinion from Mr. Brown as to the horse lying down or being kept up in colic cases. One sometimes get a stubborn client who will not allow his horse to lie down. I should also like to hear if it has ever occurred to Mr. Brown to operate where it has been possible for him to diagnose mechanical obstruction.

Mr. ROBINSON: I have used arecoline, and I have used physostigmine, but I cannot say I am very much in love with either of them. Of course the main thing is choosing your case, because I have seen rupture of the bowel succeeding both of them. The best remedy is the old one of turpentine and raw linseed oil. I now never use anything else. For the first ten years in practice, however, I did use physostigmine. With reference to massage, I have had good results in many cases by putting a man at either side to rub the patient down.

I am a great believer in the hypodermic injection of morphia when there is pain, and in giving a physic ball. You must first ease the pain, and then something is wanted to move the obstruction.

Mr. THOMPSON: I am not a believer in the use of the drastic purgatives mentioned by Mr. Brown, nor should I ever use arecoline or physostigmine—for this reason. Some years ago I was in Liverpool and came across a man who was a great believer in drastic purgatives. What put me against the use of drastic purgatives was the result of post mortem examinations which showed a state of things I had never been used to seeing, and that was horses dying from inflammation of the bowels. I was there three or four weeks, and in that time I saw four or five cases of death from inflammation of the bowels. It was violent in character, and gave one the horrors to look at it. It was not the inflammation that I have found in a case of twist or anything of a passive nature, and there is not the slightest doubt that it was due to the drastic purgatives. I have used these, but only when I was compelled. Of course my father was a veterinary surgeon, and I have his advice to keep off these fast purgatives, and instead to get the bowels prepared by encouraging peristalsis and effusion into the bowel. Whereas if you use these things such as physostigmine, which Mr. Brown says moves in seven minutes, you can imagine what would happen if the stoppage was a calculus. One thing certainly troubles me with regard to colic and that is where you get the stomach blown up, regurgitation, and gas up the oesophagus, and gas in the stomach, which in many cases I find very hard to treat, and ultimately ends up with a ruptured stomach. The natural form of the stomach with its trap-like exit is one cause of the gas not being able to pass on to the smaller intestines, and then we have the difficulty with the horse that he cannot vomit or pass food. There is no doubt that if he could vomit he would relieve the stomach and would be cured. I remember seeing in one of the papers some years ago a recipe which was said to have produced good results with flatulency of the stomach.

Mr. COLLINSON: With regard to flatulency of the stomach, I should like to ask if any member has tried passing the probang. If you stand at the side of the horse you will hear rumblings at the side of the oesophagus, and if the animal is fairly quiet and the probang is well oiled it is not a difficult matter to pass it into the stomach, when the gas immediately escapes. If the animal is not quiet I put the hobbles on. Before withdrawing the probang I give an antiseptic of glycerine and carbolic acid and pour it down the probang. I have used it several times to cases which have

come round, and which formerly I should have given up.

Mr. MURGATROYD: I was called to a case one night and found a horse which, at a casual glance, you might have said was suffering from congestion of the lungs. There was rapid and shallow respiration. Perspiration was streaming from the horse. I took the temperature and found it to be almost normal. The pulse was very weak. I auscultated the lungs, but the sounds were good. The Owner said "Come away, or the horse will kill you." I came away and the horse dropped down. It would stand for half an hour or so and then fall down. I watched it for some time and noticed that it made attempts at vomiting. I went about four o'clock in the morning and it died about four hours later. I told the owner the horse had probably had a rupture of the stomach. On post-mortem I found the colon was perforated with a jagged irregular perforation. I did not know how to account for it, but came to the conclusion that it had swallowed a nail or something of the sort. It was so peculiar that I told the knacker to keep the specimen on one side in order that I might show it the owner. Mr. Lewis saw it, and took the ulcerated part home and examined it microscopically. He found it was due to the bacillus of necrosis.

REPLY.

Mr. BROWN: I must say that I am very much surprised that so few of you know the value of physostigmine. I have used 144 doses when I have finished the tube which I am at present using. I have used it for five years. Some gentlemen say that it increases pain. It does not do anything of the sort. I am speaking of the salicylate of physostigmine. It paralyses the nerve centres, and the action is on the muscular coat of the bowel. It is not a drastic purgative. It acts through the muscular coat, causing contraction and increased glandular secretion. I always administer a pint of warm linseed oil, for this reason—it is a lubricant, and it is a gastro-intestinal stimulant. When it comes in contact with the bile it forms soaps, and so lubricates the intestine. I think, therefore, the reason of failure is that the lubricant has not been given, and I am very much surprised to hear the gentlemen say they have had bad results. Some gentlemen spoke of morphia and atropine; these act upon the higher centres and dull them, and all nerve cells which come in contact with them, and puts them in the same condition, contrary to physostigmine.

Mr. SAMPSON asks about lying down. Twenty years ago I was with a man who never allowed his patient to lie down. He used to put them in a stock. My candid opinion is this, if you have a horse with distention he refuses to lie down. The more distended he becomes the less he tries to lie down. We talk about the stomach of a horse. It is the most delicate organ in any animal. Suppose you get a horse feeding under different conditions, first on a dry fibrous food and then a succulent food. You know as well as I do that if he is turned out into fresh pasture he will over-eat himself. You know, too, that if a change in feeding is done slowly no harm is done. You can get a stomach used to anything, but if you change a horse's food suddenly in its substance and bulk you are asking for trouble.

With regard to operation, I say No. It does not need any further remarks. You gentlemen have all seen a post-mortem, you have all made them, and I think he would be a very bold man to operate. My opinion is that a twist occurs at first, and I think the loading, and the straining that is necessary to start loads off, is responsible. If you get a twist the horse starts with pain and his pulse gradually runs down. It is a spasmodic contraction originally, and is often due to an attack of pre-existing colic.

If you have a rupture of any size, my opinion is that your animal is as a rule in a cold sweat. If you get an animal in that condition—collapse, cold sweat, cringing—it is my opinion you have a case of rupture.

Mr. Fletcher said that according to my paper the treatment of colic is simple. It is, in my opinion. If you have a case of ordinary spasmodic colic you give the patient a colic drink, and if it is spasmodic colic you may not hit the spot directly, but if you will give him after that a hypodermic injection of morphia and atropine you hit the spot. I do not believe in fomentation. Mr. Fletcher does not believe in physostigmine, and he does not believe in arecoline. I do not believe in arecoline. I have been trying to point out to you that the cause of trouble in these cases is delay. You know in these cases that something has to be moved, and surely the sooner it is moved the better.

I do not attach any importance to the temperature in colic. I do not think there is the slightest indication to guide you as to what the case is to be. You get many a horse with a temperature of 102° to 104° which recovers.

Some years ago I had a series of cases—I think Mr. Bowett will remember them—of obstruction. We did not know the use of physostigmine in those days, and the horse I am thinking of went on several days. As the days went on the pain did not increase. He began to distend and finally died. On post-mortem everything was found to be liquefied in the intestinal canal, and yet there was never any passage. He died of auto-intoxication, and I maintain that if he had had a dose of physostigmine he would not have died.

With regard to colic drinks—we are professional men and we all know the value of medicine. You know as well as I do that there are many cases of spasmodic colic which get better on their own. In such cases it is immaterial what colic drink you give as long as you give them something.

Mr. Green mentioned exercise. You will walk an animal about, and he will be fairly easy, put him in a box and down he goes. Exercise is undoubtedly a fine thing to adopt in a case of obstruction, because it is a stimulant to peristalsis.

Mr. Bowett asked what about a mare in foal. This is a very difficult problem, and I may as well tell you I gave a mare in foal a dose two nights ago and she recovered. I once had a mare and she had three attacks of colic—one before Christmas and two after. She had a dose the first time and the second time. Later, three weeks before foaling, she had a stoppage, and was in a stall lying on her back, and had to be dragged out. I gave her a dose of physostigmine and she had a live foal.

In conclusion, I wish to thank you very much indeed for the way you have listened to my paper. In using physostigmine do not wait too long, do not forget your linseed oil, and if at the finish you find a twisted bowel, do not suppose the physostigmine was responsible, because the twist was there before.

Mr. LLOYD proposed, and Mr. Murgatroyd seconded, that a hearty vote of thanks be given to Mr. Brown for his very able and interesting paper. Mr. Lloyd said that no doubt when the paper was printed in the veterinary press it would cause some comment and discussion, and he hoped that when the discussion did start it would be to Mr. Brown's credit that he had started it.

The members then adjourned for tea.

SPECIMENS.

Mr. BROWN exhibited the fore feet of a pig which he had seen exposed for sale in the market, each foot being practically double. He also exhibited a portion of

the intestine of a horse which had been gradually but completely occluded by the growth of a tumour. He stated that the latter had been examined by Sir John M'Fadyean, who had informed him that the tumour was an adenoma.

Mr. SAMPSON exhibited a dog which had an abnormal growth or thickening in the skin on the side of the neck. He stated that the animal had been under treatment for some time and that the affected part had considerably improved. The owner, however, did not wish to keep the dog longer and intended having him destroyed. He did not know the cause or the nature of the growth.

Mr. Sampson also showed the foot of a four-year-old half-legged mare. The history of the case was that one leg had slipped into a hole, after which the animal was found to be lame. The lameness passed off in four days and the animal worked two days, when the lameness reappeared in a very acute form, and an abscess formed on either side of the coronet. Owing to the fact that there was at first some pain and swelling at the heel, Mr. Sampson thought the cause of the lameness might be fracture of the navicular bone. Mr. Abson, who later saw the animal in consultation, and after the formation of the abscess, thought that probably the wing of the Os pedis was fractured. The animal was slaughtered three weeks after the accident, and post-mortem revealed a longitudinal fracture of the navicular bone, with slight erosion of the corono pedal articulation.

Mr. THOMPSON exhibited a hatpin, 12 in. long, which he had successfully removed from the interior of a Scottish terrier puppy, the pin being nearly as long as the dog. The point of the pin could be felt in the pharynx. It was forced through the skin and extracted until its further passage was obstructed by the head. Mr. Thompson then reversed the direction so that the head could be pushed backwards from the pharynx through the mouth, and so successfully removed it. The dog made an uneventful recovery, and was subsequently sold for £15.

Mr. H. P. LEWIS exhibited a remarkable specimen of tuberculosis of the uterus of a cow. Owing to tuberculous deposit the wall was $\frac{3}{4}$ in. thick, the one horn being much more diseased than the other.

He also exhibited the intestine of the horse mentioned by Mr. Murgatroyd in the discussion on Mr. Brown's paper. This, as already mentioned, was caused by the bacillus of necrosis, the specimen showing well-marked ulceration with perforation.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A. NORTHERN BRANCH.]

A Meeting was held on December 19, 1913. There were present: Messrs. J. P. Heyes (President), E. J. Burndred, H. Holroyd, H. G. Hewetson, A. B. Mattinson, F. A. Ball, W. J. Fletcher, T. Dobie, J. W. Brittlebank, J. Sumner, J. T. Share-Jones, A. Walker. Visitors: W. J. Young, C. Holland, A. M. Munro, and J. S. Lloyd.

On the motion of Mr. SUMNER, seconded by Mr. Hewetson, the minutes of the last quarterly meeting were confirmed.

The HON. SECRETARY read a letter of apology from Mr. Henry Sumner, who was unable to attend.

A letter was also read from Mr. Frank Garnett, asking

for a donation to the International Veterinary Congress.

Mr. HEYES (in the chair): You will remember that last year we gave a donation of £5, and my opinion is that we simply gave it as a donation, not as a yearly contribution. Mr. Garnett has applied for a further donation, and I suppose he expects another £5 for this year. It is not within my recollection that any such amount was promised, but perhaps some other member may remember more about it.

Mr. WALKER (Hon. Secretary): In the minutes of a meeting held on November 29, 1912, it states "that we agree to grant the sum of £5 to the International Veterinary Congress."

Mr. BRITTLEBANK: The Lancashire Society undertook two years ago to give a yearly donation of five guineas for three years, making a total of fifteen guineas as their contribution to this Fund. We also allocated to this Fund the surplus of the National Entertainment Funds left on our hands, but of course that was an extra. He (Mr. Garnett) may be confounding the two societies.

On the motion of Mr. BRITTLEBANK, seconded by Mr. Sumner, it was unanimously decided to leave this matter in the hands of the Committee to deal with, with a recommendation that if the funds could afford it to make a further donation of £5.

Mr. HEYES: There is another matter to which we ought to give consideration, and that is the elections. Previously we have entered into arrangements with other veterinary societies to run a candidate from this Society, and on more than one occasion, when we have had a candidate of our own, we have entered into an agreement with other veterinary societies to support their candidates on condition that they supported ours.

I should like an expression of opinion as to whether we agree to follow on the same lines in future.

Mr. FLETCHER was of opinion that if the Society was going to nominate a candidate he should be a man with a policy.

Mr. MATTINSON proposed that this Society co-operate with the Societies of Lancashire and Yorkshire, and he agreed with Mr. Fletcher that a candidate should have a definite policy; Mr. Fletcher seconded.

Mr. HEYES: I take it we are to support the other medical veterinary societies we have previously supported. There has been nothing said about a candidate from this Association. I take it there is time enough to consider that matter. I suppose if we support other societies they will support us if we have a candidate. Are the candidates chosen for any other society?

Mr. BRITTLEBANK, on the request of the President, explained that the Yorkshire Society had notified them and asked for their support for Mr. Mason. For the moment he (Mr. Brittlebank) was the nominee of the Lancashire Association, and so he did not wish to say any more about it, except that there was no other member from the Lancashire Association.

The matter was raised some years ago, when a combination of societies was found to be essential to secure an adequate representation of their men on the Council, and to a large extent that combination was very successful. Of course, it follows that if this Society puts a candidate forward the agreement will work from both sides.

Mr. HEYES: We have not had the matter under consideration, and I take it that if we do find someone anxious to go forward, if he is a desirable person, we shall support him. There is no doubt about the desirability of making the power of the veterinary surgeons felt in the Councils, particularly the Council of the Royal College of Veterinary Surgeons.

Mr. Heyes then put the resolution to the meeting, which was carried unanimously.

DAIRY INSPECTION.

WITH SPECIAL REFERENCE TO THE TUBERCULOSIS ORDER OF 1913 AND THE PROPOSED MILK AND DAIRIES BILLS FOR ENGLAND AND SCOTLAND.

By J. S. LLOYD, F.R.C.V.S., D.V.S.M. Vict., Chief Veterinary Inspector for the City of Sheffield.

Dairy inspection, we may take it, is for the purpose of ensuring a supply of wholesome milk for human consumption, and in bringing the subject to your notice to-day, I may say that I am honoured in being asked by your worthy Secretary to do so. The time at our disposal may, I think, usefully be spent by taking a short review of what has been done in the direction of dairy inspection in the past, what is being done at present, and what can be done or ought to be done in the same direction in the future. To efficiently carry out this review we must note shortly the various legal and administrative processes that have been in force, are now in force, and what are contemplated in future legislation. We must note the successes and failures of the past and the shortcomings of the present, and judge if the proposals of the future adequately meet those failures and shortcomings—in fact, are such as will tend to turn them into successes. It is, I think, generally agreed that fresh dairy legislation is required and is at hand. Now, therefore, is the time to make suggestions for any improvements that we think needed. It will be too late to do so when the proposed Milk and Dairies Bills have become the law of the land.

PAST LEGISLATION.

Several local authorities, such as London and Liverpool, have power to license cowsheds. Under the Cattle Sheds in Boroughs Act of 1866 yearly licences can also be granted in Scotland. Elsewhere in Great Britain, practically England and Wales, only powers with reservations to enforce registration of cowsheds are given to local authorities. These powers were, in the first instance, given to the Privy Council in the Contagious Diseases Animals Act, 1878, Section 34, a part of the Act which was not repealed by the Diseases of Animals Act of 1894. Section 34 reads as follows:—

SECTION 34 (*not repealed by the Diseases of Animals Act, 1894*).

The Privy Council may from time to time make such general or special orders as they think fit, subject and according to the provisions of this Act, for the following purposes, or any of them:—

(i) For the registration with the local authority of all persons carrying on the trade of cowkeepers, dairymen, or purveyors of milk.

(ii) For the inspection of cattle in dairies, and for prescribing and regulating the lighting, ventilation, cleansing, drainage, and water supply of dairies and cowsheds in the occupation of persons following the trade of cowkeepers or dairymen.

(iii) For securing the cleanliness of milk stores, milk shops, and of milk vessels used for containing milk for sale by such persons.

(iv) For prescribing precautions to be taken for protecting milk against infection or contamination.

(v) For authorising a local authority to make regulations for the purposes aforesaid, or any of them, subject to such conditions, if any, as the Privy Council prescribe.

Under these powers the Privy Council issued the Dairies, Cowsheds, and Milkshops Order of 1885, which deals in detail with registration, water supply, contamination of milk, etc., and revoked the Dairies, Cowsheds, and Milkshops Order of 1879, which, as far as I know, was the first Order of the kind made. The

1885 Order also gave power to local authorities to make regulations under the Order, but, singularly, no provision was made in regard to penalties for non-compliance with the Order or regulations so made. The great drawback was, and is, that the Order is not compulsory.

Following upon the issue of the 1885 Order came a new Contagious Diseases of Animals Act, that of 1886, Section 9 of which transferred the powers of the Privy Council under Section 34 of the Contagious Diseases of Animals Act of 1878 to the Local Government Board. Probably owing to the fact that there was not then in existence a Board of Agriculture, and possibly owing to the shortsightedness of the then Chief Veterinary Officer of the Veterinary Department of the Privy Council, the supervision of dairy inspection under a Contagious Diseases of Animals Act got into the hands of the medical advisers of the Local Government Board.

One of the first results of this transference of power in regard to dairy inspection to the Local Government Board was the issue of the Dairies, Cowsheds, and Milkshops Order of 1886, which in the main provides a maximum penalty of £5 for an offence against the Order of 1885, and a penalty of £2 per day for a continuing offence after written notice of the offence from the local authority to the offender.

The two next important legal powers in regard to dairy inspection are Section 4 of the Infectious Diseases (Prevention) Act, 1890, and Section 71 of the Public Health (London) Act, 1891, which gives the power to medical officers of health to inspect dairies (now dairies also mean cowsheds as well as dairies proper) and, provided he takes a veterinary surgeon with him, to inspect the cows therein if the milk is suspected of conveying infectious disease. If the medical officer of health is of opinion that infectious disease is *caused* by such milk, the medical officer of health shall report to the local authority, when the latter may stop the sale of such milk. Were it not for the fact that any report made by the veterinary surgeon must accompany the report of the medical officer of health (and this presumes that the veterinary surgeon must have made an inspection of the cattle before he can report) it would appear that the veterinary surgeon would only be taken to look on. He certainly is given no power under these Acts, and the medical officer of health has no power to hand over to the veterinary surgeon.

This placing of the power to inspect cattle in the hands of medical men has been most unfortunate, and whatever the Council of the Royal College of Veterinary Surgeons was doing in those days to let such a thing occur passes comprehension and has had lamentable results, as the precedent so set has been and is being followed ever since. Veterinary dairy inspection and the veterinary dairy inspector has ever since been placed completely under the medical officer of health.

Following on the above came the earlier Royal Commissions on Tuberculosis, and amongst the recommendations issued in the 1898 report were certain in connection with milk, cowsheds, and elimination of bovine tuberculosis.

Time will not permit to go into these in detail. It will suffice to state that the only practical measures taken by the Government were the issues of the Dairies, Cowsheds, and Milkshops (Amending) Order of 1899, and a set of model regulations relating to dairies, cowsheds, and milkshops, with a covering letter sent out by the Local Government Board, advising local authorities to adopt the Dairies, Cowsheds, and Milkshops Orders, and to make regulations under them.

The purport of the Dairies, Cowsheds, and Milkshops (Amending) Order was to alter Article 15 of the 1885 Order, so that the provisions of paragraphs (a) and (b), which refer to milk from diseased cows, should in clud

in the case of a cow such disease of the udder as shall be certified by a veterinary surgeon to be tubercular. To give the Local Government Board credit where credit is due, it should here be stated that the circular letter just mentioned did point out that local authorities could appoint a veterinary surgeon for this purpose. But as the Dairies, Cowsheds, and Milkshops Orders were not compulsory, little was done by the local authorities to comply with any of the suggestions of the Local Government Board, and even when regulations were made under the Orders they were, and are, only enforced in town dairies to any great extent, and even then in too many instances with only drastic effect—the elimination of town dairies.

What with the exorbitant demands of medical officers in regard to dairy sanitation and the supervision of sanitary inspectors—many of whom had no practical experience or knowledge of the housing of cattle and the detailed structural requirements to ensure clean and healthy cows—many of the renovated buildings failed to provide the sanitary conditions required. Such enforcement of dairy regulations did not meet the approval of the cowkeeper, who was required to keep his cows clean, or of the property owner, who was compelled to execute alterations to buildings in order to comply with the requests of faddists, and which when completed did not give the satisfactory results anticipated.

In rural districts for many years no regulations were issued, and it is only in quite recent years that the Local Government Board, through county medical officers of health, has brought sufficient pressure to bear to get this done, and it is greatly to be feared that even now these regulations are not enforced. In passing it may be mentioned that it is very probable that the Local Government Board were acting *ultra vires* in dealing with tuberculosis of the udder in milking cows, as their power was vested under a Contagious Diseases of Animals Act, and tuberculosis was then not scheduled under that or any other Act. The right or wrong of this, however, did not matter much, as it was only to a very limited extent that local authorities took any such action under the 1899 Amending Order.

The most progressive local authorities—those of our largest cities—however, were not content with the powers given to them by the Orders, as owing to the application of the latter being purely local they gave no supervision over dairies, cowsheds, or cows in rural districts from which large supplies of milk were being daily consigned for human consumption in such cities. Consequently, in 1899 several cities, of which Manchester was one of the pioneers, went to Parliament for further powers, the result being the inclusion of what are now known as the tuberculous milk clauses in several local Acts.

Here, again, following the precedent of the Infectious Diseases (Prevention) Act, 1890, all the power to deal with tubercular infected milk was given to the medical officer of health, the veterinary surgeon again having to take a back seat.

A considerable number of towns have since obtained these powers, and where they have been persistently enforced a considerable diminution of tubercular infected milk supplies has followed, the percentage in some towns having dropped from twenty or over to as low as five. The latter figure has, however, not been maintained, and the cause is not far to seek. The action under the tuberculous milk clauses only finds the tubercular cows some time after the udders have become affected; the action does practically nothing to remove the sources of infection from other cattle, and consequently the supply of cattle affected with tuberculosis of the udder is not persistently and constantly diminished. Instead, there is a persistent, if variable, number of tuberculous milking cows constantly in the dairy

herds of this country, with the consequence that not less than 10 per cent. of the total milk supplies of large towns are generally infected with tuberculosis. It should be mentioned here that the tuberculous milk clauses give local authorities possessing them power over milk supplied either within or without the area of such local authorities. Infected milks sent in from rural districts can be followed and the implicated cows examined. County local authorities keenly resent this outside inspection by the officials of city authorities, especially when, as in some cases, milk is supplied from the same district, and possibly from the same farm, to more than one city. In such cases there is a possibility of multiple inspections, which the offending local authority state is unnecessary and irksome. The Milk Bill, as we shall presently see, tries to remove this difficulty, but it appears to me, and as I shall try to prove, in a very inadequate manner. Somewhat similar proposals are embodied in the milk clauses of the Borough Police (Scotland) Act, 1903. The powers of the tuberculous milk clauses are given to local authorities in their own areas, but in case of outside areas the responsibility of finding the cow or cows with tuberculosis of the udder or giving tuberculous milk is thrown upon the medical official officer of health and veterinary surgeon of the district from which the tuberculous mixed milk was first supplied. Otherwise in Scotland and in Ireland the Orders and Regulations relating to dairy inspection are on similar lines to those already detailed for England and Wales.

Additional powers for action towards the prevention of tuberculosis amongst people and the elimination of tuberculosis from amongst cattle, however, have been granted to Ireland. The Tuberculosis Prevention (Ireland) Act of 1908 is a comprehensive measure, and amongst other means taken in the interests of human beings is the power for local authorities to appoint bacteriologists and veterinary inspectors. It should be noted here that only medical practitioners can be appointed bacteriologists—another injustice to the veterinary profession.

In 1909 the Local Government Board for Ireland made a General Order, cited as the Sanitary Veterinary Inspectors Order of 1909. Under this Order local authorities may, and when directed by the Local Government Board for Ireland, shall appoint veterinary sanitary inspectors for the purposes of dairy inspection in co-operation with the medical officer of health, but attending the meetings of the sanitary authority and reporting direct to that authority. I am not aware how many of these appointments have been made, but trust they will become universal throughout Ireland, as they are a distinct advance from a veterinary point of view upon anything yet done in Great Britain.

Towards the elimination of tuberculosis from amongst cattle Ireland again leads the way, as in 1910, the Bovine Tuberculosis Notification (Ireland) Order of 1910 was made by the Department of Agriculture and Technical Instruction for Ireland. This Order requires similar notification to the Tuberculosis Order of 1913, but only to the police, who in turn must notify the Department of Agriculture and Technical Instruction. What the Department has done in such cases I do not know.

PRESENT LEGISLATION.

As you will have gathered from my previous remarks most of the Orders and Regulations dealing with dairy inspection are still in force. One Order now in force—although not dealing strictly with dairy inspection, but practically being, and intended to be, of considerable benefit to both producers and consumers of milk—remains to be noted, and that is the Tuberculosis Order of 1913. As the Order is so recent, and consequently is in the knowledge of all present, I need not deal with

it in detail, but would like to draw your attention to the main points, and have pleasure in handing round copies of the Order for reference. As you will see, Articles 2 and 3 require notification by owner and veterinary surgeon. Article 4 deals with veterinary inspection and diagnosis, which, when positive, requires slaughter of the diseased animals under Article 5. Before doing so, however, the animals have to be valued under Article 6, and here the trouble begins, as owners and valuers have very different ideas regarding the value of diseased animals, the trouble being accentuated by the fact that two (tuberculous and non-tuberculous) valuations have to be made. Article 7 provides for the post-mortem examination, and is important in that the amount of compensation paid under Article 8 depends upon the post-mortem certificate. Article 9 and 10 deal with the use of milk from and the detention of diseased animals respectively, and in themselves are very important, as also is Article 11, which deals with veterinary inspection of markets.

It appears to me that now is a convenient time to shortly mention the failings and shortcomings of past and present dairy legislation and inspection, as it is only by having these in our minds that we can adequately consider the proposed Milk and Dairies Bills. I will take these in numerical order as they have arisen in my previous remarks, and point out how in the respective Bills for England and Scotland they are or are not dealt with in an efficient and satisfactory manner.

Licensing v. Registration of Dairies and Cowsheds. In my opinion licensing is far superior to registration. This has been recognised in regard to slaughter-houses throughout the country, and has been found very effectual where the power to license already exists. Licences have to be applied for, certain conditions apply, and when such conditions are not met the local authority can refuse or revoke such licences. Usually licences require renewal yearly, hence local authorities have ample opportunities to deal with defaulting licensees. Under both the Milk Bills only registration is provided for, certainly with conditions, but refusal is subject to appeal, and registration can only be revoked by a court of summary jurisdiction, with appeal to quarter sessions if desired. Annual registration is not required.

Adoptive v. Compulsory Dairy Legislation. Under Clause 6 of the Scottish Bill local authorities are required to make bye-laws to deal with the inspection of cattle, dairies, and cowsheds; for the prevention of impurities; and for precautions against infection. There is no such clause in the English Bill, but Clause 15 reserves power to the Local Government Board to make Orders dealing with such matters—a power which seems to be a favourite with the permanent officials of the Local Government Board, one which all agricultural bodies resent, and one which will, as under the Public Health (Regulations as to Food) Act, not be used to the advantage of the veterinary profession. This clause ought to be deleted, as no Government Department should be trusted with such autocratic powers. Either the Scottish clause should be inserted in the English Bill, or the bye-laws themselves should be embodied in it.

Uniform Inspection. If the bye-laws were embodied in both Bills this would result, as all parts of the country would be served alike, not so much in detail as in principle. Adequate lighting, efficient ventilation, sufficient cubic space, impervious floor, proper drainage, satisfactory disposal of manure, etc., would all be obtained, due consideration being given to the respective requirements of urban and rural districts, a minimum, however, being fixed for each district.

Owner v. Occupier. Structural alterations reasonably necessary for the legal use of premises for dairy purposes have, under Clause 16 of the English Bill, to be borne

by the landlord. This clause does not appear in the Scottish Bill, which would be greatly improved by its inclusion. The English clause is apparently on similar lines to that of the Factory Act, which has been found to work well.

Efficient Administration. As pointed out previously, most owners and occupiers of cowsheds and dairies have objected to the requirements as being faulty owing to inefficient administration. Under the English Bill practically all power is to be given to the medical officer of health. In the Scottish Bill three sets of officials have statutory positions—medical officers of health, veterinary inspectors, and sanitary inspectors. So far as dealing with human beings, human disease, human infection, the medical officer of health should be supreme officer, and, so far as I know, no one wants to interfere with his powers or position. Regarding the interests of animals, I deny that he is the proper person to have full control. His training and experience do not warrant it. His efforts of the past, either in relation to cows, cowsheds, or disease of cattle (as witness the Hendon and such-like cases) do not support it. It is also questionable if the sanitary inspector is any better qualified to inspect the sanitary condition of dairies and cowsheds, and this is apparently recognised in the Scottish Bill, Clause 4 giving equal power to the medical officer of health, veterinary inspector and sanitary inspector to inspect dairies and make reports. Where one sees stalls for cows 8 ft. 6 in. long, with a corresponding width, a drop of only two or three inches from the heel-stone to the dung channel, sufficiently numerous air inlets to blow the cows out of the cowsheds, a lowered outlet in the roof 11 ft. long and 3 ft. wide, one wonders where sanitary inspectors demanding such conditions have obtained their knowledge of the sanitary requirements of cowsheds; such knowledge is certainly not the outcome of practical experience, or an acquaintance with the essentials of efficient animal health. Only persons fully acquainted with the hygienic requirements of animals, both in health and disease, should have the the supervision of sanitary conditions necessary for the successful housing of cattle, and it cannot be contradicted that the practical veterinary surgeon is best fitted by education and experience for this work.

Veterinary Inspection. In past dairy legislation failure has largely been due to lack of organised and adequate system of veterinary inspection, and even in the new Tuberculosis Order this is not provided for, the success or failure of the Order being to a large extent left to the manner in which the notification clause is complied with by owners and practising veterinary surgeons. Where the tuberculous milk clauses have been most successful has been where there has been systematic veterinary inspection, the experience being in Sheffield that the more individual examinations of cows made in a year the greater number of tuberculous udders found. The same experience holds good in outbreaks of parasitic mange and glanders; the greater the number of in-contact animals examined the greater the number of affected animals found, and the more successful the working of the Orders becomes.

In the Scottish Milk Bill, Clause 3, the appointment of veterinary inspectors is on similar lines to those already mentioned as occurring in the Irish Sanitary (Veterinary Inspectors) Order of 1909. That is, local authorities may, and when required by the Local Government Board shall appoint veterinary inspectors under the Act. The appointments, however, are amplified in the Scottish Bill, in that the veterinary inspector has a statutory position, must not engage in private practice without the consent of the Board, has security of tenure of office, or cannot be dismissed without the sanction of the Board. The veterinary inspector on appointment can nominate a deputy, and under Clause 4 of the Bill must inspect the cattle in every dairy in his district at

least once a year. This, of course, does not preclude him from making a more frequent inspection if he wishes to do so. Somewhat similar power of appointment is given in the English Bill, Clause 14. This clause, however, also gives county and sanitary authorities power to employ any inspector or other officer (lay inspectors) appointed under the Diseases of Animals Act, 1894, and to employ a bacteriologist. Seeing that in the Irish Tuberculosis Prevention Act, 1908, bacteriologists must be medical practitioners, and seeing that the Local Government Board for England in 1899 recommended that inspectors of nuisances should be appointed lay inspectors under the Diseases of Animals Acts, to act under the medical officer of health, this clause requires watching by the Council of the Royal College of Veterinary Surgeons, otherwise it will certainly be used as a means to get only medical men appointed as bacteriologists, and to get the administration of the Diseases of Animals Acts under the supervision of the medical officer of health as is done to-day in Liverpool, Nottingham and other towns that I can mention. The English Bill does not demand systematic veterinary inspection in any form. To get the best out of the Diseases of Animals Acts and Orders (including the inspection included in the proposed Milk Bill), I am of opinion that as far as veterinary inspection of animals and sanitary inspection of houses for animals are concerned this work should be carried out by a veterinary staff in the employ of county and county borough councils and working under the supervision of the Board of Agriculture and Fisheries. I do not think the administration should be handed over to medical men or left in the hands of the police. The frequent visits of the latter in connection with the working of the Tuberculosis Order is, I know, resented greatly by owners of cattle in country districts, and is greatly interfering with notification under and the successful working of the Order. That a central authority is necessary to supervise the work and to spur local authorities on is very evident from the unequal manner in which the Tuberculosis Order is now being worked in different districts. In one large county I know, having a cattle population of 150,000 head, all the veterinary inspection under the Order is being done by one part-time veterinary inspector. In that and other counties, owing to opposition to the Order, chiefly on account of the large expense entailed by administration and compensation, with only a minority of the latter coming from the national exchequer, whilst the whole of the former falls on the county rates, the efficiency of the Order is being greatly curtailed, and the good results anticipated by the Board of Agriculture are not being realised.

My own idea of administration would be the appointment of whole-time veterinary officers for each county and county borough, to supervise and control the veterinary work for his district, the actual work of veterinary inspection being left in the hands of local practitioners. Indeed, I see no reason why practising and notifying veterinary surgeons could not deal with all cases arising in their practices, subject, of course, to the guidance, and if necessary, assistance of the country veterinary officer. The latter should be provided with a laboratory properly equipped and licensed for the biological examination of milk, etc., his work in turn being supervised by the Board of Agriculture. At least half of the expense of administration and compensation should be borne by the State.

Status of Veterinary Officer.—I cannot pass from this matter without a word regarding the status of the majority of present whole-time veterinary officers. Nearly all are subordinate to the medical officer of health, a position which is very deterrent to the status and pay of the veterinary officer, and which will have to be radically altered if the work of veterinary surgeons in public health matters is going to take the place

of the inroads in veterinary practice resulting from the coming of light and heavy mechanical haulage and the decreasing number of horses requiring veterinary treatment. Owing to the subordinate position the work of the whole-time veterinary inspector does not receive the recognition it requires or deserves. The veterinary officer is looked down upon as an inferior official; his reports often go to medical officers, who smother them or edit them; the veterinary officer in many cases does not attend committees dealing with his work unless it is necessary for him to be present to take blame that should fall often on other shoulders and to receive the consequent "slating"; the pay is often very inadequate and almost impossible of being increased. I will give briefly four examples all in one county. (1) It has taken twelve years to get a total annual increase of salary amounting to £125 per annum; (2) it has taken seven years to get a total annual increase of £35 per annum; (3) a few years ago a veterinary inspector for a county borough was appointed at a salary of £130 per annum; (4) a veterinary inspector holds his appointment as one of the staff of the Chief Sanitary Inspector—a layman. Someone in authority wants to look into these matters. It is not the way that the medical officers are dealt with. Thanks to the care of the Local Government Board, it is seldom that a whole-time medical officer is appointed at less than £500 a year, and the Local Government Board is now making further inquiries into such salaries. I feel that I have probably taken up too much of your time in dealing with matters already mentioned. There are, however, a few others that I would like to put forward for discussion, more particularly in connection with the Tuberculosis Order and the Milk and Dairies Bills.

Notice of Disease.

2.—(1) Every person having in his possession or under his charge

(i) any cow which is, or appears to be suffering from tuberculosis of the udder, indurated udder or other chronic disease of the udder; or

(ii) any bovine animal which is, or appears to be suffering from tuberculosis with emaciation

shall without avoidable delay give information of the fact to a constable of the police force for the area wherein the animal is, or to an Inspector of the Local Authority, and the constable or Inspector shall transmit the information to the Local Authority, who, if not themselves the Sanitary Authority, shall inform that Authority.

(2) The person in possession or having charge of the animal shall forthwith take such steps as are necessary to secure compliance with Article 9 (*Precautions to be adopted with respect to Milk, etc.*) and Article 10 (*Detection and Isolation of Suspected Animals.*)

Scope of the Tuberculosis Order.—Most veterinary surgeons want to know when an affected bovine animal becomes emaciated. I think the Order should be widened so as to include cattle actively capable of disseminating infection to other cattle, as proved by finding tubercle bacilli in any of the discharges, and no matter what the condition of the animal is. The better the condition the more likely is the carcass to be fit for human food, and consequently the more valuable the salvage.

Cost of Administration.—At least half of this, as well as half of the compensation, should be borne by the Exchequer. The working of the Order would be greatly extended and the results more beneficial.

Stoppage of Milk Supplies.—Tuberculous milk should be dealt with under the Tuberculosis Order, but in case of tuberculous milks from the county the city and county veterinary officers should work in conjunction, otherwise there is a possibility of the cows with tuberculous udders being lost sight of. This is already occurring in some districts, the county local authorities

actually encouraging farmers to sell their tuberculous cows to the butcher or dealer in order to save expense under the Tuberculosis Order. Regarding milk-borne diseases, the medical officer of the consuming district ought to be able to temporarily stop the suspected milk coming from the producing district, instead of having to get the medical officer of health and local authority of the latter district to do so as proposed in Clause 3 of the English Bill and Clause 15 of the Scottish Bill.

Disposal of Suspected Milk.—The Tuberculosis Order, Article 9, orders that the suspected milk shall be sterilised, but does not state what is afterwards to be done with it. It should be made clear that all suspected milk must be sterilised before being fed to pigs or other animals, and that all diseased milk must be destroyed.

There are numerous other matters which occur in connection with dairy inspection, but I have already trespassed too far on your time. Doubtless some of them will be mentioned in the discussion to follow. I shall be glad to hear your opinions on matters mentioned or unmentioned. I am here to learn quite as much as to teach. I have been pleased to be present and to have the opportunity of addressing you. I thank you for your attention.

DISCUSSION.

Mr. BRITTLEBANK: I rise to congratulate my old friend on the very happy manner he has put the material before us. We know his capacity for writing papers, and the lucidity with which he brings the points within the reach of all. I have very little criticism to offer, naturally our interests have been very much in the same field and are practically in unison.

My own feeling is that, without discussing Milk Bills or the legislation we have got, the whole subject should be approached from a somewhat wider basis. My opinion was asked fairly early on as to what I thought of the Milk Bill. Well, I read it, and I re-read it, and I said at the finish I thought it was "rotten."

It seems to me to mark very little advance on the legislation we had before. I have expressed over and over again that with certain reservations I thought the Dairies, Cowsheds, and Milkshops Order was better than anything that appeared in the Milk Bill taken in the House last year. I am referring to the English Order.

It seems to me that under the existing Dairies and Cowsheds Order enormous power was given to the inspector who was appointed to a proper position. He would then be left with discretionary powers of a wide character. I do not admit that a man having great power will invariably use it unfairly; on the other hand, it would be utilised for the general good. If the Dairies, Cowsheds, and Milkshops Order were revised where necessary and brought up to date, made compulsory, and placed in the hands of the large administrative bodies, such as the County Councils, to administer, it would not be long before an enormous improvement took place generally. Clearly, the proper person to administer the Order would be a veterinary surgeon, whose official position should be clearly defined. The whole question is, or should be, a National one. These little things, such as Milk Bills, Orders, and so on, seem to me to be only tinkering with the matter.

I have always thought that if the great body of agriculturists could be brought to recognise through its main society, such as the Royal Agricultural Society of England is, the great value which would accrue to the bovine and equine stocks of this country by the establishment in the first instance of a complete veterinary service throughout the country, it would not be long before such a service were an established fact.

It seemed to some members of the profession that one is out to push the claims of the whole-time officer. The

whole-time officer, to my mind, must be an essential part of any such scheme. But no whole-time officer or officers could possibly work without the paid assistance of the men in practice. They should, and must be, an integral part of the whole scheme.

A further point in dealing with the diseases of animals is, I think, that at present there is too much centralisation of control. Every County Council should administer and be responsible for the control of all animal diseases in that county. It should be responsible, of course, to a central authority. Every county should have a completely equipped veterinary staff of whole-time officers. Every district should have a part-time officer, who would be a practitioner, and who would work in conjunction with the whole-time officer.

By a scheme of that sort the activities of the veterinary officers could be directed in many directions other than tuberculosis. Everything nowadays seems to hang round tuberculosis. I, personally, live on it. The consideration of one disease, and one only, is a mistake, and we should lay our claims before the community in a much larger sense. If you could get such a staff created, naturally you would not be long before you instituted a system of proper control. Most of the veterinary officers at present serving as whole-time officers have their range of activities limited, and their attentions confined to certain directions.

There is another difficulty which has always appealed to me, though it is the same wherever you go, in a rising profession such as the veterinary. It would be difficult to secure administrative positions without being subjected to control from somebody. Of course, I know there are very many objections to be raised in the experience of work with medical officers; happily, my experience has been somewhat different. But as far as I can see in the work of large corporations there are two separate classes of people in control—one a professional man, the other a layman, usually termed a superintendent—and as far as I can judge from what I know of the relationships, I would sooner work with a professional man than with a layman. I agree entirely it would be extremely desirable to obtain these administrative positions and be directly responsible ourselves to our committees, but I question, for the time being, whether we are strong enough, though we may be ultimately.

With regard to the transference of the control of dairy inspection from the Local Government Board to the Board of Agriculture I have no very serious feeling. It seems to me there is some justification for it being under the control of the Local Government Board. It is a good many years ago now since I first got up to speak on this question—I think it was at the Sanitary Congress some twelve or thirteen years ago—and I said then that the profession should press for the appointment of a veterinary officer at the Local Government Board, and I think the profession should go on pushing until they secure what they require. At present I think it is only due to the fact that there is no veterinary officer there, that we cannot get the recognition we justly deserve. If you have a veterinary officer there, he would be in the same position as a whole-time veterinary officer working in a county, and act as your representative at headquarters, to explain matters from a veterinary point of view.

Some of the details Mr. Lloyd referred to are interesting, and one most important is the question of instituting a system of licensing instead of registration. There is no question of doubt in my mind that to secure proper control nothing short of licensing is necessary. Registration is a farce. It simply means that a man has to apply to the sanitary department of the district in which he lives, and they are compelled to register him, no matter what the conditions. After that they can

start to proceed against him under the Dairy and Cowsheds Order. In the county districts most of them are concerned in this particular business of farming, and the local Council are likely to be hard on their friends or, it may be, themselves.

Mr. Lloyd made a point also that I regard of very great importance, that is that the veterinary officers should prescribe the conditions of the housing of cows. I was in Staffordshire only this week, when a farmer showed me, with some pride, a new cowshed which had been built for him. I said, "How long has it been built?" He answered that it had been finished last summer. I then said, "Whoever built it deserves a public testimonial, because it is very nearly as bad as the dirty old place over the way." In the new cowshed there was not a single provision made for any drainage, and there was only one provision for light, which contained two small panes of glass, each about 12 in. by 8 in. If these are the modern conditions of alteration to property, can you wonder that when veterinary officers come down and find fault that the people who have to build these places resent it? Can you blame them? Later on, when the whole scheme of reconstruction comes forward, the man will have to reconstruct entirely, and thus do a lot of work twice. Certainly I agree with Mr. Lloyd in approving one feature of the new Milk Bill, that the cost of reconstruction should be on the landlord. There has been a tremendous amount of hardship imposed on the people who are the milk producers under the existing conditions. Many of these men, unfortunately for the general conduct of the business of dairying, are small men who live from hand to mouth, and whose financial reserve is practically nil, and they cannot afford to carry out extensive alterations.

Mr. Lloyd mentioned the large expense of administration of the Tuberculosis Order. I am not quite up to date with my information, but it seems to me that the expense of administration of this Order is nothing like so large as was contemplated. Of course, Mr. Lloyd has also pointed out how certain county authorities have carefully avoided their responsibility.

Most of the valuations made under this Order are left in the hands of veterinary inspectors, and I am bound to say that I think in many of the cases I have seen the valuations are grossly unfair, and are very much too low. I do not think the Board of Agriculture ever contemplated that the valuations should be kept below a fair scale, but they should not be in excess of a fair and square valuation. I will give you an instance of a case which cropped up a little while ago.

A cow under the first valuation was valued at £20 10s.; she was a big fat cow in excellent condition. The second valuation was £4 10s., that is, as a tuberculous animal. There may be some grounds for making a valuation like that, but I cannot for the life of me see how any practical man valuing a cow in the first instance at £20 10s. can assume from her condition that the tuberculosis was so extensive as to make her only worth the fraction of £4 10s. as a tuberculous animal. A great deal of resentment has been caused through this second valuation amongst owners, and I think a little more generosity in this direction would secure a good deal more co-operation, and be better for the administration of the Order.

I believe the Board hope some day to achieve the complete elimination of tuberculosis. I agree that at present it would be decidedly helpful to include all those animals which show active tuberculosis, but I think there are many cases which do not come under this Order which are decidedly infective, and which provide a good deal of difficulty in finding of bacilli in the discharges. I have in view a cow I have had under my observation for some time. She is a cow that has not

got tuberculosis of the udder, nor is she emaciated, but she has got tuberculosis of both lungs, well marked; of that I am confident. She has reacted readily to the tuberculin test, and yet we have not found tubercle bacilli in her discharges. My experience with these animals is that they suddenly collapse. You will find they hold their own for some time, and the disease does not make much progress, but a careful physical examination reveals what is going on in the lungs. I do think animals of that description should be brought within the purview of the Order and removed from contact with other animals.

Mr. MATTINSON: I should like to make some observations on the question of valuation. I do not know what the Board of Agriculture have in mind in advising that the valuation should be kept down.

I have just had a case in which a cow valued by the owner at £8, and £6 if tuberculous, actually realised £4 for beef.

In Preston some time ago there was great fear of the County Council appointing whole-time officers. Personally, I think a part-time veterinary inspector would not act (?) as a private practitioner as against part-time inspectors.

Apart from Mr. Lloyd's paper, I think if all part-time inspectors were to use tact and diplomacy the Orders of the Board would be carried out more efficiently.

Mr. SUMNER: I have had the honour of being inspector for the Borough of Bootle, adjoining Liverpool, and some of our ways and means are much on the same lines as theirs, only we have a definite inspection of all cows, udders, and dairies every three months. We have had that now for a great many years, and at the commencement of this inspection the number of cows with tuberculous udders, and tuberculous cows was something appalling. Now, I am pleased to say that the cowkeepers themselves are almost as jealous of having clean udders and clean cows as the veterinary inspector. They have tried all in their power to work with him as far as they possibly can, and I congratulate them and the borough on the improvement made.

The state of the shippens is looked after by the sanitary inspectors. They go round, and if I see anything objectionable in the condition of the shippens or the cows, all I have to do is to drop a postcard to the inspector to go round on a certain day, and he does it without any friction at all. Speaking about the friction between the private practitioner and the veterinary inspector, if there is another veterinary practitioner attending to the horses, we do not go to see them without first notifying their private veterinary surgeons and making an appointment at the same time.

Speaking about compensation, there are a lot of cowkeepers in the borough whose cows are in good condition and fairly valuable, and lots of them—taking them at double valuation—run to anything under £30, say £15 to £20. I have told them the conditions of the two valuations, and pointed out that if a cow proved to be tuberculous in any way they would only get three-fourths of the value of the carcase. Most of them, in fact all except one, have readily agreed to the conditions. One of our officers must go and see the cow before she is sent away, and they can see her killed.

Fortunately, in Liverpool, as a rule they get full compensation, which I think saves a lot of trouble and expense.

Mr. BRITTELBANK: May I just explain that I purposely made my remarks about keeping down the valuation in the vague way in which I did because I do not want to make any specific accusation against any authorities, but in the hope that the remarks made at this meeting may be brought to the attention of the officers of the Board of Agriculture, and dealt with by them.

Another point is of considerable importance in this Order, and that is the slaughtering of these animals in

certain districts. In most of the districts in which I work around Manchester I have a working agreement with the local veterinary inspector, so that I may be present at the post-mortem. It has occurred to me many times that far greater powers should be given to the local veterinary inspector to give a farmer permission to remove a cow to some recognised place for slaughter.

I have in mind a case which occurred a little while ago of an eminently respectable farmer—one of the best of fellows—just outside Manchester, who had a cow suffering from tuberculosis of the udder. It was necessary for me to make two visits to find out which cow it was. I was only able to do so by deciding she was in a certain group of eight cows, then taking a sample from each of the eight cows in that group, there being no cow which presented any suspicious udder symptoms of even the slightest character. We will agree that particular gentlemen had committed no very serious crime. An appeal was made on his behalf to allow him to take his cow to a knacker yard and have it killed there. The police insisted that the cow should be killed on the premises. I pointed out that he could defy the police and waive his right to compensation.

Another point: Such cows should not be slaughtered on the farms, but taken to the central places and slaughtered under proper conditions. I think this is a matter of some importance, to a farmer at any rate. Many of the men I have come in contact with have been treated as if they were criminals, and it is wrong.

Mr. BURDRED: I wish to congratulate Mr. Lloyd on his paper, especially as I have been associated with him in the past in this work.

There are two points which appeal to me specially in regard to valuation. In Manchester they value a cow from a beef standpoint, and it is a very unfair valuation to make. For instance, a dairy cow which may be worth anything up to £30 would not be worth more than £7 or £8 from a beef standpoint.

Mr. FLETCHER: I am pleased to hear Mr. Lloyd on this question. We know he is very good in doing anything—either individually or collectively—for the advancement of the profession.

In relation to the question of a man being able to send a beast to a slaughterhouse without having to go through any of the procedure of this Act, I think there will not be that interference which seems to exist at present. If a man is agreeable for the beast to be sent to some place to be slaughtered and is prepared to take all the risk himself, it would be a saving of expense to the local authority, and it would be an end to that particular beast spreading disease amongst cattle. Perhaps I am fortunate in regard to the police not going to the premises and becoming a source of annoyance to the owner. It does not exist with us, as the police leave it almost entirely to me to deal with cases of detention and isolation, and should it be a case requiring disinfection I notify the police, and they instruct a man, and the thing is done. There is not much trouble about that. Unfortunately, perhaps, it is only because the Act has not been in existence long, and as we are getting to know the cases of tuberculosis with emaciation, in a large majority there is no need to look for the line of demarcation. Of course, in making a preliminary report you have to say whether it is a case of emaciation or not at that time, and your compensation always should only be quarter value. It does not matter what lesions you find in your post-mortem, you only get your quarter value. But I have also taken a large number of cases without thinking of testing, and I have not yet had to regret having done so. I think Mr. Brittlebank said once before at a meeting, that with experience, as time goes on we should be able to diagnose to a great extent whether there is tuberculosis or not, and whether to use the tuberculin test. It means, of course, if you

go through the whole process and compare the cost of administration and valuation and what the farmer gets, one finds that the administration costs look rather heavy, and so, whatever I have been convinced that it is not necessary, I have not used the test.

There is a case Mr. Brittlebank mentioned about tuberculosis with discharges. It has struck me very often that we see very little in literature or in teachings about finding bacilli, when the lungs are affected, in the sputum of an animal coughing. I went to that trouble with one or two cases, and I was quite pleased that I was successful, and I slaughtered on that, and so proved that the lungs were very badly affected.

If we endeavoured a little more in these particular cases of lung affection I think we would be entitled to slaughter. I look upon it as a means of stopping the spread of disease amongst cattle and preventing it from spreading to the milk.

There is no doubt that we shall get some further powers, and with further experience, one feels that with the scope the Bill gives and with some general inspection, and if notification is not to be of the haphazard kind it is now, the better it will be for the Order.

Mr. HEYES: We have had a very good discussion on Mr. Lloyd's paper, and many will go away enlightened by the paper and the discussion. I am in agreement with the sentiments expressed regarding the necessity for some representation of our profession at headquarters. In my opinion many of the authorities, not only head authorities, but the subordinate authorities, deal in a way not acceptable to the case. They are unaware that there is a better course. The duty devolves upon us of expressing our opinions to those authorities through the medium of our representatives in the Council. It is obvious that the Local Government Board are not aware of the qualifications possessed very largely by veterinary surgeons to-day. For instance, they do not seem to recognise that there are many veterinary surgeons who are expert bacteriologists.

I am pleased to learn to-day that at Manchester the inoculation test is employed for the detection of tuberculosis. I think that in the administration of the Order we can show ourselves competent; there are many men thoroughly competent to carry out all that is required.

Recommendations have been made to the veterinary surgeons by various bodies about the means that ought to be adopted for the detection of the disease; for instance, microscopic examination, and Mr. Fletcher to-day has mentioned the tuberculin test. To my mind, whilst both of these examinations would greatly assist the inspector, yet it must often happen that a further examination is necessary, and that examination can only be made by a man who has made a speciality of bacteriological work. I know that many veterinary surgeons have qualified in this direction, and it should be known to the authorities who have to formulate the laws, and who draw up the lines on which we have to proceed, that veterinary surgeons are able to conduct all the tests which are necessary to detect this disease.

It has been mentioned here to-day that occasionally friction occurs between practising inspectors and other practising veterinary surgeons. Discourtesy on the part of inspecting veterinary surgeons does, I know, exist, and is brought into operation frequently. It does not assist in efficiently carrying out the work of inspection.

Mr. LLOYD: I have been somewhat disappointed, because I thought you would probably try to pull my paper to pieces with criticism, but it has been more of a pleasure than a disappointment to me that the discussion should have taken a very wide range of subjects, and certainly I think it has followed well upon the lines of the paper.

Mr. Brittlebank thought that we ought to get assistance from the Royal Agricultural Society. That has been in my mind all along, and I do not know how I

came to leave it out of my paper. I thought of it afterwards, and I feel that the veterinary profession should have gone to the higher powers and got them to work together; but, as Mr. Brittlebank has said, we are a young and rising profession, and we have to feel our way. I must insist upon this: it is no good veterinary surgeons being educated and taking up whole-time posts, and then to be placed in subordinate positions under health sanitary inspectors.

Professor Share-Jones has said that in Scotland the sanitary inspector is responsible to the health committee just as the medical officer of health is. I think I was right in saying that I do not expect the veterinary inspectors are going to get all they want, but we certainly ought to go for all we want. My position is this: every man to his own trade, just as the cobbler should stick to his last.

Mr. Brittlebank made a very useful suggestion in regard to the supervision of buildings, and I quite accept his view, not only as regards cows, but equally so in regard to all animals. In Sheffield we have horses kept in places not even fit for a fly. There is no doubt that the supervision of these buildings should be in the hands of someone who understands them. Architects putting up new picture palaces do not know much about cowsheds. In Sheffield the building surveyor under the city engineer gets the plan of a cowshed which is to be built, and sends it to the medical officer of health, and in that way we get fairly satisfactory results, and it is, I may say, a uniform way of dealing with cowsheds.

Mention has been made of the cost of administration in comparison with the cost of compensation. A recent case came to my notice where the cost of administration was above five times the cost of compensation, and they say it was a great hardship on the local ratepayers to have to find this money when the Exchequer have paid for one-half and nothing at all towards the compensation. If more were paid from the State we should get better results. In Sheffield the question of valuation and the working of the Order altogether, is left in the hands of the veterinary inspectors.

My method is to go to a farmer who has notified a cow with tuberculosis and emaciation, and I put it definitely to him what his cow was worth when she was in health. In the majority of cases I find he has not valued the cow as he ought to have done. If it is a cow worth £20 reckoned as a dairy cow, and if she has got marked tuberculosis of the udder, that cow is slaughtered under the Tuberculosis Order, and if the carcase is passed as fit for food, the compensation would be ten guineas—three-fourths of £14. In one case recently the compensation was £7 11s. 1d., and that amount was paid over to the owner of the cow; we got nothing of it.

Mr. Mattinson has mentioned the question of excess amount. If an animal makes more than the valuation the authorities, after deducting their expenses, must pay over that excess amount to the owner. Even if it is only a matter of, say, 5/-, the owner would be entitled to it.

Mr. Fletcher stated that he had not been so successful in dealing with microscopical examination of the discharges. Mr. Brittlebank gives an instance where he was unable to get it. I believe in Germany they go a good way towards finding tuberculosis in the discharges.

Mr. Sumner has mentioned about the quarterly examination of cows. I can quite bear him out in regard to the importance of this, and its benefit to the cow-keeper and the people who have to drink the milk.

Mr. FLETCHER: I must confess that Mr. Lloyd is wrong in regard to the question of administration expenses. The matter came before Parliament, and I feel convinced the reply was to the effect that they could not deduct any administration expenses from the sale of the carcase. It must go back to the owner.

Mr. WALKER: Mr. President and Gentlemen, I would like to propose a very hearty vote of thanks to Mr. Lloyd for bringing this excellent paper before us, and I am only sorry that the attendance has not been larger.

Mr. BRITTLEBANK: May I have the pleasure of seconding the vote of thanks? It is a subject which has concerned me for some time, and I always like to hear my old friend, Mr. Lloyd, on this evergreen topic.

Mr. J. P. HEYES (President) proposed, and Prof. Share-Jones seconded, the following resolution, which was carried unanimously, with the recommendation that copies of the resolution should be forwarded to (1) Local Government Board; (2) Royal College of Veterinary Surgeons; (3) Council of Royal Agricultural Society of England; (4) other veterinary societies.

"That this meeting of the Liverpool University Medical Society is unanimously of opinion that the lack of direct representation of the veterinary profession at the Local Government Board seriously retards the effective administration of veterinary work through the local authorities of this country, and respectfully, but strongly, urges in the best interests of public health, as affected by disease in domesticated animals, the institution of a Veterinary Department at the Local Government Board under the control of a veterinary officer who is a fully qualified veterinary surgeon as an immediate and urgent necessity."

Mr. BRITTLEBANK proposed, and Mr. J. Sumner seconded, a hearty vote of thanks to the President (Mr. J. P. Heyes) for his conduct in the chair.

A. WALKER, Hon. Sec.

VICTORIA VETERINARY BENEVOLENT FUND

The quarterly meeting was held at 10 Red Lion Square, London, on Thursday, Jan. 8th. There were present:—Messrs. R. C. Trigger, President; E. A. West, Chas. Sheather, S. Slocock, S. Wharam, G. Banham, J. Abson, W. Burt, W. Freeman Barrett, Nicholas Almond, F. W. Garnett, H. Sumner, and W. Shipley, Hon. Sec.

Apologies for absence were received from Prof. Penberthy, Messrs. J. Dunstan, and P. J. Simpson.

SECRETARY'S REPORT.

Arising out of the minutes of the last meeting, I have to report that I have investigated the position of all of the old recipients, and now recommend that the grant be continued to Mesdames B—, Y—, G—, G—, B—, C—, J—, T—, S—, P—, and M—.

Further investigations have been made referring to Mrs. R— and Miss H—, and I place the communications before you. Also the further correspondence with reference to Mrs. W—, and suggest that the grant in this case be increased to 10/- per week.

A fresh application has been received from Miss B—, since the receipt of which the Benevolent and Mutual Defence has made her a grant of 5/- per week for twelve months. A cheque for £1 has been sent for immediate relief.

A grant of £2 was made to the widow of the late Inkerman Drake, who died recently in great distress, to assist her in funeral and other expenses.

I have had correspondence from Mr. P. J. Simpson, referring to his kind donation of over £70. As no immediate opportunity occurs for carrying out his wishes to use the money for educational purposes, he has consented to the investment of the sum. This has been invested coupled with donations on hand. Advised by my co-trustees, Sir Stewart Stockman, and Mr. Garnett, we have been able to purchase £137 worth of 3½ per cent. Western Australia 1920-35 stock.

In presenting my list of new members I would call your attention to the handsome subscription of £5 5s.

from the Natal Veterinary Medical Association. I hope we may be able at the annual meeting to suggest some scheme by means of which we may have representatives in the Colonies.

With the approval of the President, extra grants at Xmas have been made to those widows who have children, the sum varying from £2 10s. to a widow with seven children, and £1 in the case of small families. This sum has, however, been amply met by donations received from friends in response to our President's Christmas appeal. As in previous years the sum of £2 each has been entrusted to two members of the profession to be expended for the comfort of our two old-age pensioners. I have no doubt you will approve that we have done everything we can with our small income to make Christmas a happy time for our old people, and the little children of our poor widows.

I am unable to present my balance-sheet, which, however, is not due until May. Roughly we have received—subscriptions £255, interest £96. Total £351. Our expenditure for relief has been £348, and for incidental expenses £22, making a total of £370. We have, therefore, overspent our income by approximately £20. If we could enrol more new subscribers we could raise our grants in practically every case to 10s. per week, otherwise this will not be possible for some time to come, though I am still hoping that we shall achieve it.

It is a matter of very great regret to me that we have sixteen outstanding subscriptions unpaid. I feel sure through inadvertence. I should, however, be glad if our subscribers would remember that I am only a struggling provincial veterinary practitioner, and the delay entails the expenditure of endless postage and extra work I can ill afford to give the time to. I should add I have four votes in the name of the Fund for the next election of the London Orphanage Asylum.

It was decided to discontinue the grants to Mrs. R. and Miss H.

The grants to all of the old recipients were again considered, and it was unanimously decided to continue the remaining grants for three months pending further consideration.

The SECRETARY was instructed to write a letter to the Natal Veterinary Medical Association suggesting the formation of a local Colonial Sub-committee to forward the objects of the Fund.

*New Subscriptions and Donations received since
October last.*

W. SHIPLEY, Hon. Sec.

NORFOLK

VETERINARY INSPECTORS ASSOCIATION.

The annual meeting took place at Norwich on Jan. 24th.

The SECRETARY first presented his report and balance sheet for 1913, the latter showing a deficit of £1 9s. 8d. Subsequently it was decided to make a levy of 1/6 per member as well as the annual subscription of 2/6 to make up for the deficiency.

The following officers were elected for the ensuing year :—

President. W. SHIPLEY, Esq.

Committee. Messrs. LOW, HOLL, BANHAM, and STANDLEY.

Hon. Secretary. WILFRID WATERS, Blofield.

W. WATERS, Hon. Sec.

DISEASES OF ANIMALS ACTS, 1894 to 1911.

Return showing the number of Premises on which the existence of TUBERCULOSIS has been notified to the Board of Agriculture and Fisheries during the month of January, 1914.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Feb. 2, 1914.
NOTE.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

The Outbreak of Foot-and-Mouth.

The Board of Agriculture and Fisheries received information on Saturday, 31st Jan., that an outbreak of foot-and-mouth disease had been confirmed near Naas, County Kildare, Ireland, by the Department of Agriculture and Technical Instruction for Ireland. Further, that the Irish Department were scheduling an area of approximately 15 miles radius round the infected farm, and would proceed with the slaughter of the animals thereon. As a preliminary measure that Department had also instructed their Port Inspectors to allow no shipments of animals to Great Britain until further notice.

After considering the position the Board decided that the circumstances would warrant permission being given for the landing of animals for slaughter within the landing place from all ports in Ireland other than Dublin, from which port no shipments of animals could with safety be allowed for the present owing to the proximity of Dublin to the disease centre, and the trend of the trade from Kildare. An Order to this effect was issued the same afternoon, and arrangements were at once set on foot for tracing to their destination in Great Britain all animals that had been shipped to Great Britain from Dublin within the past fourteen days.

Fifteen cattle in one herd were found affected in the outbreak first reported. The cases were first diagnosed by two local veterinary surgeons. On Sunday morning a police telegram from Ballysax intimated that the disease had been detected amongst some pigs in that locality. Nineteen were at once ordered for slaughter, as were all sheep and cattle on the farm.

One serious result of the outbreak is the postponement of the show and sale of pure-bred bulls under the auspices of the Royal Dublin Society, at Ballsbridge, which was to take place Thursady, Feb. 5.

As yet the Department are unable to state how the disease originated.

No fresh cases of foot-and-mouth disease have been reported to the Irish Department of Agriculture from County Kildare, and the Department is confident that the measures adopted to check the spread of the disease have proved effective, and that it will be possible to keep it within the limits of the scheduled area.

Compensation under Tuberculosis Order.

At Loughborough County Court on Tuesday, January 20th, before his Honour Judge Wightman Wood, John Bull, farmer, Long Wharton, sued the Leicestershire County Council for £5 in respect of a cow which, it was alleged, was slaughtered by order of the Council's veterinary inspector under the Tuberculosis Order, 1913.

Mr. C. A. McCurdy, M.P., (instructed by Messrs. Clifford and Cliffords) was for plaintiff, and Mr. Wilfred Moss for the defence.

Mr. McCurdy said the questions to be determined would not be so much questions of fact, but depended on the consideration of somewhat unusual points of law. The Tuberculosis Order, 1913, gave local authorities power to inspect animals suspected of tuberculosis, and to condemn and pay compensation. Section 2 provided that if an owner had an animal he suspected, he was to

give notice to the local authority. Section 4 (1) provided that when the authority got the notice they should send a veterinary inspector to make an examination to see if tuberculosis existed. Section 4 (5) provided that the inspector was to report to the authority the result of his examination; and Section 5 (1) provided that when the inspector had reported, the authority was to give notice to the owner causing the animal to be slaughtered, but if the owner objected he had the right of appeal. The point of the last two sections was that it was not for the inspector to cause the animal to be slaughtered, but it was his duty to report to the local authority, who had to serve notice on the owner. Section 6 provided that if the animal was slaughtered the value was to be agreed upon, and under Section 7 the carcase had to be examined by the veterinary inspector, who had to give the authority a certificate of the result. Section 8 provided as to the compensation.

The County Council issued to farmers a general notice purporting to give information as to the provisions of the Order, but omitting altogether the provisions of Sections 4 (5) and 5 (1), so that the procedure under the Act appeared to be that the inspector was to inspect and cause to be slaughtered, and that after slaughter compensation would become payable. The circular did not suggest that the inspector had to report to the local authority.

The facts were that this Order came into force on May 1, and on June 9 plaintiff, who had received a copy of the notice, was in doubt as to whether a cow that was very emaciated might not be suffering from tuberculosis. He first spoke to Mr. Porter, a member of the County Council, and in consequence of his conversation he gave notice in pursuance of Section 2, to the police. Then he received a postcard that Mr. Parr, the County Council's veterinary inspector, would call. Mr. Parr called on June 12, when plaintiff was not at home, and saw his son Richard. Mr. Parr made no physical examination, but looked at the cow and said there was no doubt what it was suffering from. He then asked Richard Bull what they generally did in the case of screws, and Bull said they sent them to a knacker named Blankley. Mr. Parr asked if he thought they would get 30s. from Blankley, and when Bull said he thought they would, he said they had better send it to Blankley. This was reported to plaintiff, who sent the cow to Blankley, and it was slaughtered.

A postcard came from Mr. Parr asking if the cow had been slaughtered, and later he made a post-mortem examination, and found the cow entirely free from tuberculosis. When plaintiff applied to the County Council for £5 compensation, the answer was that the cow was not slaughtered by Mr. Parr's instruction, and therefore no compensation was payable. Subsequently Mr. Parr told plaintiff it was a mutual understanding between him and the son that the cow should be slaughtered, and not an order.

The grounds on which Mr. McCurdy submitted plaintiff was entitled to recover was that Mr. Parr went to the farm with his assistant in a purely official capacity for the express purpose of pronouncing on the condition of the cow. Under those circumstances a farmer would, of course, consider he was bound to attach the greatest importance to his statement. Plaintiff was, therefore, entitled to regard the conversation as amounting to an order to have the cow destroyed. But even assuming that it was not an official order, and merely a mutual agreement, Mr. McCurdy submitted that the statement that there was no doubt as to what the animal was suffering from amounted to a warranty, which became a term of the agreement. The County Council had, in fact, abbreviated the procedure under the order for their own convenience, and if in this abbreviated procedure they made a mistake plaintiff ought not to be in

a worse position than if the full procedure had been gone through.

Evidence on the facts as stated by council was given by plaintiff, who said he gave £17 for the pair of heifers, of which this was one. Blankley gave him 20s. The cow was not valued before slaughter. Witness said he had read the circular through carefully. He considered the animal was worth £8, but Mr. Porter asked him to make the claim as low as he could, and that was why he claimed £5.

His Honour: To save the ratepayers?

Richard Bull, plaintiff's son, said Mr. Parr told him there was no need to examine the cow, as it was certain she had got tuberculosis. He gave witness his visiting card to send to Blankley for him to let Mr. Parr know when the animal was killed, so that he could examine it. Witness denied that he told the inspector it would have been killed if it had not been for the order. He told witness it would cost a lot to have it tested, and it would be cheaper to have it killed.

William Edge Porter, farmer, Dishley, a member of the County Council and of the committee administering the Tuberculosis Order, said they found the cost of carrying through the procedure of the Order was very heavy, probably £5 for each beast. The inspector, Mr. Parr, had from time to time reported that he had been able to make friendly arrangements with farmers in the case of suspected beasts that the animals should be slaughtered without going through the expensive procedure of the Order.

Mr. Moss said it was a rather remarkable position for the witness to be giving evidence against the body of which he was a member, and disclosing matters of privilege.

Mr. McCurdy said it was a question of authority. The second ground of claim was that acting with the authority of the Council Mr. Parr had entered into an agreement to abbreviate the procedure to dispense with the expensive valuation before slaughter.

Witness added that Mr. Parr had authority to make such arrangements, and had done so in many cases.

Fred Blankley, slaughterer, Loughborough, said he did not consider there was anything the matter with the cow when he slaughtered it. It went to London.

Mr. Moss: Why did you sell her for cats' meat if there was nothing the matter with her?

Witness: I was told to kill her.

Mr. Moss submitted that the conversation with Mr. Parr was not to be construed as an order, and that he never made any statement as to what the animal was suffering from. It was clear from clause 6 of the circular that before slaughter there was to be agreement as to the value, or failing agreement, the value was to be ascertained. No matter what misleading message plaintiff's son gave to his father, for which the defendant's were not responsible, Mr. Bull ought to have known that there must be agreement as to value before slaughter, and there having been no such agreement, there must have been doubt whether the order was being put in operation. The practice of arrangement with farmers for slaughter was adopted in other counties, and was approved by the Board of Agriculture. The objects of the Order were attained if the farmer did away with the beast himself, and it gave the farmer the opportunity of getting rather more for an animal than if it was dealt with under the Order.

John Geo. Parr, consulting inspector to the County Council, said when he saw the cow he said it was in a shocking state, but he never said it was suffering from tuberculosis. He explained the order to young Bull, and said if he could make more than 30s. for the animal he was at liberty to have it killed and make what he could. Witness also said he would like to make a post-

mortem so as to know what was the matter with the cow.

Richard C. Moore, assistant to the last witness, said he made a post-mortem examination, and found the cow had suffered from a disease of the bowels which was bound to prove fatal. There was no tuberculosis.

JUDGMENT.

His Honour said the procedure under the Order involved a great deal of trouble and expense, and in the interests both of the farmers and ratepayers the County Council desired to make arrangements which would obviate the expense. It was the duty of Mr. Parr, if he could, to avoid the expensive processes of the Order, and that put him in the position of a person skating on thin ice. He might have brought it very clearly to the knowledge of the persons on the farm, and might have thought he was doing so, but he rather overlooked the fact that he was not talking to a veterinary surgeon, or a medical man, or even a lawyer, and not even to the farmer, but to his son, and the question was what was the effect made upon that man's mind by what was said. He had come to the conclusion, his Honour said, that the impression left on the son was that the opinion of the veterinary inspector was that the report his father had made that he believed he had a tuberculous animal, was correct, and it was necessary it should be slaughtered, and that in effect he was receiving a direction from the inspector that the animal was to be slaughtered. He (the Judge) could understand the distinction in Mr. Parr's mind between carrying out the Order and making an arrangement outside the Order, but he did not think he sufficiently brought that home to the young man. What was said was taken to be a representation that in the opinion of the inspector the animal was tuberculous and must be slaughtered. That representation was unintentional, but the farmer acted upon it, and to his disadvantage, and therefore he was entitled to succeed in the action. But as to the damages, his Honour continued, he accepted the evidence that the animal was in a shocking state, and that its value was very small. But it was bought and killed and sent away under the idea that it was tuberculous, which it was not. Diseased as it was, it would have fetched more than it did if it had not been sold as tuberculous. Plaintiff had received £1, which must be credited, and judgment would be for £2 2s.

On Mr. McCurdy's application, costs were entered on a higher scale.

Purchase of Army Horses.

The following official statement was issued by the War Office at the end of last week:—

The Secretary of the War Office wishes to correct certain notices which have recently appeared in the Press, stating that the Army Remount Department is under reorganisation, and professing to give particulars as to the numbers of officers about to be appointed to act as district remount officers. A separate department for horse purchase is not being organised. This work will continue to be carried on by special officers, and on the lines hitherto followed, except that, in order to satisfy a demand that purchases should be made direct from breeders, it is in contemplation to send officers to suitable localities on advertised dates, to see such horses as may be offered, and purchase those that are suitable.

For the purposes of the military horse census of the United Kingdom, it is proposed to employ district remount officers in place of adjutants of Territorial units as hitherto. Not more than eighty-five such officers would be appointed, and selections to fill all the vacancies have already been made provisionally, and there is a long supplementary list of qualified applicants.

Royal College of Veterinary Surgeons.

FELLOWSHIP DEGREE.

A meeting of the Board of Examiners for the Fellowship Degree was held at the College, 10 Red Lion Square, W.C., on Saturday, Jan. 31st, 1914. The following is a list of the successful candidates, together with the titles of their respective Theses:

- RICHARD FINCH,
"Milk: Its Diseases and Contaminations."
S. J. MOTTON, "The Surgical Sequelæ of Parturition in the Mare and Cow."
W. T. BROOKES, "The Ante-mortem and Post-mortem diagnosis of Bovine Tuberculosis."
Capt. G. B. C. REES-MOGG,
"Ovariectomy of the Domesticated Animals."
CHARLES HARTLEY, jun.,
"Bier's Hyperæmia in Veterinary Practice."

The Examiners were Prof. J. Macqueen, Messrs. J. Malcolm and W. Woods; Mr. W. J. Mulvey in the chair.

FRED BULLOCK, Secretary.

The Shetland Sheep Dog.

The tiny ponies of Shetland are world-famous; but there is a variety of dog which is also indigenous to the island. The Shetland dog is really a collie, and it was originally known by that name, but when during the "fancy" progress of the breed it was desired to register it at the Kennel Club, fanciers of the large collie rose up in arms against any other breed being known as a collie, even with the distinctive adjective of "Shetland." A compromise was then come to, and the breed is now known as the Shetland sheep-dog. Two specialist clubs look after its interest—The Shetland Sheep-dog Club, with its headquarters in Lerwick, and the Scottish Shetland Sheep-dog, the secretary of which resides in Dundee. It seemed that until recently the Shetland sheep-dog was in danger of being ruined as a popular fancy animal by a restriction in the standard of the clubs, which said that the height of this canine "must not exceed twelve inches." This was leading to the dog being bred so small as to be useless for anything but a lap dog. Lately, however, a new standard was drawn up, which says that the ideal height is twelve inches, thus doing away with the maximum. The Shetland sheep-dog has any amount of pluck, and though primarily intended for herding small sheep, is quite useful for working cattle and sheep of the ordinary standard sizes. It is found in all the recognised collie colours.

Personal.

Mr. H. SMITH, M.R.C.V.S., of Worthing, was returning from Durrington on Friday evening, 30th ult, with his groom, and on reaching the end of Shady Lane, facing Broadwater Green, they apparently failed to turn sharply enough to avoid the railings surrounding the Green, with the result that the horse pulled the trap over on to the turf, throwing both Mr. Smith and his man out on to the grass. Both Mr. Smith and his groom were badly shaken, and the latter had several nasty cuts on the face, but fortunately no bones were broken. A motor was obtained, and they were conveyed to their respective residences, where they were attended by Dr. Lockwood. The horse escaped practically uninjured, but the trap was badly damaged.

HATT—LAWRENCE.—On the 31st Jan., at St. Saviour's Walton Street, Upper Chelsea, by the Rev. W. Lawrence Waugh, Vicar of Chiseldon, Wilts., Richard W. Hatt, of East Ilsley, Berks., to Mary Emily, widow of Edward Lawrence, M.R.C.V.S., of Swindon and Badbury, Wick.

CORRESPONDENCE.

THE MOTOR TAXES.

Dear Sir,

Much has been written, and no doubt more has been thought of the mode of procedure to obtain recognition as medical practitioners and the privileges enjoyed by them, but nothing has been done. I suggest that every veterinary surgeon shall now send a letter of the nature of the one enclosed to his representative in Parliament, and on the principle of weight will tell, we should get beneficial results. This is a practical suggestion, and I shall be glad to hear a better course to adopt, but "Let's be up and doing."—Yours faithfully,

TOM. B. BINDLOSS.

[Copy.]

The Warren,
Long Sutton, Lincs.,
January 26th, 1914.

The Hon. F. McLaren, Esq., M.P.

Sir,—May I remind you that the Tuberculosis Order of 1913 has been in force for nearly twelve months, and when the report on the year's work is presented it will show that much has been done to terminate the sufferings of animals affected with "advanced tuberculosis," and thus have checked the spread of the disease.

As a natural sequence the risk of infection from animal to man has been lessened, and I think if you consider the matter you will agree with me in the opinion that this is a favourable opportunity for acknowledging the fact that veterinary surgeons, by reporting all cases coming under their notice, have been the principal means of securing the success of the Order.

May I suggest that you recognise these services by proposing or supporting a measure, extending to all members of the Royal College of Veterinary Surgeons those privileges respecting motor taxes, petrol rebate, and exemption from jury service now enjoyed by members of the Royal College of Surgeons and general medical practitioners. By so doing you will perform a gracious act of recognition of services rendered and somewhat recompense a profession seriously affected, financially, by the change from horse to motor traction.

Hoping that you will carefully consider the matter, I remain, sir, yours faithfully,

TOM. B. BINDLOSS, M.R.C.V.S.

PRESCRIPTIONS.

Sir,

The enclosed cutting from a weekly agricultural paper shows that we need be careful in giving details of treatment that we find successful.—Yours,
RUSTIC.

CANKER IN HORSES.—In your issue of December 26, 1913, I note "Canker in Horses." I have a cart mare, nine years old, with two hind feet which I should be very pleased to cure. Will you please send me the vet's address that I may write to him?—W.

[*.* If you wish to try the special treatment that he recommends in *The Veterinary Record* of November 29, 1913, you must put the case into your veterinary surgeon's hands, as the writer refuses to answer any particulars except from a qualified veterinary surgeon. He also says that canker is a disease which requires expert treatment, and he is unwilling to publish his methods, as he considers veterinary surgeons only are capable of properly carrying out the treatment. I have asked permission to publish them, but he refuses it. If you do not care to put the matter into the hands of a vet., write me fully as to the extent and duration of the disease and the remedies tried, and I will advise the best treatment to try. Sorry we cannot reply by post. —WENTWORTH.]
Farm, Field, and Fireside.

VOL. XXVI.

UNQUALIFIED OPPOSITION.

The "Registered Existing Practitioners," whose opposition was so formidable to us thirty years ago, are now rapidly dying out. Roughly speaking, at one time there was about one registered man to every three qualified ones: to-day the proportion is only about one to seventeen. The number of registered men remaining on the list is now little more than 200; and, as it is certain that not a few have retired from practice, the number in actual work may be confidently set down as something well under 200. All produced evidence of having been in practice since 1876, so their decrease must soon become more rapid. Ten years hence few will be left in active practice, and their opposition will be hardly worth mentioning.

On the other hand, most experienced practitioners will agree that opposition from men who are not even registered is on the increase. These men are a heterogeneous body; and a long essay would be necessary to analyse the different classes and their sources, and to consider the methods of dealing with them. At present we can only touch upon one or two points.

We cannot hope to exterminate unqualified practitioners legally—the law will never do more than prevent them from assuming our title. We may do something to limit their numbers and their effectiveness; our Council's recent decision to suppress the employment of unqualified assistants by veterinary surgeons will ultimately have much effect in this direction. Very many of the most successful unqualified practitioners, including many registered men, were originally unqualified assistants, and the Council's action will deprive such men of their best training ground. The effect will not be very perceptible for a long time, but so many living qualified men have helped to manufacture the present unqualified opposition that we have little right to be impatient.

Again, there are directions in which we might do more to meet unqualified men on their own ground. Castration, especially of farm stock, is largely left to unqualified men—in many districts a veterinary surgeon willing to do it can hardly be found. Consequently, castrators are more common than need be; they usually attempt general practice, and they find endless opportunities of winning over the actual clients of veterinary surgeons. Castration is neither pleasant nor in itself very lucrative work, but there are many districts in which a member ready to do it may easily transform a poor practice into a good one.

A fuller examination of the subject will show many points in which we ourselves have been, at least, a little at fault.

FRACTURE OF INCISOR TEETH IN THE HORSE.

The necessity for removal of the permanent incisors occurs but seldom. It is a peculiarly satisfactory operation inasmuch as it is one of the few equine dental procedures in which one can, with safety to the patient, use a general anaesthetic. The following may be of interest:—

History. A cavalry horse during an exercise was kicked in the mouth by another horse, causing an incomplete transverse fracture of the upper central incisors close to the alveolar margin, and exposing the pulp. The teeth were driven back towards the roof of the mouth. The lips were not involved in the injury. Extraction was decided upon.

Operation. The animal in the recumbent position was anaesthetised. The chloroform muzzle being removed, a roll of absorbent wool with its ends well projected was placed across the bars of the mouth to soak up blood and dressing. The jaws were then fixed by winding a webbing around the muzzle. Having cleansed the surgical area, the head was propped up with the usual straw-stuffed sack, and the operation commenced. The gum and mucous membrane was removed as far back as was necessary, and the periosteum scraped away with a curette. The anterior alveolar plates of the two teeth were then cut out with a $\frac{1}{2}$ in. cold chisel exposing the whole length of the fangs; prising up the teeth thus exposed was simple. It only remained to trim and smooth the sides of the sockets and the alveolar septum, snip off the fragments of mucous membrane, flush out with warm 1-1000 Potass. perm. sol., and the task was completed.

It is to be noted in passing that the use of extraction forceps for the permanent incisor teeth of any but very old horses is laborious, and the effort may even prove futile.

The complacency of the animal in this case, both before and after the operation was striking. He was not troubled, as is the unfortunate human in similar circumstances, by the thoughts of æsthetic dentistry to come.

I am indebted to M. Louis A. Merillat's "Animal Dentistry" for the simple and concise description contained therein of this operation.

J. R. HODGKINS. F.R.C.V.S., Capt. A.V.C.

Dublin.

THE TREATMENT OF EPIZOOTIC ABORTION IN LARGE HERDS.

In acknowledging the numerous communications I have received in reference to my article on "Epizootic abortion in dairy herds," which was published in *The Veterinary Record*, Oct. 4th, 1913, I can assure my correspondents that it will be a duty and a pleasure for me to supply, as far as my ability will enable me, all the information which has been asked for.

The lines of treatment suggested in my article are only suitable for extensive outbreaks of epizootic abortion in dairy herds, and are too expensive for single cases on dairy farms.

In reference to the leading questions, the following are my suggestions:—

(1) "I have always removed the placenta mechanically, but if there is a better way, I should like to know?"

For eight years I was engaged single-handed in one of the largest cattle practices in the world, and certainly the largest in Australia. These were my methods:—

If the case was only a short distance from my headquarters, after removing the foetus, the uterus was irrigated with a bucketful of warm water (about 100° F. to which was added a small quantity of Tincture of iodine. A large funnel and six feet of $\frac{3}{4}$ -in. rubber hose form a necessary part of the outfit required in a cattle practice. The addition of iodine has a twofold object, (1) it is a good antiseptic, (2) it prevents the cow eating the placenta, thereby removing all doubt that the afterbirth has been expelled. A dairyman having a herd of over 100 cows cannot afford the time to note if the newly-calved cow has expelled the placenta or not.

In cases a long distance from headquarters the afterbirth should be removed after the delivery of the foetus, this obviates all risk of having to make a second visit to the recently calved cow.

(2) "How long after parturition do you use the irrigation for retained placenta?" In the summer one day. In the winter two to three days.

(3) "How often do you irrigate to remove a retained placenta?"

In such cases I fill the uterus with a hot aqueous solution of 1 per cent. carbonate of soda, commercial, i.e., washing soda. This loosens up the membranes, and by its weight causes the cow to exert an expulsive effort. In the majority of such cases all the membranes come away at once; provided there is no decomposition of the placenta, no further treatment is required. Should the membranes be retained after such an irrigation of the uterine cavity, it is to be anticipated that they are retained through being wound round the maternal cotyledons, or adherent to the walls of the uterus. The correct procedure in such cases is to remove the retained placenta by mechanical means, bearing in mind that the first principle is that the maternal cotyledons must not be injured, lest there be absorption of sepsis which may accompany such cases.

In the removal of the placenta from the uterine walls, the fingers and short finger nails only should be used, no surgical instruments are admissible; should the membranes be wound round the maternal cotyledons great care should be exercised, and they should be removed in the manner which one exerts in undoing a button of a garment. Should there be a septic condition of the contents of the uterus, before their removal liberal irrigation with hot water and iodine should be adopted. After the membranes are removed another flushing is required; if the uterus has lost its tone, and does not expel the contents, it is necessary to use the hose as a syphon, and remove all the fluid from the uterine cavity with a clean sponge. If the first manipulation is done in a thorough manner further exploration

is not necessary; flushing with hot water and iodine once a day is all that is required until the uterus is in a normal condition. Under such conditions the following must be remembered:

The long limb of the hose, when using as a syphon, should be filled with solution before the short limb is placed in the uterus.

The hose requires to be guided by the hand when entering the os uteri.

Clean hands and arms are necessary in such manipulation. Although the uterus and the membranes are in a septic condition it is not necessary to add a new strain of micro-organisms by hands and arms which are not clean enough to be beyond suspicion.

Cuts and scratches of the hands and arms should be treated with liniment of iodine. Many obstetricians in veterinary practice have regretted not adopting this necessary precaution.

When called in to treat a cow, in my outfit are a 6ft. length of three-quarter inch rubber hose, a funnel, a light hard wood mouth gag with a hole in its middle large enough to pass the hose through, and a blocked saline purge. If the cow requires a purge, the blocked saline purgative powder is added to three-quarters of a bucket of hot water and well stirred, the mouth gag is fixed in the mouth by means of a strap with buckles on both sides placed behind the horns and ears, while straps over the nose and under the lower jaw keep it in position. The end of the hose is passed through the hole in the gag to the back of the mouth, then gently pushing it into the oesophagus, making sure that it has not entered the trachea by feeling its passage along the jugular furrow on the left hand side of the neck, then pass into the entrance of the rumen. An eructation of gas will be an indication that the hose has entered the rumen. The hose in position, fix the funnel in the other end and pour in the contents of the bucket from an elevated position, i.e. by standing on a box. The same hose and funnel can be used for the irrigation of wounds, flushing out the uterus, the administration of rectal injections, as a syphon to remove fluids used in flushing out the uterus, and for irrigating and syphoning medicated solution from the stomach in cases of poisoning.

J. DESMOND, V.S.

Adelaide, South Australia.

ABSTRACTS FROM FOREIGN JOURNALS.

POISONING OF CATTLE BY INSECT BITES.

In the district of Neustadt, Hanover, in the season of pasturage of the year 1911, numerous cases of illness in cattle occurred as a consequence of the bites of the fly *Simulium ornatum*.

The affected animals suddenly refused food, and showed a tottering gait. Soft painful swellings, warmer than the surrounding tissues, appeared upon the throat, neck, udder, and the inner surfaces of the thighs. In some cases, a bloody nasal discharge was seen. Out of 60 cases, 33 were fatal. Some animals died after only one or two hours' illness, others not till after from twenty-four to thirty-six hours.

Post-mortem examination showed well-marked saturation of the skin subcutis, punctiform hæmorrhages in the muscles (which were black-red in colour), serous effusions in the pleural and peritoneal cavities and in the pericardium, punctiform hæmorrhages under the parietal pleura and peri-

toneum, and upon the endocardium and epicardium, and an opaque appearance of the liver and kidneys. The spleen was either unaltered or swollen. The cardiac muscle was black-red in colour, and punctiform hæmorrhages were seen in it. The ventricles were tensely filled with black-red and imperfectly coagulated blood.

In animals that were slaughtered *in extremis*, the flesh quickly changed colour, became dark to blackness, assumed a watery condition, and putrefied easily. Prophylactically, the parts of the animals' bodies where the hairs were scanty were wetted with a mixed aqueous solution of lysol, creolin, and alum. The treatment adopted in the case of animals already affected was the administration of cardiac stimulants in the form of coffee, rum, or cognac, or the subcutaneous injection of caffeine.—(*Münch. Tier. Woch.*)

[Neumann mentions several species of *Simulium*, and names two in particular—*S. maculatum* and *S. columbatzense*—as having caused fatalities in stock. He does not refer to *S. ornatum*—or, at least, not under that name. *S. ornatum*, with several other species of *Simulium*, is found in this country; and Fleming found *S. Reptans* exceedingly troublesome to horses during manœuvres in Staffordshire. According to Laboulbène, the various species of *Simulium* are somewhat difficult to distinguish from one another.—*Transl.*]

THE TOXIN CONTAINED IN THE ASCARIS MEGALOCEPHALA.

M. Weinberg, of the Pasteur Institute, and A. Julien, of the Veterinary Sanitary Service of the Seine, have been working upon this subject for two years, and state their results in a long article. After pointing out the numerous instances in which the handling and dissection of ascarides has caused toxic effects in human beings, they proceed to consider the toxicity of the ascaridian secretion for the small animals of the laboratory. On this point different investigators have reached opposite opinions, but the authors, having collected the peri-enteric liquid by a special method of their own which they describe, have satisfied themselves that it is toxic, and lethally so, for such animals as guinea-pigs. The degree of toxicity, however, varies in different samples of freshly obtained peri-enteric liquid.

Further, the authors have investigated the effect of the ascaridian toxin upon the actual host of the parasite by instilling the peri-enteric liquid of the *Ascaris megalocephala* into the conjunctival sac of the horse, and have also endeavoured to elucidate the nature of the toxin or toxins contained in the liquid. They report their results with considerable detail, and their main conclusions may be summarised as follows:

1. The peri-enteric liquid of the *Ascaris megalocephala* is injurious not only to the animals of the laboratory, but also to the horse himself. The ascaris therefore secretes a veritable toxin.

2. Instilled into the eye of the horse, the ascaridian toxin, in two-thirds of the cases, causes a local reaction characterised by œdema of the eyelids, congestion of the conjunctiva, and lachrymation.

3. Sometimes this local reaction is accompanied by more serious symptoms, such as dyspnœa, diarrhœa, and profuse sweating.

4. The ocular reaction appears very quickly, and only persists for from twelve to twenty-four hours. The general symptoms, though sometimes very alarming, disappear at the end of from two to three hours. (These serious general symptoms are most frequently observed in thin and debilitated horses, but this is only a general and not an invariable rule.)

5. The action of the toxin varies greatly with the samples of peri-enteric liquid collected. It may cause ocular symptoms even when the toxin is diluted up to 1 in 5000.

6. The peri-enteric liquid owes its toxic effect to a series of active substances, not to one alone.

7. The toxin is thermostable, traverses the Chamberland filter, and is partially dissolved in alcohol and ether. Its volatile products are also toxic.

8. Horses infested by ascarides gradually become immunised against the action of the toxin secreted by the parasites. In such horses the instillation of peri-enteric liquid does not in general provoke ocular reaction.

9. The serum of horses infested by ascarides contains specific anti-bodies, which are capable of neutralising very weak dilutions of the ascaridian toxin *in vitro*.

10. Among the other intestinal parasites of the horse, the sclerostomes alone secrete a substance capable of provoking an ocular reaction. This reaction is less frequent and more feeble than that caused by the peri-enteric liquid of the ascaris.—*L'Hygiène de la Viande et du Lait*.

CENTRAL HEMIPLEGIA IN A HORSE.

Busch records (*Zeitschr. für Veterinärkunde*) the case of a horse which he was called to treat, and found showing the following symptoms. The tongue was hanging a hand's breadth out of the left corner of the mouth, and the left under lip hung loosely downwards. The upper lip and the tip of the nose were twisted to the right, thereby narrowing, lengthening, and lowering the left nostril. The left ear was hanging loosely and horizontally downwards, and could not be moved. The eyelids of the left eye were unable to close, and the upper one had sunk downwards. The head was turned obliquely to the right. In consequence of the narrowing of the left nostril, the breathing was rendered rather difficult. The pulse was 48 per minute, and the rectal temperature was 100° F. Shortly cut food was taken up with the incisor teeth, but a great deal of it fell out of the mouth, covered with saliva, during mastication. The horse could take water, and in doing so immersed the head up to the corners of the mouth.

When standing in the stall the patient pushed the left side of the head against the edge of the manger, and leaned with the same side of the body against the wall. It could only be led out of the stall when turned towards the left, and pushed and supported by several people.

The gait in progression was uncertain, the limbs on the left side being brought forward with a dragging movement, and placed on the ground as if groping. In movement, the horse pressed strongly to the left, and rolled in every direction during turning. The left eye showed marked dimness and opacity of the cornea, and the conjunctiva was very much reddened and swollen.

The symptoms of paralysis increased in the course of a few days, so that the horse could scarcely stand upright. It was therefore put into slings. The next day it showed symptoms of great agitation, pressed with the raised head against the manger and then backwards, thereby slipping out of the slings. It then fell to the ground, and could not again be brought to the standing position. Water was still taken, but not food. The temperature was now 99.1° F., and the pulse 50 per minute.

After three days the horse rose, shook itself, took hay, and could stand. The symptoms of pushing with the head, leaning against the wall, and the above described abnormal progression, were no longer seen, but the oblique carriage of the head and the deportment of the tongue and upper lip remained, and the lower lip still hung loosely downwards. An ulcer was now present in the middle of the cornea of the left eye. The horse received soft food and hay. The condition improved, and after three and a half months the symptoms of paralysis had dwindled to an insignificant hanging downwards of the lower lip.

The author briefly sketches the therapeutic treatment adopted. The muscles of the ear and face were massaged daily. For a fortnight the horse daily received an injection of strychnine, and in the third and fourth weeks injections of veratrin. In the latter course of the case electricity was applied daily.

The author suspects that the cause of the condition was a blow or push with the head against the manger or the wall of the stall, which was a very narrow one.—(*Münchener Tier. Woch.*)

BOTS AS A CAUSE OF COLIC.

Seegert records (*Zeitschr. für Vet.*) the following case. A horse, which had been at grass during the previous summer, suffered from irregularly intermittent attacks of colic. The action of the bowels was good, despite the liability to colic. Seegert suspected bots as the cause of the trouble. He therefore gave, three times at intervals of two hours, two gelatine-capsuled balls each containing 8 grammes (= 3ij.) of bisulphide of carbon, and followed this up by giving 25 grammes of extract of aloes a few hours after the last couple of carbon bisulphide balls. On the second day pulpy evacuations set in, in which over 200 bots were counted. From that time forth the horse was healthy.—(*Berliner Tier. Woch.*)

W. R. C.

[Cause and effect seem so plain here that the case appears to be worth noting as a contribution to a very old question.—*Transl.*]

WEST OF SCOTLAND VETERINARY MEDICAL ASSOCIATION. [NATIONAL V.M.A.—SCOTTISH BRANCH].

The annual general meeting was held at the Glasgow Veterinary College on Wednesday, 14th January, at 3.30 p.m. In the unavoidable absence of the President, Mr. Thos. A. Douglas, M.R.C.V.S., Kilmarnock, presided. The following members were present: Messrs. Hugh Begg, Hamilton; McGeoch, Paisley; John Taylor, Cathkin; Jas. F. Taylor, Hamilton; J. G. Reynard, Perth; Geo. W. Weir, Glasgow; Jas. F. Macintyre.

Apologies for absence were intimated from the President: Prof. J. R. McCall, Messrs. Jas. Macfarlane and R. G. Anderson.

On the motion of Mr. Begg, it was agreed to accept the minutes of the previous meeting as read.

Election of Officers.—The present office-bearers were elected for another year, viz.: *President*, Prof. J. R. McCall; *Treasurer*, Mr. Geo. W. Weir; *Secretary*, Mr. Jas. F. Macintyre.

Correspondence. The SECRETARY read a letter from the Secretary of the Royal Sanitary Institute intimating that the Institute would hold a Congress at Blackpool on July 6th-11th, 1914, and asking that delegates be nominated from this Association to attend.

Mr. JOHN TAYLOR (Cathkin) proposed that this matter be left over till next meeting, and this was carried unanimously.

A letter from Mr. W. Shipley, F.R.C.V.S., Hon. Sec. and Treasurer of the Victoria Veterinary Benevolent Fund asking that the question of a subscription to this Fund be introduced.

Mr. REYNARD proposed that a guinea be sent to the Benevolent Fund, and this was seconded by Mr. Weir.

A letter from Mr. Henry Gray, 23 Upper Phillimore Place, London, W., Hon. Sec. and Treasurer to the "Hunting Memorial Fund." On the termination of the reading of this letter, sympathetic references to the death of the late Mr. William Hunting were made by the Chairman and Mr. Begg. On the motion of the latter gentleman, seconded by Mr. Reynard, it was agreed to forward a sum of two guineas to the Hunting Fund.

The TREASURER read a letter from Prof. Bradley Principal of the Royal (Dick) Veterinary College, Edinburgh, referring to the position of this Association in relation to the National Veterinary Association, in which he indicated that for every member of this Association who pays his subscription, our Treasurer pays to the Secretary or Treasurer of the National a capitation fee of 1s. Prof. Bradley further added that every member for whom we paid a capitation fee may become a member of the National on payment of an annual subscription of 7s. 6d.

On the motion of Mr. Begg, seconded by Mr. Douglas, it was agreed to leave this matter in the hands of a committee composed of the President, Treasurer and Secretary, to decide the annual fee to this Association in its relation to the National.

A meeting was held later by this committee, when it was decided that 10s. 6d. be the annual subscription to this Association.

THE TUBERCULOSIS ORDER, 1913.—ADJOURNED DISCUSSION.

Mr. TAYLOR said that in opening this discussion on the subject of the Tuberculosis Order, he did not think he could give anything new about it. Mr. Douglas had given them some insight into the working of the Order by an inspector, and he would suggest that he might take up the Order as it affected the private practitioner. He thought that general practitioners were more or less

in favour of the Order, and he thought he was right in saying that they wanted the working of it to be a success.

Mr. Douglas had remarked in the opening part of his paper that tuberculosis had for many years been giving all concerned a good deal of worry; meetings had been held, papers read, and discussions had taken place, commissions had been appointed, reports issued, but not much had been done to eradicate the disease from amongst our stocks. Now the Board of Agriculture had moved, and issued an Order. However small some of us may think that Order is, it is hoped that it may be only the thin edge of the wedge, and if proper use is made of it and good results are seen to come from its enforcement, we may expect to find the Order altered, and amended so as to tackle tuberculosis in a more thorough manner.

Mr. Douglas says the Order is a very gentle beginning, the object being to get rid of two of the most dangerous classes of tubercular animals. Will this be the case? If we look at it from another side, take the clinically affected animal, an animal we are certain by clinical examination is affected by tuberculosis, if in fair condition and udder free from any induration and giving plenty of milk, she is allowed to keep her place in the byre—she does not come under the Order—and the result is that she is contaminating the whole surroundings. Animals standing with her, if predisposed to the disease, become affected, the milk drawn from the other cows is polluted by tubercle bacilli and the disease is spread broadcast, seeds are sown which produce a new crop of udder affected and emaciated animals, thus helping to frustrate the good effect we expected to derive from the Order. But if we had the clinically affected cow included under the Order and compensation given for her, then the emaciated animal would disappear, for if found, the owner might be prosecuted for keeping her. Mr. Douglas in his paper notes this clinically affected animal, but a passing note is not of much good, all having public health and the health of our stocks at heart, must bestir themselves and approach the Board of Agriculture asking for an extension of the Order. Want of money will be the excuse, but money can be got for other objects and it can be got for this. The £60,000 allowed for removing the emaciated cows would be better spent in compensating for the clinically affected animal, for if spent thus the "piner" would disappear.

With Mr. Douglas in his definition of emaciation I am afraid I cannot agree. His opinion appears to be that if an animal is leaner, and not in the same condition as her neighbours in the same stock, he would hold that she is an emaciated animal; but take that animal and place her in another stock not so well cared for, there she may be the best-looking animal in that stock. This animal, in my opinion, comes under the class "clinically affected," not "emaciated." The reading of the Order is emaciation, a "piner," an animal worth knacker's price, no more.

As to valuation, Mr. Douglas and I are at one, there should be no difficulty here. It does not matter what the animal cost your client. If the animal develops a disease then her value is diseased value. If a cow, and she develops localised tuberculosis in the udder, with the carcass free, she is no use for milk, she is passed on to the butcher, so that her value here is not the value of a milk cow but of one for meat, "butcher's value." If she develops generalised tuberculosis with emaciation, then her value is knacker's value. But this is a matter which can safely be left in the hands of the inspectors, they will do the best they can for their local authority, and we can advise our clients to do the best they can for themselves.

With regard to diagnosis, as I stated at the previous meeting, there may be a difficulty here in the private

practitioner coming to a correct diagnosis, but if we have a case of emaciation and we can find no other cause for it, we are safe in reporting the animal under the Order, knowing that 90% of the emaciated animals we come across are tuberculous.

A more difficult problem arises when we come to udder diseases. The Order says all animals with tuberculosis of the udder, indurated udders, and any other chronic disease of the udder are to be reported under the Order. Here your client is liable to be prosecuted for keeping a cow with tuberculosis of the udder in his stock, unless you advise him correctly. If he is caught he throws the blame on you, but I think a little common sense here will save a lot of trouble. When we are consulted about an udder affection, if there is any suspicion that tubercle may be present, advise your client to report under the Order, it costs him nothing and it keeps him safe.

There is another side of this story. All the cases of induration you report to the inspector are noted in printed forms, and opposite each report you find the result of the inspector's investigation. Well, you don't care to see "negative" put against nearly every report you send in, and if the report is examined by some of the local authority, who may not know much about the subject, they are inclined to think this man does not know much about his profession, he has too many "negatives."

A good plan to detect tuberculosis of the udder would be for the practitioner to ask the inspector for a few sterilised bottles, and when he comes across induration draw a sample of milk, send it to the inspector, and if he gets a reply as "positive" report the animal at once, if "negative" reply then both the veterinary surgeon and his client can do as they like with the animal without risk of prosecution.

Tuberculin testing is a subject which has already been pretty well discussed. My opinion of the tuberculin test is that it is perfectly reliable if carried out in a systematic manner, and if reliable tuberculin is used. But I am afraid it is not as reliable when applied under the Order of 1913, and as the Order at present stands. If the test was applied to clinically affected animals then I would have more faith in it, but when you come to apply the test to tuberculous animals with emaciation then I am of opinion that 25 per cent. will give no reaction.

I note Mr. Douglas says the reaction is often got early, this I find by experience to be true in some cases, but in others neither the subcutaneous or ophthalmic test gives any reaction at all. Then when we come to udder cases, the test is not so reliable as one would wish because in indurated udder cases we very often have a fluctuating temperature due to the animal being in bad health, the temperature at one time may be 102°, in a few hours there may be a rise to say 103° or 104°, and this may be due to other causes than tuberculin.

Although I pass this remark about the tuberculin test under the Order I am open to conviction, and don't mean to say the inspector is misled by its action. He has other methods which, taken in conjunction with the tuberculin test, will guide him; he has the clinical examination of the animal, the sputum, the excreta, and the milk.

In sampling the milk of a tuberculous udder I am of opinion that the samples often vary, due to the condition of the tubercles in the udder. I think it even possible to get a "negative" sample from a tuberculous udder at one time, and at another time get a sample teeming with bacilli, due to the breaking up of some of the nodules, so I think that in suspicious cases the animal should be kept under supervision for some time before giving a decided opinion, unless we get a "positive" result on first sample.

The remaining part of the paper is taken up with the

examination of cattle in markets; the cost of the Order is also touched upon and Mr. Douglas gives his experience on the working of the Order in his district. These points can be better spoken of and discussed by inspectors under the Order, and we private practitioners will be delighted to hear their opinions and profit by them. I hope others will give us the benefit of their experiences.

This terminated the reading of the paper and a very interesting discussion followed on the various points brought out by the essayist, in which Messrs. McGeoch, Jas. F. Taylor, H. Begg, and the Chairman took part.

A cordial vote of thanks to Mr. John Taylor, and also to Mr. Thos. A. Douglas, for presiding, brought the meeting to a close.

J. F. MACINTYRE, Hon. Sec.

ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION. [NATIONAL V.M.A.—SOUTHERN BRANCH].

The annual general meeting was held at the Great Western Hotel, Reading, on Friday, January 30th. At the meeting the President (Mr. J. C. Coleman, Swindon) took the chair, others attending being Messrs. W. A. Hancock and W. T. D. Broad (Vice-presidents), Percy J. Simpson (hon. auditor), G. P. Male (hon. sec. and treasurer), Prof. Brayley Reynolds, and Messrs. J. R. Baxter, H. S. Dunn, J. W. Hopkin, J. H. Parker, S. H. Slocock, and R. J. Verney; and Mr. Theo. Toope (visitor).

Apologies for Absence. The HON. SEC. announced a large number of letters and telegrams of apology from members.

Title. Mr. SLOCOCK gave notice that at the next meeting he would bring forward a resolution to delete the word "medical" from the title of the Association, so that in future it should be known as "The Royal Counties Veterinary Association."

THE INTERNATIONAL CONGRESS.

The HON. SEC. announced a letter from Mr. F. W. Garnett, in which that gentleman gave a list of those gentlemen who had not yet paid the subscription which they had promised—they were only few, and expressed the hope that others would subscribe as money was badly needed.

THE LATE MR. W. HUNTING.

The HON. SEC. read a letter from Mr. G. E. King, of Abingdon, who could not attend the meeting, expressing the hope that this Association would vote a donation to the Hunting Memorial Fund. Mr. King said he believed it was contemplated to establish a lectureship modelled on the lines of one of the lectures given annually by someone who had done special work to further professional knowledge. Their late friend, he added, was so untiring in his efforts, and so devoted to the interests of the profession that he considered they should do something to perpetuate his name.

The PRESIDENT quite agreed that the Association should subscribe to so worthy an object.

Mr. SLOCOCK said that members of this Society saw a great deal of Mr. Hunting, as did the Central, and they always benefitted by his presence at their meetings. He moved that the sum of five guineas be subscribed by the Association towards the Hunting Memorial Fund.

Mr. VERNEY seconded the resolution, which was carried unanimously, and Mr. Male added that he knew many members were subscribing individually.

THE DEATH OF MR. WM. WILSON.

The HON. SEC. said he had to record with very great regret the death of another very old member of their Association, Mr. William Wilson, of Berkhamsted. He did not know of it until he saw the announcement in *The Record*, and consequently he was unfortunately unable to arrange for the Association to be represented at the funeral, or to send a wreath. He had, however, written to the members of the family and received a reply, which he read. Mr. Wilson was much esteemed and respected by them all, and was one of the oldest members of the Association, of which he was President in 1891.

On the initiative of the President, those present stood to pass a vote of sympathy with the family of the deceased gentleman.

The Accounts. The HON. AUDITOR (Mr. P. J. Simpson) presented and commented on the balance sheet for the year ended Dec. 31, 1913, observing that the accounts had been so nicely kept that he had found no trouble in checking them. The figures showed a balance at the bank, of £57 14s., as compared with £53 2s. 8d. brought forward. He suggested that Mr. Toope should be asked to get definite information from the National Association as to whether members of more than one Society should be paid for by each of the societies of which they were members, or only by one of their affiliated Associations; and Mr. Toope said he would see that the matter was mentioned in due course.

Representations on the Council. Messrs. J. C. Coleman, P. J. Simpson, and W. A. Hancock, with the Hon. Secretary, were unanimously elected representatives of the Association to the Council of the National Veterinary Association.

Next meeting. It was resolved, on the proposition of Mr. Parker, seconded by Mr. Male, that the next meeting of this Association be held in April at Faringdon.

Mr. SIMPSON read the following report of Mr. Male, who had acted as delegate to the Sanitary Institute Congress at Exeter. [Mr. Male was suffering from severe sore throat.]

ROYAL SANITARY INSTITUTE CONGRESS— REPORT BY MR. G. P. MALE.

Mr. President and Gentlemen,—As you will remember, our President, Mr. Coleman, was elected to act as your representative at the Exeter Congress, but at the last minute he was prevented from attending, and as I was representing the National Veterinary Association, he wired asking me to take his place as your delegate also. This I was pleased to do, and now beg to present my report, although I feel sure in doing so that you will all regret with me that he is not addressing you to-day instead of myself.

The Congress was well attended; in fact, the hotel accommodation was taxed to its utmost to provide room for all the visitors. With another of our noble profession I arrived rather late, but was lucky enough to find where to lay my head for the night. I made a special note for future Congresses to always book a room in advance.

Next morning at breakfast I found myself in the midst of a number of medical officers of health, who were freely discussing the Congress, and all decided to attend the Veterinary Section, which, they said, was by far the most interesting part of the Congress meeting that day—i.e. July 9th. This proved to be the case. The room was crowded, the discussions were brisk and well sustained, and participated in by medical men, laymen and sanitary inspectors, besides veterinary surgeons.

Members of the profession from the West of England were in force, but I regret to say there were but few from other parts, possibly owing to the distance that had to be travelled to the meetings.

Professor Penberthy presided, and is to be congratulated on the able and tactful manner in which he conducted the business. His address was a survey of the questions especially affecting veterinary surgeons and public health, and coming from one who is Chairman of the Contagious Diseases Committee of the Central Chamber of Agriculture, and who has always taken the greatest possible interest in these questions as affecting agriculture. It appeared in *The Veterinary Record* and in the *Journal of the Royal Sanitary Institute*, and should be read by every member of our profession.

He intimated his belief that the Tuberculosis Order was only the initial step in the crusade against tuberculosis in cattle, and described the Order as being a very moderate one, agreeing with the principle of it, except as to the amount of compensation given to the owner of the diseased animals and the source from which this compensation comes. He thought it should be a matter of national health and paid out of the Exchequer. He believed that in five years further legislation would be forthcoming, and suggested that there should be further investigation of tuberculosis from animals to man, and especially the part that may possibly be played by tubercle bacilli of bovine origin, in conferring some immunity to the human species.

Mr. Wm. Ascott's paper on the Milk and Dairies Bill was well received. He pointed out the pressing need there was for such a measure, graphically described the condition of some of the cow byres in his district, and urged that the cows themselves should be thoroughly and frequently inspected, on the principle that "prevention is better than cure." He welcomed the Milk Bill, but thought it should not be permissive as far as the rural district councils were concerned but compulsory, otherwise it would be a dead letter.

Those contributing to the discussion were Dr. Garnett, Dr. Fremantle, J. A. Dixon, M.R.C.V.S., J. W. McIntosh, M.R.C.V.S., J. Dunstan, M.R.C.V.S., A. H. Archer, M.R.C.V.S., and myself.

If the medical officers of health that spoke were representative of the others, there should not be much antagonism in the working of the Order. They freely acknowledged that the veterinary surgeon was an expert, and that he should work in collaboration with the medical officer.

Mr. Dixon did not agree with giving compensation to the farmers; he thought they had been "molly-coddled" too long.

One speaker thought there might be some overlapping between the Tuberculosis Order and the Milk Bill, as under the Milk Bill there was no provision for slaughter, and compensation that had to be dealt with by another authority.

Mr. W. P. Stableforth, F.R.C.V.S., presented a very practical and carefully thought paper on "Bovine Tuberculosis: its Diagnosis," and it was unfortunate there was not more time to discuss it thoroughly—this remark also applies to the other papers.

Mr. Stableforth held the view that the examination of milk was a matter for the expert bacteriologist, and described the difficulties in diagnosing tubercle bacilli in some samples of milk. Also that veterinary officers should be full-time men. His remarks, which somewhat reflected on the capability of the veterinary surgeon to do bacteriological work, met with some opposition from the President and other speakers. All agreed as to the value of the tuberculin test. Those taking part in the discussion were Dr. Gamble, Dr. Kerr, and Messrs. Bond, Dixon, Glover, and your delegate.

Mr. A. H. Archer, M.R.C.V.S., who prepared a paper on the "Transmission of Diseases by Animals to Man," was unfortunate in that his paper was not printed owing to a clerical error, so the discussion was somewhat limited. He emphasised the necessity of guarding against infection from animal sources, especially from cats, dogs and birds.

PRIVATE SLAUGHTER-HOUSES, PUBLIC ABATTOIRS, AND FREIBANKS.

The last paper, which was ably introduced by Dr. H. Jones, in the absence of Dr. Peck, was in support of a resolution, which was afterwards unanimously carried, to abolish private slaughter-houses.

It was pointed out by several that there were great difficulties in the way, especially in rural areas, but a member from Scotland spoke of the success of the public clearing-houses in some parts of that country, and thought a similar system could be adopted here.

The serious part of the business over, the rest of the day was spent in receiving hospitality, first from the Western Counties Veterinary Medical Association, who entertained your delegate with others most royally, and later the Mayor and Mayoress gave a conversation, which was a brilliant function and largely attended.

A conference of medical officers of health was held the next day, which your delegate attended and held a watching brief in the interest of the veterinary profession. Four papers were read and discussed very briefly, but with the exception of one of them they did not directly concern us.

This was my first visit to a Sanitary Institute Congress, and I was greatly impressed by the absolute necessity of delegates being sent to these gatherings. If we as a profession are to hold our place in the race for recognition, we must use every legitimate endeavour to advance our claims, and if we wish to be considered a scientific body and to have our opinions sought and respected by other branches of science, then we must take a share in these discussions and prove our worth.

In conclusion, I should like to thank you and the National Veterinary Association for allowing me the privilege of representing you.

The PRESIDENT remarked that he was very glad to see that Mr. Male had discovered that medical officers of health did not oppose veterinarians, which was not his (Mr. Coleman's) experience. The overlapping of duties under the Dairies and Cowsheds and the Tuberculosis Orders was a very serious matter, and one which required grappling with with some strength. In his own borough (Swindon) after many years the medical officer of health had decided that cows should be inspected in company with him (Mr. Coleman); and the Council last February ruled that that should be done; but the medical officer and the town clerk put their heads together and said that as the Tuberculosis Order was coming into force in May it should be deferred; and nothing had yet been done. He had great pleasure in moving a vote of thanks to Mr. Male for his very elaborate yet concise report. (Hear, hear.)

Mr. SIMPSON seconded the vote of thanks with much pleasure. As to veterinary surgeons attending those Congresses he—having been to one or two of them—could back up Mr. Male's remark. He had found the veterinary surgeon thoroughly well received there, and his opinion thoroughly well respected—in fact he was better appreciated by medical officers of health than by veterinary surgeons. It would well repay any country practitioner to spare two or three days and the guinea subscription to go to the Congresses of the Sanitary Institute or the Royal Institute of Public Health, as he would combine pleasure with business. (Hear, hear.)

This was cordially passed, and acknowledged.

CASES OF INTEREST.

Mr. MALE said he was allowed to show a rather interesting case through the courtesy of Mr. Owen, of Thame, a former member of their Association, who sent him a horse, as he said "either to kill or cure." Mr. Owen would have come himself that day but that he was absolutely prevented from doing so by some family matters. The horse, which won a second prize as a two-year-old at the Oxfordshire Agricultural Show, was now five years old. Mr. Owen wrote that he found a remarkable enlargement of the maxillary bone, and had tried all sorts of things without success; he fancied the injury might have been caused by a kick while the animal was out at grass. Of course he (Mr. Male) would like to cure it, but he feared the only "cure" would be a bullet.

[The horse was afterwards brought out from the Great Western Hotel stables, and examined with much interest by the members].

Mr. HOPKIN brought the same curious calculus from a horse's cheek, where it had been for four and a half years, which he showed at the November meeting, and had since had sawn in two longitudinally. He thought it was a salivary calculus, though it differed a good deal from others he had seen.

SUGGESTED VETERINARY INSPECTORS' SECTION.

Mr. TOOPE said he had been granted the privilege of making a few remarks on a scheme which he had suggested in various places, and which he thought might bring about good feeling between those who were not veterinary inspectors and those who were. He suggested that this Association should form a veterinary inspectors' section, which should meet an hour previous to the general quarterly meetings of the Society and discuss any cases of general interest to themselves. All members of the profession should be invited, and those who attended more than once at such gatherings would, he thought, soon become members of the Society, thereby increasing its strength, as well as assisting materially in the elucidation of the difficult problems of the day, and of the future, which would be still more difficult. That plan had been in operation in the South Eastern Counties now for some two years, and at the last meeting a fortnight ago no less than 21 turned up from Sussex, Surrey, and Kent, and had a very interesting discussion on some aspects of the Tuberculosis Order. In addition to that he (Mr. Toope) arranged for a microscopical display. By that means they had in Kent very largely increased their fees, and had placed themselves in quite a different position to that which they held formerly with regard to the medical officer of health, to the Contagious Diseases of Animals Committees, who now referred to them for advice instead of giving them an order to proceed at their price (Hear, hear). A union of that sort was bound to cement friendship, and also to benefit every member of the profession, inasmuch as it would increase his social position and his influence with the authorities by whom he might be employed. All that was necessary was to invite the veterinary inspectors in the different counties to send a deputation representing each county or authority at their meetings; and in that way they could get a general consensus of thought. Other counties were taking such action. In Aberdeen, where the pay was simply shocking, it is now something like 30 per cent. more than it was before. He, as a borough inspector, undertook the whole of the duties under the Order, microscopical examinations, etc., save and except the biological test, which he had arranged to have done in London. The medical officer had offered to do the work at a reduced rate, but he (Mr. Toope) was continuing to do the work; and he said he should certainly decline to take the samples for the medical officer of health for nothing.

The PRESIDENT said the idea seemed to him a good one. Anything in the way of bringing them together to discuss debatable points must always be an advantage. (Hear, hear).

Mr. MALE said they should have time to think about the matter. Perhaps if Mr. Toope would kindly come down to their next meeting they could discuss it fully. As far as Berkshire was concerned, they had practically done it on a small scale, their advice on the Order had been asked and their fees had been granted, and he thought the inspectors in the other counties had done the same thing.

Mr. TOOPE said they had been so far fortunate, but there were other matters for consideration which would arise.

Mr. SLOCOCK thought the suggestion an excellent one. In Middlesex, where they were quite content, they had not perhaps joined the inspectors in the same spirit that other counties had. He agreed with Mr. Male that the matter wanted a great deal of ventilation, and he proposed that it be placed on the agenda for the next meeting.

Mr. HANCOCK seconded the resolution, which was carried unanimously, and Mr. Toope promised to do his best to attend the meeting.

New Member. Mr. W. G. GREEN, of Rosenheim, Boscombe Park, Bournemouth, was proposed by the President, seconded by Mr. Broad, for election as a member of the Association at the next meeting.

PRESIDENTIAL ADDRESS.

J. C. COLEMAN, F.R.C.V.S., Swindon.

I feel that you have done me a very great honour in electing me your President for the ensuing year. The Association has numbered among its members and past presidents many of the leading lights of our profession, and I feel very deeply the grave responsibility that devolves upon me to maintain the position which this, of the oldest of veterinary societies, has attained. Further, the year 1914 I feel sure will be one of the most important in the annals of our profession and will stand out as "red-letter" year for all time.

I am more anxious that during my year of office members of our profession, especially those of the Royal Counties Veterinary Association, shall truly realise their position and duty both to the public and themselves, throwing aside lethargy, each member setting to work in earnest to educate their respective authorities to the absolute necessity of our inclusion in the official administration of all Acts or Orders relating to public health where the lower animals are concerned. More particularly I refer to the proper inspection of meat and of all cows supplying milk to the public.

It has been suggested that we should have a representative at the Local Government Board. I shall welcome a discussion upon this point at a future date, and, if your opinions be in the affirmative, that steps be taken to bring the suggestion before the proper authority.

I would like our profession to show its gratitude to those who sacrifice their whole lives in scientific research for the purpose of discovering the cause, prevention or cure of disease, by taking an intelligent interest in these matters and making themselves conversant with their discoveries.

Quite recently I saw it stated that a medical practitioner had fed two or three cats upon, and had himself consumed, a quantity of milk from a known tuberculous cow, and none of them had contracted the disease, and upon this very meagre evidence he dared to refute the decision of those savants who had made exhaustive investigations and had proved beyond doubt that the disease is capable of transmission and is also contagious.

To obtain legislation upon any subject it is first necessary to arouse public interest, and to attain this end they must be educated upon the matter at issue. The expression of an adverse opinion, as above cited, and which had probably been arrived at too hastily by one who *should* know something of the subject, tends to considerably delay progress, as the lay public are ever ready to grasp at the smallest particle of what appears to them to be reliable evidence which flatly contradicts other evidence which has already caused them alarm.

The age of "bluff," and "the only object in life to obtain fees," is largely passed away, and in the near future only those men who have a sound and up-to-date scientific education and an innate love of their profession will succeed.

"Our profession needs no bulwarks
No towers along its steepes,
Our march is onward 'midst disease,
And 'science' still our motto keeps."

During the ensuing session of Parliament we hope to see the passing of the Veterinary Surgeons Amendment Act, otherwise bankruptcy seems to stare us in the face.

In August next the Tenth International Veterinary Congress is to be held in London, and it is the duty of every member of the Royal College of Veterinary Surgeons to make an individual effort, however small, to ensure the Congress being a huge success. I am an advocate that every one should do what little they can and not leave the whole to a few energetic men, who are ever ready to come to the rescue when the honour or advancement of our profession is at issue.

Sir Stewart Stockman informs me that the total subscriptions have not yet reached the minimum sum estimated to be required. Any gentlemen who have not already subscribed, or who wish to increase their amounts, may be assured that however small they will be welcomed. I have no doubt that our worthy Secretary and Treasurer will be pleased to receive and forward the same to Mr. Garnett and save you the trouble of so doing.

I trust that some of our younger members will give us the benefit of their more recent tuition, by coming forward with papers or practical demonstrations of recent methods of diagnosis, treatment, or prevention of disease. Also, that our meetings will be well attended and discussions sustained.

My own deep regret to-day is the absence from our gathering of one who was beloved and admired by every member of our profession who knew him, and a host of members of other professions, and whose memory it is proposed to perpetuate. We who knew him cannot do better than by doing our very best to emulate his noble example. Needless to say, I refer to William Hunting.

I beg to thank you all most sincerely for having done me the honour of electing me your President for 1913-14, and I only trust that with your support I shall leave this chair, your confidence increased and my profession losing nothing of its professional status.

Mr. MALE and Mr. Hopkin were thanked for their specimens, on the call of the President, seconded by Prof. Reynolds.

Mr. HANCOCK moved a very hearty vote of thanks to the President for his Address, in which he had touched on topics of great interest to the profession.

Mr. SLOCOCK seconded the resolution, and the same was carried by acclamation.

THE DINNER.

The PRESIDENT filled the chair at the annual dinner which followed the meeting, and which was attended by the gentlemen named above, and by the following visitors and members who had been unable to take part in the business proceedings:—Visitors: Ald. J. W. Martin, Deputy-Mayor, and Councillors W. J. D. Vennor and John Eighteen, Reading; Ald. W. W. Dickson, Swindon; Mr. H. W. Boileau, Master of the South Berks Foxhounds; Dr. Stenhouse Williams, Professor of Bacteriology at Reading University College; Mr. A. G. Hutchinson, and Mr. Hugh McCormack. Members: Capt. O'Rorke, Mr. R. C. Tennant, and Mr. Hunt.

The toast of "The King" having been loyally honoured on the call of the President,

Prof. REYNOLDS gave "The Imperial Forces." The British Navy, he said, was undoubtedly the best Navy in the world, and it was their duty to see that it always remained so. Undoubtedly large sums were being spent annually on armaments, but if they looked on it as a matter of insurance, as they were all quite willing to do, and in view of the fact that other nations were nowadays, perhaps, shifting Britannia's trident to their own, they would not grudge the cost. Of one thing they were sure, that if it ever came to the test it would be found that those other Powers had not found the secret of producing the men who worked the British Navy. (Applause.) With regard to the Army, it was insignificant in comparison with the Armies of other European countries as regarded numbers, and that fact made it the more necessary that our Navy should be fully kept up. He had seen active service on land, and could say he believed our Army to be perhaps the best in the world for its number. Speaking as to veterinary surgeons, they should be proud of their members, who formed a corps of some considerable importance, and was one of the smartest Corps in the Army. (Hear, hear.) As to the Territorials, it was a pity that they had not got their full number.—(Ald. Martin: We are above our numbers in Berkshire.)—He was very glad to hear that, and if the same could not be said of other counties, conscription would have to be resorted to. (Hear, hear.)

Capt. O'RORKE, Army Remount Department, Arborfield, responded in a few words. Prof. Reynolds had, he said, proposed the toast so excellently, and it had been received so cordially, that he need say little. As to both Navy and Army—although the latter was so small numerically—he was convinced that in both we had the quality, and when they got to actual service, British pluck went a long way. In the past our Navy and our Army had kept this country to the front, and he believed that they would always do so. (Applause.)

Ald. MARTIN submitted the toast of "The Veterinary Profession." They lived, he remarked, in very competitive days, and had a great many difficulties to cope with. Their profession, above all others, at the present moment had to bear in mind motor cars and other matters which seemed to dispense with the use of the "gee-gee." At the same time the valuable services of the veterinary profession would always be required in connection with horses and other animals. He well recalled the late Mr. Wm. Flanagan, of Reading, as a most accomplished man, of whom they were very proud, and also his partner, the late Mr. Wheatley. He (the speaker) had attended several most pleasant social gatherings of the profession, twice when he was Mayor of Reading, and now as Deputy-Mayor, and he had never come across nicer men, socially and intellectually. Even laymen knew that their profession was indeed more onerous than even the medical profession itself. They were bound to go out at all times of the day and night, and he did not think they were too well paid. In

these days, unless the members combined, it was impossible to keep any profession up to the proper standard. (Hear, hear.)

Mr. SLOCOCK responded. Although small in numbers, he said, they all regarded their profession as an honourable one, and it was especially pleasing to have that toast proposed by such a prominent member of the legal profession as the Deputy-Mayor of Reading. He might be an optimist, but he had not yet accepted the idea that the veterinary profession was going downhill. He believed their total earnings exceeded those in any earlier year, their numbers were likely to increase, and their status was higher than at any time owing to the individual action of the members locally. The profession was well guarded by a Council, of which he (Mr. Slocock) had the honour of being a member. They had the one-portal system, of which they were so proud and so jealous that on no ground whatever would they give it up, however much they might sacrifice. The Council was poorer than it had ever been—was verging on bankruptcy—their sole source of income being the fees from students and the small fee for the Fellowship Degree. It was the duty of the Council to see that the country was provided with a sufficiency of well-trained veterinary surgeons. They had made the proud boast that their students before entering should pass a matriculation examination equal to that of any of the learned professions. The time seemed now arriving when they could no longer make that their proud boast. The Medical Council had raised its status, and could the Veterinary Council to-day raise their standard when they had so much smaller a number of students? It seemed to him that the only way was for them to combine to get the Veterinary Surgeons Amendment Bill passed—and it was bound to come. The profession in no way blocked that harmless Bill, only the fragments of which remained. They did endeavour to get a Bill passed which would have given them better powers for the protection of their status and the abolition of quackery, but that brought about so much opposition that they were obliged to be content with a measure just for their own management. They had now just framed a bye-law that would exempt those who had taken degrees in arts and sciences from having to submit to the first year's examination, of course with certain provisions as to anatomy, etc. Then there had been a variety of Charters, and they found it necessary now to apply for another, which he thought would not meet with any opposition if any in the House would find time to push it through, but they would have to approach the Members of Parliament in their divisions and see what help they could get. The new supplemental Charter was making certain provisions (to which the speaker referred). They wanted to see men specialise, and it was recognised that for a man to specialise he need not have been a practitioner for five years—a man could become an ornament to his profession with two years of specialised work. Then it was thought there should be a diploma in State Veterinary Medicine for the protection of mankind—such things as the Milk Bill and the Tuberculosis Order and the number of appointments made for veterinary surgeons under Municipal bodies, for which it was felt that there should be a line of study to particularly qualify those men for their work. They wished to draw out some syllabus, perhaps in connection with the Universities, for degrees in State Veterinary Medicine. (Applause.)

Mr. TOOPÉ gave "Success to the Royal Counties Veterinary Medical Association, its President, and Officers." That, he said, was his first visit to the Society, but he hoped it would not be his last. They had the right man in the right place as their President, and his genial hospitality would, he was sure, add a large number of members to their ranks. (Hear, hear.) In regard to their Secretary and Treasurer, he was a

hardworking man not only in that capacity but also on the Committee of the National Association. (Applause.)

The PRESIDENT said theirs was a really up-to-date Society; and he hoped that during the year members would get so used to coming to the meetings that at the next annual dinner they might have many more present. Success in all those things entirely depended on the attendance, and the comparing of notes. The day when men having got their diplomas thought about nothing but making up a little physic to get half-crowns was gone. He sincerely hoped that at the end of the year the Association would not have lost anything through having such a very indifferent president as himself.

Mr. MALE briefly returned his thanks.

Mr. HANCOCK proposed "The Mayors and Corporations of Swindon and Reading," saying they regarded as a matter of very great importance such meetings with members of corporations and members of their profession. Particularly in recent years, when diseases communicable from animals to men, and *vice versa*, were so much studied, such meetings were a great deal more important than they had been in the past. (Hear, hear.)

Ald. W. W. DICKSON (Swindon Corporation) said Reading was a County Borough, and Swindon was trying to become one. They were very well served on their Corporation, so far as the veterinary profession was concerned, by Mr. Coleman, whom he had found during the past 17 years a very good friend and a good practitioner. It was very difficult to carry out the Acts with regard to meat and milk; and he was sure Mr. Venner and Mr. Eighteen could tell them more than he knew about those matters. Medical officers often did not collaborate with veterinary surgeons, arrogating to themselves powers because they were members of the medical profession. The public should understand that although the medical officer was pre-eminent the veterinary officer should be pre-eminent in looking after their milk and food, and so on. (Hear, hear.) He had had a most enjoyable evening and he felt greatly indebted to their President for inviting him there.

Ald. MARTIN also replied. In Reading, he said, they had a most able and competent veterinary surgeon. Mr. Male had dealt with most difficult questions with painstaking care and skill, and great ability to the advantage of the Corporation and the inhabitants. (Hear, hear.)

Mr. VERNEY, in proposing "The Medical Profession," said he could not understand what he heard about any difference of opinion between them. He had always found medical officers of health most amenable men, and gave examples showing the cordial relations in which they worked.

Dr. STENHOUSE WILLIAMS began his response by saying that while no doubt there were medical officers of health and medical officers of health, there were also veterinary surgeons and veterinary surgeons. Before he came to Reading he was in charge of the Bacteriological Department in the University of Liverpool, and many of the old students were medical officers throughout the country, and they were a very fine lot if taken in the right way. There was, and should be, very close contact between the two professions. (Hear, hear.) The veterinarian was in a more difficult position than the doctor, because, except in the case of children, the latter could get some account of what had gone before his patient, whereas the veterinarian always had to face enormous difficulties in making his diagnoses. When he (the speaker) came to Reading, the Tuberculosis Order was just out, and he was asked to write something in the nature of a pamphlet on the subject for the benefit of the farmers. If they were going to produce any effect on a farmer they must tell him straight the effect of his loss; and so he asked how to get accurate

statistics of the number of deaths from tuberculosis among cows, and nobody knew. The Board of Agriculture referred him to the Local Government Board, and the Local Government Board referred him to the Board of Agriculture and then he referred to Mr. Male, and he did not know. If they were going to do any good by regulations, orders, or Acts of Parliament it was clear they must have the facts. Until they knew what animals were dying from any disease they could not call on the Government to take any specific measures. Perhaps they did not know what was well known to those at the Agricultural School at Reading, that there was at the present moment a very large body of the more intelligent farmers who would feel extremely glad to eradicate tuberculous cows from their herds. Some of them had formulated a scheme to start a farm to supply farmers with absolutely guaranteed non-tuberculous stock; and they reckoned that in order to put the thing on a preliminary basis and run it on absolutely clear lines, they wanted a capital expenditure of about £4,000. If they found it necessary to put out an appeal it would be of great service to them to feel that they had the support of this Association. (Applause).

Mr. TENNANT proposing "Fox-hunting," said it would be a bad day for the profession if the sport were given up. (Hear, hear).

Mr. BOILEAU, M.F.H., Master of South Berks for the last three years, said he had been very closely allied with veterinary surgeons for some time past, and had always accepted their verdict. He was very pleased to know Mr. Male. He had always ridden straight, and he (Mr. Boileau) was always glad to see him in the hunting field. (Applause).

"The Visitors" were toasted on the call of the President.

Mr. VENNER replied as a member of the Reading Corporation and Chairman, and also as a private trader. He had always held that inspectors of cows and of the food supply should be qualified veterinary men.

Mr. EIGHTEEN, Chairman of the Farm Committee, said he did not know of any Corporation who had done more than that of Reading to stamp out the terrible disease of consumption. Their veterinary surgeon had not condemned their animals wholesale, but he had tested them, and last year's report showed 64 of their cows out of 65 had passed the test. (Applause.)

Mr. MCCORMACK also replied, mentioning that the President, Mr. Tennant, Mr. Hopkin, and he were students together at College.

The harmony was contributed to by Messrs. P. J. Simpson, Hunt, Hopkin, and Hancock, with Mr. E. E. Langston as humorist.

G. P. MALE, Hon. Sec.

SOUTH EASTERN VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

VETERINARY INSPECTORS' SECTION.

A meeting was held immediately preceding the annual meeting at Tunbridge Wells on January 15th. The retiring President (Mr. James Crowhurst) presided, and there were also present Mr. G. H. Livesey, President Southern Counties V.M.A., Messrs. E. Lyne Dixon, P. Gregory, Elmer Ebbetts, C. Crowhurst, J. H. Ripley, A. C. Burton, T. A. Huband, J. B. Dier, W. Caudwell, H. P. Hogben, T. F. Hogben, P. J. Austin, D. Reid Chalmers, T. Hibbard, J. Basil Buxton, E. W. Morris, G. Fordham, W. R. Emery, W. W. Gulleford, and Theo. C. Toope, hon. secretary.

The PRESIDENT extended a cordial welcome to all present, and said he understood there were some visitors from Sussex and also from the Southern Society with them.

Correspondence. The Hon. Sec. said that at the last Veterinary Inspectors' meeting the question arose as to what were the duties of the inspector on finding a case of tuberculosis in markets. He was instructed to write to the Board of Agriculture and also to the County Council with regard to it. He wrote to the County Council and he had received a reply which in no way answered the question. He wrote again on the same day he received the first letter, as follows:—

34 High Street, Dover.

Dear Sir,

Sept. 23, 1913.

Many thanks for letter. I fear I did not make my point quite clear, I will assume a case:—

A., a farmer at a distance, exposes a cow suspected of tuberculosis in open market. B., the veterinary inspector, sees it, and orders it out. A. and B. meet and A. agrees to have it destroyed at once without claiming any compensation. B. finds his suspicions confirmed on post-mortem. The query is—under above circumstances should B. examine all other bovines on A's premises, or, if outside his district, cause such to be done by C., i.e., the veterinary inspector for that district.—Yours, etc.,

THEO. C. TOOPE, Hon. Sec.

To that letter he received the following letter:—

Sessions House, Maidstone.

Dear Sir,

Sept. 24, 1913.

I am in receipt of your further letter of 23rd inst. If the animal is not taken back from the market to the premises from which it was brought, but examined by the veterinary inspector and destroyed by the owner at some other premises, there is no authority for *any veterinary inspector* to extend the examination to any bovine animals upon the premises from which such animal was taken to the market.—Yours faithfully,

(Signed) W. B. PROSSER, Clerk to Kent C.C.

Mr. CAUDWELL said he had looked the matter up in the Board of Agriculture regulations, and under article 14 of the Tuberculosis Order they were referred to Section 44 of the general Act, and it answered the above questions for them, that was having, if exceeding five or six days, full power to go and examine the other animals, if an animal was stopped in the market and slaughtered. If the district was in the jurisdiction of the inspector he had power to go and examine the other animals.

Mr. GREGORY said it seemed to him the old saying came true that there was never an Act of Parliament that they could not drive a coach and four through. He still thought, in spite of what Mr. Prosser said, that when an animal within a few hours of leaving the premises where there were many other cows, was brought into a market and exposed, and that animal was found to be tuberculous, they ought to be able to examine the cows on the premises from which the animal was sent, for in that way only could the perfect working of the Order be enforced.

Mr. EBBETTS said they could go and examine stock on the premises from which a tuberculous animal had been sent, but the questions were "Were they supposed to do it?" and "Ought they to do it?" That was what he would like cleared up.

Mr. GULLEFORD said anyone who had done it and had sent in his account had been paid. He did not know that it was professional to mention matters of £ s. d., but he had inspected stock on the premises during the past quarter, and he believed he did it the quarter before and his account was paid.

Mr. GREGORY gave an instance where an owner had an animal killed in the market and he (Mr. Gregory) went to the farm the next day and examined all the other stock.

The SECRETARY: This letter, then, I have received, is of no value whatever.

Mr. GREGORY: I think not.

The PRESIDENT said of course inspectors only had power in their own districts. They had no power to go into another inspector's district, and if they did they would be exceeding their orders altogether.

Mr. H. P. HOGBEN said he asked the Superintendent of Police of his district and he said he had received orders to follow up animals.

Mr. EMERY said he believed an inspector was entitled to follow an animal to its death.

Mr. GREGORY: Not when it is taken into another district.

Mr. EBBETTS, replying to Mr. H. P. Hogben, said the Act pointed out that when an animal was taken into another district they were to report the case to the police in the district to which the animal was taken.

The PRESIDENT said for the effectual working of the Order it should be where an animal was discovered to be affected with tuberculosis, or was strongly suspected, it should be followed up; but people were getting very learned in his district. He knew a dealer in cattle, who bought an animal knowing it was a suspected case of tuberculosis and took it to premises where there was no other stock. The animal was dealt with, but the inspector was not able to follow it up and make the Act effective by examining the animals it had been in contact with. In addition to that the man had another animal and he told him (Mr. Crowhurst) that as soon as this was dealt with he would bring another one to the same place to be dealt with in the same way. If they read between the lines they could see that some dairymen objected to the presence of the veterinary surgeon to inspect his stock, and to avoid it he got a dealer to take the animal to an isolated place and then give notice. It was a way of getting over the Order altogether. This case he had thought of bringing before the County Council for them to see what could be done. He thought it was a case in which the police should find out where the animals were brought from, so that the stock could be examined by the inspector. He did not think it advisable to pass a resolution at that meeting, because if the man gave notice to again do as he had intimated, he should write to Mr. Prosser and ask for instructions as to following up the animal.

Mr. GULLEFORD asked whether in the event of an animal being removed into another district it was their duty to give notice to the veterinary inspector in the neighbouring district.

Mr. GREGORY: Not the veterinary inspector, but to the police.

Mr. GULLEFORD said if a cow was to be moved into some other district he had to send a copy of his report under Article 11 to the police of that district, and would that not open their eyes.

The PRESIDENT said they could not compel a man to answer questions at all. They could put questions and the man could answer them if he liked. He did want it to go forth that a veterinary inspector only had power in his own district. He believed if a veterinary inspector were to go into another man's district to slaughter cows he would get into great trouble. It had been suggested that cases should be followed up by the inspector of the district in which the first case was discovered, which was evidently wrong.

Mr. H. P. HOGBEN said he received those instructions.

The PRESIDENT: It is against the Order.

The SECRETARY said he had invited members of the Southern Counties there that day, their President (G. H.

Livesey, Esq.) and several of them had come. He hoped they would be able to advise them and assist them if possible in the formation of an inspector's section of the Southern Counties. He thought they had only to see the zest with which the members of that Society worked to see that the suggestion he made at the Southern Counties meeting was invaluable. He trusted they would be able to help them by advice and by their experience in showing them what the effect of a combined meeting of veterinary inspectors, or a union of veterinary inspectors, in any county or in any division could do. His suggestion to them at Brighton was that they should form themselves into a section of the Southern Society. It was adopted and referred to their next meeting, but unfortunately that meeting in London was attended by very few. It was therefore suggested that he should bring it up again that day. He was pleased to see that several members of the Southern Counties had turned up in order to keep the subject warm. He presumed it would possibly be better to hold the matter over to the next meeting of the Southern Counties in March. The suggestion was that the Southern Counties should form an inspectors' section in the same way as the South Eastern Association had. He thought by coming there they could ask questions as to the working of the section, which would probably help them. He would go further and ask every Society in the Southern Branch of the National to follow their lines. The suggestion was that the veterinary inspector of each county or administrative body should hold a veterinary inspectors' meeting, and that delegates should be sent to those meetings of veterinary inspectors held in connection with the various societies if they could not attend in a body; and then through the Society, matters could be handed on to the National Veterinary Society. He believed the result would be that universal good would be derived from it. It was a process of decentralisation whereby every unit, each different section, that is the counties, etc. would be affiliated to the National and could make suggestions for the common benefit of all and through their societies they would be represented on the National. He was speaking for more or less inducing not only the Southern Society but other societies to adopt this principle. In various parts of the country the suggestion was being adopted. It was a plan that had worked well with them in the South Eastern Society, and he was sure it would work well with other societies if they only adopted it.

Mr. CAUDWELL said that at the meeting of veterinary inspectors of the Southern Counties held at the Holborn recently it was resolved to form a committee and he understood that all the veterinary inspectors in the adjoining counties had been invited to attend that meeting that day, but he was afraid at the present time there was a great luke warmness and apathy about that question with many, and that the only way they could make a move in it was by seeing the veterinary inspector personally and trying to induce them to join them. Personally, he would see some of the inspectors under the Surrey County Council, to see if they would join them. He did not know whether he could do more than that.

The PRESIDENT said as President of that Association he was honoured by being invited as a guest of the Southern Counties, and he extended a very hearty invitation to the members of that Association to come there that day, and he was sure they had great pleasure in receiving them. (App.)

Mr. GREGORY said as far as he was personally concerned he attended the big meeting at the Holborn, and afterwards he wrote to Mr. Spencer at Kettering saying that he would be very pleased to join the Association, and if he let him know the fees he would remit. He had not heard a word since.

The SECRETARY: Nothing tangible has been done since the fees were altered, and that was not to their advantage in Kent.

The following gentlemen brought bacteriological microscopes and specimens. Messrs. B. Buxton, E. W. Morris, E. L. Dixon, J. H. Ripley, C. Roberts, and the Secretary.

Amongst the exhibits were to be found:—*Bacillus bronchosepticus*; *Bacillus* of abortion and cultures of John's disease; Human, bovine, and avian Tubercle bacilli, from Mr. Buxton.

Sections of *Bowel*—John's disease; *Udder*—Tuberculosis; *Tongue*—Actinomycosis; *Lung*—Pleuro-pneumonia contagiosa; Melanotic Sarcoma; *Bacillus anthracis*, showing capsules and spores; Milk smears with tubercle bacilli, from Mr. Morris, Uckfield.

Bacillus of John's disease from bowel scraping, from Mr. Caudwell.

Bacillus tuberculosis—an extremely rich specimen of milk smear. Cocci from smear nasal discharge of cat. Lung section—tuberculosis, from Mr. Toope.

These exhibits were viewed with much interest by the majority present, and constituted quite an important feature of the meeting.

GENERAL MEETING.

Continued from page 497.

Correspondence between the President, Mr. James Crowhurst, and the Secretary of the International Congress was read, and in consequence of what was obviously a misunderstanding as to the purport, it was decided to postpone further consideration of the matter until the next meeting.

The question of giving a subscription to the William Hunting Memorial Fund was left over till the next meeting, when the financial statement would be presented and the Association would know what funds were in hand. A general expression of sorrow and regret accompanying this discussion.

Mr. SHIPLEY wrote regretting he could not get to the meeting, and asking for support for the Victoria Veterinary Benevolent Fund, which needed help.

Mr. TOOPE said anyone who was prepared to support the Fund could send subscriptions to him or to Mr. Shipley. Personally, he strongly advocated the Fund to their notice.

Mr. TOOPE read a letter from the Mayor of Margate, Mr. W. B. Reeve, who had hoped to attend the meeting that day with Mr. Dixon, regretting that he was unable to fulfil his promise owing to urgent local matters.

Mr. TOOPE said last year they all thought that the Southern Counties were numerically badly represented on the Council of the Royal College of Veterinary Surgeons, and their worthy President, Mr. James Crowhurst, became a candidate, and with a little more assistance would undoubtedly have secured a seat on the Council. He (Mr. Toope) thought they ought to unite with the Southern and Western Counties in an attempt to get another member on the Council. There were only two representing all the Southern and Western counties on the Council at the present time, Mr. Burt, of Brighton, and Mr. Dunstan, from Cornwall. It was not fair that the Southern and Western Counties should be only represented by two gentlemen. He had not a word to say against other gentlemen proposed, but he wanted to see the representation more evenly distributed over the country. As matters are it was a very one-sided representation.

The PRESIDENT moved that Mr. James Crowhurst be adopted as a candidate for their support at the next election.

Mr. T. F. HOGBEN seconded, and the motion was carried unanimously.

Mr. G. LIVESEY gave his cordial support to the suggestion on behalf of the Southern Counties Veterinary Society.

Mr. CROWHURST, in agreeing to stand as a candidate, said with him that was no personal matter. He was only anxious to benefit the profession. He was a keen worker, and he had worked earnestly and zealously in the interests of the profession as a member of their Association.

THE ANNUAL DINNER.

This was held at the hotel in the evening. The President, Mr. E. L. Dixon, in the chair, supported by Major Skey, Margate; G. H. Livesey, Esq., M.R.C.V.S., President of the Southern Counties Association; the Ex-President, James Crowhurst, Esq., Mrs. Dixon, Mrs. Stretfield, Mrs. Toope, and other ladies to the number of thirteen. Mr. T. F. Hogben occupied the vice-chair, the gathering in all numbering thirty-eight.

It was unfortunate the Mayor of Margate, J. Booth Reeve, Esq., J.P., could not be present as he had fully intended, a telegram arriving from him during the function.

An excellent musical programme was arranged which interspersed with speech and anecdote gave rise to a pleasant evening. The Misses Hogben (Ash), Miss Mabel Adams (Tunbridge Wells), Mr. Septimus Dixon, M.R.C.V.S. (the President's brother), Mr. Percy Gregory, Mr. D. R. Chalmers, and others, contributing largely to the pleasures of the evening.

THEO. C. TOOPE, M.R.C.V.S., Hon. Sec.

CENTRAL VETERINARY ASSOCIATION OF IRELAND.

[NATIONAL V.M.A. IRISH BRANCH.]

A meeting was held at the Gresham Hotel, Dublin, on the 5th February. The following members were present: Mr. B. P. J. Mahony, President; Messrs. F. A. Heney, A. Watson, J. McKenny, P. J. Howard, J. F. Healy, J. W. Nolans, and E. C. Winter, hon. sec.

The list of members in arrear was gone through, and the Secretary was given a list of names with an instruction to strike them off the roll for non-payment of subscriptions.

ELECTION OF OFFICERS.

President.—Mr. B. P. J. Mahony, Maryboro'.

Hon. Secretary.—Mr. E. C. Winter, Limerick.

Treasurer.—Mr. J. F. Healy, Middleton.

Council.—Messrs. McKenny, Heney, Howard, Holland, Nolans, Moffett, Patrick, and Cleary.

The accounts for 1914 were considered and audited, and showed a balance of £24 odd in favour of the Association.

The Hunting Memorial Fund was then discussed, and it was decided to send £3 3s. as a subscription to this Fund, and the Secretary was directed to intimate to the Committee in charge of the Fund that the Association was of opinion that the best means of perpetuating the memory of the late Mr. Hunting would be to invest the major part of the money in some fund, and devote the annual proceeds to benevolent or scholastic purposes, and to designate it the "Hunting Memorial Fund."

The fact that no Irish practitioners have been recognised as fitted to take a leading part in the proceedings of the International Veterinary Congress (to be held in London this year) was strongly and adversely commented on by the members present.

The following resolution was proposed by Mr. Watson, seconded by Mr. McKenny, and passed unanimously:—

1. "That this Association is of opinion that the practitioners of Ireland should have direct representation on the Council of the R.C.V.S., and it is our intention to nominate a member for the next election, and we look to the Council and the other Associations to support our nominee."

2. It was proposed, seconded, and carried "That Mr. P. J. Howard, of Ennis, be nominated to stand for election to the Council of the R.C.V.S., by this Association."

The SECRETARY was directed to take the necessary steps to bring these resolutions under the notice of the Council of the R.C.V.S. and the profession generally.

"NOTES ON CLINICAL WORK."

By J. W. NOLANS, M.R.C.V.S., BIRR.

Mr. President and Gentlemen,—At our last meeting, in Ballinasloe, I was asked to contribute a subject for discussion at this meeting, and the consensus of opinion was in favour of some notes on cases in general practice. I will now try to bring before your notice a few cases I have met with that were interesting to me, but which I have no doubt some of our older members may have seen before.

Case 1. A brood mare, half bred, about nine years old, having had four foals and now in foal again. I got a message on the 12th April to come and see her. She was showing slight signs of colic. On arrival at the farm I found the mare rather uneasy, lying down and getting up alternately. The pulse about 46 and temperature normal. Gave hypo. morphia sulph. After a little she became quite comfortable, and took some bran mash. I visited again next morning, and was told she had not passed any faeces. Gave an enema when she voided a quantity. For the next week she took slight pains about every twenty-four hours, and I left some colic drinks to be given, which always gave her relief, and she showed complete recovery, and put on condition and looked well.

She was due to foal about the middle of June, and, early in July, I met the owner who told me the mare had not yet foaled, and about the end of July I met him again when he said she was not in foal, and he had sent her to the horse. About the middle of August I saw the owner again and he told me she was home, having passed all her trials. I heard no more until the 20th September, when the owner sent for me to come and see the mare again. She was getting very thin. I attended and found her very much emaciated and an enormously distended abdomen, particularly the lower portion. The day following my visit I got a message to say she was dead. Urgent business prevented me making a post-mortem for two days, which I then carried out.

On opening the abdomen, I found it almost full of fluid, the liver quite yellow and friable, and, just posterior to the diaphragm, a fully developed fetus completely enveloped in all the membranes, and quite intact. On examining the uterus I could not find any sign of rupture, but such may have occurred, as decomposition was far advanced.

Case 2. A hunter colt, with a very large umbilical hernia which had been previously operated on by quacks on two occasions.

I cast the animal under chloroform, and having disinfected the part, opened down through the sac until I could see the bowels. I then dissected out the sac, and having serrated the inside of the internal abdominal ring, sutured the edges of the ring together with strong eucalyptus tape, one continuous suture. I then removed portion of the outer skin and sutured the edges together, when I allowed the animal to rise. But much to my surprise, on the colt standing up the sutures evidently burst, and about two feet of bowel appeared,

hanging pendulous. I quickly cast the animal, disinfected the exposed bowel and returned it, put in interrupted sutures in the abdominal wall, much deeper than the previous ones, and then applied a large wooden clamp to the outer skin. This, I am pleased to say, had the best of a result, the whole hernia entirely disappeared.

I record this case as I have been most unsuccessful with umbilical hernia, having had a number of cases of tetanus following, also cases where the internal abdominal ring did not close. But most of my failures have been in three or four year old horses, and I shall be pleased to hear from the members the most satisfactory way of dealing with the cases.

Case 3. A valuable hunter, about seven years old, belonging to a penurious client, who, having occasion to move his furniture from an old residence about nineteen miles away, thought the cheapest way was to employ his hunter, which had previously been in harness. Borrowing a cart he sent his hunter for a load of furniture, and while the cart was being loaded the horse had a feed of oats, bran, and chopped hay. The driver then started on his way home, and when about three miles from home, the horse stopped and refused to go any further. He was sweating profusely, was taken out of the cart, and walked in. I saw him about twenty minutes after his return. He was standing in his stable with all his legs propped out under him. Head down, and quite wet and cold with perspiration. Pulseless and no rise of temperature. I diagnosed the case as rupture of the bowels. The horse died in about three hours. Post-mortem: Rupture of stomach.

I bring forward this case as this horse never at any time showed signs of vomiting.

Case 4. A bay mare, about seven years old, working at carting the previous day.

I was called to see her early in the morning, the owner stating she was sitting on her haunches trying to be sick. On arrival I found the mare as described by owner, and it was very difficult to get her on her feet, which, however, we eventually did, but she soon returned to her old position. I gave her a hypodermic of strychnine gr. 1 and repeated same in about two hours, when she appeared slightly better. After about three doses this mare stood up and began to look for food, and ceased her attempts at vomiting, and next day was perfectly well. I may mention her pulse and temperature were normal throughout.

Case 5. A valuable hunter gelding, five years old, lame near hind stifle, which was dropsical. This had been blistered about four times without any improvement. I passed a needle into the dropsical swelling, and drew off about two glasses of fluid. I then injected tinct. iodine, half an ounce, and repeated same in three weeks. The horse was in great pain for about two days after each injection, but after about three months on grass he became perfectly sound, and remained so, hunting up to date, and all the swelling has disappeared, so that the owner refused a very large price for him.

Case 6. A hunter gelding, aged, lame on near fore leg for about three weeks when I was called to see him. I examined the leg carefully but could not find anything to account for the lameness. I tried the foot without finding any evidence of lameness, but was of opinion, as I told the owner, that the horse was lame in its foot, so applied a blister around the coronet. Saw him in about a fortnight, but could not determine actual cause of lameness.

Lameness in foot not being sufficient for the owner, I tested the horse with a hypodermic of cocaine, which proved my case. The owner now wished to have the horse unnerved, but I postponed the operation to the autumn when he would be required for work; but dur-

ing the summer in a shed (being summered in) he got inflammation of the bowels and died. The owner sent me his foot, in which, on sawing down vertically, I found a long thorn which had gone through the coronary band, and with the repeated blisters had grown with the horn about one-third way down the hoof.

An animated discussion followed, in which all the members took part.

The proceedings terminated with a hearty vote of thanks to Mr. Nolans for his excellent paper.

The Queensland Horse Industry.

About ten years ago a Royal Commission was appointed to consider, take evidence, and report as to what steps could be taken through the medium of legislation, and in other ways, to improve the horse stock of Queensland. High class stud stock has been imported by the Government, and the examination of stallions by veterinary inspectors, in connection with their place upon the show grounds have been mainly the efforts made to assist the progress of the industry. The issue of new regulations in Queensland by the Stock Department in reference to the examination of stallions may not only be an attempt to create uniformity of action with respect to them in the Commonwealth, but to further the general improvement of horse-breeding in the State. No subsidy is to be given to any agricultural society that makes an award to an entire horse, three years and over, that does not carry a certificate of soundness, provided a parade of stallions has been held.—*Horse and Hound*.

Administration of the Cowsheds and Dairies Order.

The following letter has been forwarded to us by a practitioner in Ireland with a request for publication in our pages. We understand that it has not appeared in the *Irish Independent*.

To the Editor of the *Irish Independent*.

Dear Sir,

A startling heading, i.e., "Loathsome conditions," under which you report some remarks of Mr. T. W. Russell, M.P., caught my eye in to-day's issue.

Surely such a condition of affairs cannot have been such a terrible surprise to either Mr. Russell or most of the heads of our public departments who must be quite aware that this is rather the rule than the exception.

As you will see from the enclosed card (not for publication) I reside in a fairly large provincial town, which may lay claim to possessing a good Urban Council, and are under a good County Council. Amongst other blessings we have the "Cowsheds and Dairies Order" adopted since 1908. The officials appointed, with the sanction of the Local Government Board, to discharge the very important duties under the Order were the four relieving officers at salaries of ten pounds each per annum, though we have a qualified veterinary surgeon in the town.

Although the Order is in operation for close on six years, few, if any, reports have been sent in by the inspectors, yet I venture to say, from my own personal knowledge of the conditions that do exist, we are very little, if any, better off than the state of affairs which Mr. Russell describes as "most distressing and disgusting.—Yours, etc.,

"HYGIENE."

* As Diseased or Exposed to Infection

Gelatin in Microscopical Technique.

Mr. W. Johnson, M.D. LOND., M.R.C.P. LOND., Gull Student, Guy's Hospital, contributes the following to *The Lancet*.

At the Conference of the Sudwestdeutsche Neurologen und Irrenärzte held in Baden-Baden on May 24th and 25th, 1913, Professor Edinger (Frankfort-on-Main) showed several microscopical specimens mounted in gelatin in place of the usual mountant, Canada balsam. As I have had the opportunity, while working in his laboratory, of practising this method, I append details for any who may wish to make use of it. The technique has been developed from suggestions originally made to Professor Edinger by a photographic chemist, Mr. Ralph Liesegang, and has been worked out chiefly from the point of view of utilising it for neurological preparations. It is, however, by no means confined to this particular branch, but can be applied to most pathological work.

Sections may be cut by any of the usual methods—viz., freezing, paraffin, or celloidin. They can then be stained in the ordinary way, and all stains are available with the exception of those which can be extracted from the tissues by immersion in water. This group of exceptions is not large, but, unfortunately, it includes Nissl's method and all others in which the aniline dyes figure. Efforts which we made to fix these dyes in the tissues—as, for instance, by the use of solutions of varying strength of ammonium molybdate—preparatory to placing the sections in water, have proved unsuccessful. Further work may possibly overcome this difficulty.

The staining process completed, the section is put into water and is now without further treatment ready for mounting.

A few essentials must be noted. Firstly, the gelatin solution must be freshly made and the best results are only obtained when the special gelatin, as used for photographic plates, is employed. Of this, 10 grm. are taken and allowed to soak for two hours (preferably overnight) in 100 c.c. of distilled water. When about to be used this solution must be warmed to a temperature of 50° C. by means of a water bath in order to render it sufficiently fluid. It is advisable to filter it beforehand, also at this temperature.

As much of this warm solution is then gently poured on to the slide as can be put on without any overflowing. It is important to pour on as much as possible in order to get a sufficiently thick film of gelatin in the final result. When large sections are being treated it is better to keep the slide on a warm stage, and in the case of frozen or celloidin sections to pour on a thin layer of the gelatin solution first before putting the section in position on the slide. Larger sections still can, with profit, be immersed in the solution for a few minutes beforehand. The preparation is now left exposed to the air, and in the course of a few hours the water evaporates and one is left with the slide covered with a fine transparent film of gelatin in which the section is embedded. This film behaves in every particular like the gelatin film on a photographic plate. It is intensely hard, resists scratching, and can be packed face to face with other specimens without involving the risk of finding them glued firmly together, as is the manner of Canada balsam. Under the microscope a perfectly clear picture is given, and if necessary cedar-wood oil, for oil immersion purposes, can be used.

The great advantage of the method is the economy of time and material which results. There is no tedious transferring from dish to dish for the processes of dehydrating and clearing. Thus alcohol, xylol, Canada balsam, and coverslips are entirely dispensed with, and in addition one does away with the danger of injuring

large brain sections by too much handling. Apparently specimens will keep indefinitely. Weigart-Pal preparations—for which the method is eminently suitable—have been preserved for three years. Serial sections, which require large slides and coverslips, lend themselves to this manner of mounting. Finally, perhaps, botanists may find here a useful servant. Their chlorophyll specimens, being untreated by alcohol, are able to retain their pigment unaltered, and so can be mounted in the natural state.

Cheques endorsed "Hunting Memorial Fund" and crossed "The London, City and Midland Bank, Ltd."

Regulations made to govern importations of meat in the United States provide for certification as to ante-mortem and post-mortem inspections in the countries in which the animals are slaughtered. In addition the meat will be inspected by the Department of Agriculture at ports of entry, diseased or otherwise harmful meat being liable to rejection. Afterwards, if sent to packing houses, the meat will come under the inspection regulations applicable to those places. The report of the Bureau of Animal Industry, referred to no less than 792 packing establishments, and hence has surprised many people even in the United States.—*Live Stock Journal*.

Original articles and reports should be written on oneside of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

VOL. XXVI.

FOOT-AND-MOUTH DISEASE.

During the last few days, the position as regards foot-and-mouth disease has become ominous. Disease has been found among several cargoes of animals shipped from different Irish ports to England, and on Thursday was confirmed at Lowfell, near Gateshead, Co. Durham, so that we may possibly be on the eve of another serious epidemic.

We know that we have machinery and men upon both islands to deal with the disease: future outbreaks can be quelled, as we have quelled many past ones: but the existing arrangements do not protect us from importations of Continental infection, which are increasing in frequency and it is well that the English and Irish Departments of Agriculture intend to co-operate in an enquiry in this direction. The question of "How we import infection"? is the most serious practical problem the disease offers to us.

It is not impossible that the present outbreaks may have arisen from the simultaneous landing of infected material from the Continent at several Irish ports. Two other facts may be open to more than one explanation. One is that the importation of infection is more common both in Great Britain and Ireland than it used to be. The other is that Ireland, which for many years was certainly less exposed to infection than Great Britain, now seems to be almost more liable.

THE VETERINARY SURGEONS ACT AMENDMENT BILL.

Our Bill was re-introduced to Parliament on Wednesday last, and read a first time. Unfortunately it took a low place in the balloting, and seems to have little chance of becoming law this Session. How many more years it will have to wait before it even receives consideration by the Legislature it is impossible to say; but unless something happens to relieve the present Parliamentary congestion, it seems quite possible that we may be forced to a voluntary subscription to keep afloat till the measure is passed. Our capital will maintain us for a few years yet, but not for many.

ELECTION TO COUNCIL, R.C.V.S.

The following are the names of those gentlemen who have been nominated for the election in May:—

ABSON, J., Sheffield	MASON, A. W., Leeds
BANHAM, G. A., Cambridge	SHIPLEY, W.,
BRITTLEBANK, J. W.,	Gt. Yarmouth
Manchester	SUMNER, H., Liverpool
HOWARD, P. J., Ennis	TOOPE, T. C., Dover

Col. F. Duck, Messrs. F. T. G. Hobday, and J. S. Lloyd have not been nominated, and, presumably, do not seek re-election.

NOTE ON A METHOD OF DIFFERENTIATING TUBERCLE BACILLI FROM THE MORE COMMON ACID-FAST FORMS.

The chief difficulties met with in determining the presence of tubercle bacilli in milk and excreta is the presence of other acid-fast organisms, *e.g.* Timothy Grass bacillus, dung bacillus, and butter bacillus. Stained in the ordinary way these organisms, as we all know, show certain differences both microscopically and in culture; for example, the tubercle bacilli is inclined to be slightly curved, whereas the others are shorter and thicker. But the following method I found, from a large number of examinations I made, to be of the greatest assistance in differentiating the tubercle bacillus from the other "fast" bacilli mentioned.

I make my films and smears in the usual way, care being taken to spread the material uniformly and thinly. They are then stained with hot carbol fuchsin, the films are then immersed in boiling water for two to two-and-a-half minutes without being treated previously with any decolourising agents, such as 25% H_2SO_4 . The slides with films of Timothy Grass bacillus, dung bacillus, and butter bacillus thus treated were found to be decolourised, but the tubercle bacillus retains its stain even after 2½ minutes immersion. In some of the slides I met an occasional tubercle bacillus even after boiling for three minutes. If a film of milk treated in the same manner and boiled from two to two-and-a-half minutes still shows stained bacilli, these may be safely be put down as tubercle bacilli.

In the initial experiments I made my films from cultures of Timothy grass bacillus, dung bacillus, and butter bacillus, grown on glycerine agar. In making films from cultures of these three organisms it is better to make an emulsion in watch glass, otherwise the film would be too thick.

G. GAIR, M.R.C.V.S.

Conon Bridge, Ross-shire.

In Aberdeenshire and Kincardineshire a disease has been discovered among Irish cattle which were sold in these counties in November or December. Mr. William Brown, M.R.C.V.S., lecturer in veterinary hygiene, Aberdeen College of Agriculture, has been consulted by veterinary surgeons on the matter, and he states that the disease is of the nature of intestinal catarrh, and is contagious. A high mortality is recorded, 95 per cent. of animals attacked dying. The disease is prevalent at a number of farms in the Buchan district of Aberdeenshire, where Irish cattle had been bought in. Fifteen animals have died, and there are a number suffering from malignant catarrhal fever.

ABSTRACTS FROM FOREIGN JOURNALS

BOVINE TRAUMATIC PERICARDITIS—APPARENT RECOVERY.

Prof. Moussu records (*Recueil de Méd. Vét.*) an observation of a bovine animal which showed the classic symptoms of traumatic exudative pericarditis. At the moment when a fatal termination was expected, a notable improvement took place; and at the end of a few days the only symptom that remained was an obstruction of the jugulars. The animal had been purchased for the operative practice of students, so a post-mortem examination was made. The foreign body, which undoubtedly had been small, was not found. There was a fibro-lardaceous connection uniting the reticulum to the point of the pericardium, and a voluminous abscess outside the latter. Moussu supposes that the foreign body had only grazed the pericardium without infecting it, and that the exudative inflammation which had been the consequence, and which had manifested itself by the classic symptoms of traumatic pericarditis, had completely disappeared. This explains the "apparent recovery of a traumatic pericarditis.—(*Annales de Méd. Vét.*)

BOVINE TUBERCULOSIS IN MAN.

Le Mouvement Hygiénique has published the results of an extensive inquiry into the characters of the bacilli expectorated by phthisical patients. A large number of these patients had been working in the country, and had had opportunities of becoming infected by the bovine bacillus. Up to the present the inquiry has embraced 147 cases, and in 145 of these the bacilli found have been human ones of pure strain, while in the other two cases a mixture of human and bovine bacilli was present.

The inquiry was extended to cases of human tuberculosis other than phthisical ones, and also to animals. In non-pulmonary cases of human tuberculosis, the influence of the bovine bacillus was more important than in phthisis. Of 35 non-pulmonary cases, 29 yielded bacilli of the human type, and six those of the bovine type. Three of the latter were cases of cervical and abdominal tuberculosis.

Of 28 cases of lupus, 24 yielded human bacilli, three bovine bacilli, and one showed the two types at different places.

Tuberculous cattle, pigs, goats, and horses were examined, and in each case the bovine bacillus was found. In the dog, on the other hand, the human bacillus was found twice (in pulmonary lesions), and the bovine bacillus once (in lesions of the mesenteric glands.)

The significance of these results is clear. They indicate that direct infection between human beings is by far the most frequent and the only serious source of human tuberculosis. Benign forms of tuberculosis may nevertheless be contracted from the bovine bacillus, and these represent about 20 per cent. of the cases of human tuberculosis.—(*Annales de Méd. Vét.*)

JENSEN'S SERUM AGAINST PURPURA HÆMORRHAGICA.

Prof. Fröhner, of Berlin, has published (*Monatsschrift für Prakt. Tierheilkunde*) his experience of the Danish Polyvalent serum against purpura hæmorrhagica which has been introduced by Jensen. This serum is composed of a mixture of ordinary anti-strangles serum and of specific serum obtained by repeated intravenous injections of several varieties of streptococci isolated from horses affected with purpura hæmorrhagica.

The serum is injected intravenously. On the first day of treatment, a dose of 200 grammes (about 6 2/3 fluid oz.) is injected. Half this dose is given on the second day, and, in grave cases, this smaller dose is repeated on the following days.

Fröhner has treated twelve horses with this serum, and obtained nine recoveries, representing a proportion of 75 per cent. As the mortality in purpura hæmorrhagica is generally from 40 per cent. to 50 per cent., Fröhner attributes his favourable results to the employment of the serum. He regards it as a powerful curative remedy, possessing specific properties.

The price of the serum is 35 marks per litre.—(*Annales de Méd. Vét.*)

DRUGS FOR HYPOTENSIVE MEDICATION.

Dr. Felix Dossin, of Liège, has published (*Arch. Int. de Pharm. et de Thérapie*) the result of researches which he has undertaken upon drugs having a hypotensive effect, with special reference to the constancy and duration of their action. The most serviceable drugs he has tested are sodium nitrite and trinitrin (nitroglycerine or glonoin).

He finds that sodium nitrite possesses the properties of constancy and long duration of its action. The fall of blood pressure which it determines is always produced in the dog, as soon as a dose amounting to 3 centigrammes to each kilogramme of the animal's weight (= about 6-13th grain to 2-2 lb.) is administered. The blood pressure, when once lowered, remains low for a considerable time—from two to two and a half hours. This action is always marked and prolonged, whatever the channel by which the drug is administered may be. When the drug is given by the stomach, a stronger dose may be employed, as that is the case with most medicines.

The toxic dose is double the therapeutic dose. The toxicity of the drug is therefore relatively high, but it is possible, as is seen to be the case with other drugs, that the active dose may be lowered in the case of a pathological condition, in which hypertension exists.

The fall of the blood pressure results from a vasodilatation produced in the vascular territories of the limbs, by the action of the nitrite upon the vascular walls. The acceleration of the heart's action which accompanies it depends partly upon an excitation of the accelerator centre of the heart, and partly upon an automatic action of the fall of blood pressure upon the moderator centre of the heart.

Trinitrin also possesses a valuable hypotensive action, but one of a shorter duration than that of sodium nitrite. Given by the stomach, the results are less marked and more inconstant than if given hypodermically.—*Annales de Méd. Vét.*

W. R. C.

Dipping and Disease.

The Daily Leader of British East Africa publishes several columns on this subject. They say "We have discussed the question with the C.V.O., Mr. R. J. Stordy, who, with his usual courtesy, has given us a very clear statement as to the present position."

"It has been stated that the soil taken into a dipping tank by the cattle will prove a great hindrance to successful dipping operations because the iron in the soil combines with the arsenic contained in the dip to form an insoluble compound, or by the process of absorption—the property possessed by certain substances of taking up a liquid into their pores, in other words the physical retention of the arsenic—the strength of the bath is materially reduced. The soil element has been proved to be a much less serious factor in the weakening of the dip than the chemical process of oxidation.

The arsenite of soda—the principal ingredient of the dipping fluid—is more destructive to tick life and more absorbent than the arsenate of soda. The oxidation of the arsenite to arsenate has been demonstrated to occur in the dip, and to be due to the growth of bacteria in the dipping fluid. When a tank is first filled and cattle passed through it the bacterial element is introduced, oxidation commences, and it has been shown that the rapidity and continuation of oxidation varies in different parts of the country; the colder districts being less affected than those possessing a high temperature.

It has now been demonstrated that when a dipping tank has been in use for some time another bacterium is developed which has the power of reducing the arsenate back to the arsenite. One bath was oxidized to the extent of 43 per cent. of its arsenite before reduction commenced; another was oxidized only to the extent of 15 per cent., while in a third, no sooner had oxidation commenced than the reducing process set in.

The experiments recently carried out by the Government Analyst go to prove that heat encourages oxidation. There may, of course, be other factors. This oxidation of the arsenite to arsenate is no new discovery. It confronted the scientists in South Africa, and in our hotter climate we must anticipate an exaggeration of this chemical action.

It is the intention of the Government to appoint a chemist to work in conjunction with Mr. Kirkham, whose sole duty will be to advise farmers in regard to the adjustment of their dipping fluids. Experiments are meanwhile being conducted with a view to obtaining a germicide which will prevent bacterial growth in dipping tanks.

"There is nothing insurmountable in this adjustment of the bath," said Mr. Stordy emphatically, "The difficulty has been overcome in South Africa just as it is being overcome in British East Africa."

While regular dipping will ultimately suppress East Coast fever, farmers must not expect to eradicate the disease after two or three months' dipping, and an occasional death from the disease may occur. It will probably take the East African farmer a year, dipping at three days' interval, to clean his pasture land of infected ticks.

On the highly infected velds of South Africa, referring more especially to Swaziland, the heavy mortality there has been reduced to something like 5 per cent. In

this native territory there are 27 tanks in use. The Swazis fully appreciate the value of dipping, and every week 27,000 head are passed through the tanks, 18,000 every five days, and 9000 every three days.

In Zululand 250 tanks are in working order and the natives are dipping their cattle, and pay for the erection of dippers and the dipping.

It is hoped that the natives of East Africa will follow suit, and during His Excellency's recent tour through Masailand several sections of Masai requested that a dipper be placed at their disposal. A dipping tank has been completed at Ngongo Bagas, and within the next few days the Masai will be instructed in the dipping operation.

In Natal there are 1,500 tanks in use to-day, and to show the confidence which the results of dipping have inspired in South Africa one has only to look at the large and valuable consignments of breeding stock which have been imported to the Union from Britain during the past year.

There are, of course, many arguments advanced against the adoption of a dipping scheme for this Protectorate, foremost among these being:—

1. Trespass of cattle from Native Reserves.
2. Infected areas which have become enzootic (endemic.)
3. Bartering susceptible cattle in Native Reserves.
4. Presence of big game in settled zones.

With the establishing of a general dipping scheme greater supervision over native reserves will be made possible and, at the same time, the stock owner who dips is placed in a position to prevent, either the introduction of disease, or if it is introduced, to eradicate it with the minimum of loss.

In regard to the enzootic Coast fever areas it should be pointed out that the condition is maintained, in the majority of instances, by an annual mortality among calves, frequently adults—a mortality often running to 60 and 75 per cent.

To keep up the infectivity of the testing area at Kamite 49 susceptible adults and three calves have been sacrificed during 1913.

Therefore to allow of his young stock contracting the disease during calldom, a farmer must preserve his pasture lands in a high state of infection, and to do so means considerable disease and death among his young animals.

"The death rate," said Mr. Stordy, "means the difference between success and failure in stock raising, and if enzootic areas are to be maintained at such cost, I fail to see how cattle raising can be a profitable proposition, how farms can be stocked up or how the grading up of cattle can ever be attempted, especially when we remember that there is no natural immunity to East Coast fever; that is to say that the progeny of animals which have suffered from the disease are not born with any resistance to East Coast fever, but must acquire their immunity by passing through an attack of the disease."

It has been proved that cattle, drawn from Borana, Southern Abyssinia and Jubaland, are highly susceptible to Coast fever infection, therefore, if we are ever to hope for the full benefits accruing from this importation—11,263 were imported during 1913—farmers must dip.

With reference to the third argument, "I am of the opinion," said Mr. Stordy, "that if a man advances first the argument that he is unable to stock up, and then when invited to co-operate in a dipping scheme for his own and the country's benefit, states that dipping would render it impossible to get rid of his female stock—the very foundation of his herd—then such a one is deserving of little consideration."

Alluding to the fourth argument, the presence of game in the settled areas, Mr. Stordy said, "I am often

confronted with the statement that unless the Government is prepared to dip the game it is useless for the farmer to dip his cattle."

Apart from the zebra, which may be implicated in the propagation of equine tick fever, it has yet to be demonstrated what other species, if any, harbour tick-borne blood parasites noxious to our domestic animals. So far as East Coast fever is concerned, field observations point to the presence of big game in infected areas as being more beneficial than otherwise, for innumerable ticks are cleansed during their larval and nymphal stages while engorging on the unsusceptible game. Again, many species of antelope do not harbour ticks owing to the secretions of their skins being repugnant to tick life.

Zebra, warthog, eland, rhinoceros, lion, and other vermin harbour ticks, but even if we got rid of all our big game we would still have the tick-infected small vermin to contend with.

If the big game are responsible for tick-borne disease in our animals, all the more reason for the stockowner to dip; if they assist, and some of them do, in the propagation of tick life still the more reason to dip, for by so doing the farmer is always safeguarding his stock and reducing tick infestation of his farm. At each dipping, hundreds of "seed" and young ticks are destroyed, and the adults are either killed at the first dipping or their vitality so impaired that they readily succumb on the second immersion.

It has been further proved that female ticks which have been submitted to the dipping fluid lay fewer eggs and the great majority of those laid never hatch out. (Some ticks are capable of laying from 6,000 to 20,100 eggs).

"I hold no brief for the game. We know it can spread rinderpest and we know that several genera propagate internal parasites communicable to our stock, says Mr. Stordy.

"The game is rapidly disappearing and as colonization extends it is bound to migrate to the remoter districts of the Protectorate, but what I do say is that the presence of game in the settled zones to-day does not hinder the farmer dipping to preserve his stock and by so doing benefit himself and assist his brother farmers in placing the stock industry of this eminently stock country on a sound foundation, which cannot possibly be attained so long as tick infestation of our animals with its concomitant disease remained unchecked."

Settlers in the Kyambu district, who have freed their cattle of ticks by dipping, have drawn attention to the fact that the tick bird (*Buphaga erythronhyncha*)—a bird which sucks the blood of engorged female ticks or feeds on the wounds of animals—has entirely disappeared from their farms to become an unmitigated nuisance to their non dipping neighbours. Most farmers are dipping for the general condition of their stock, for, apart from the eradication of Coast fever, dipping has proved efficacious in the prevention of other tick-borne diseases such as redwater, gall sickness, white scour in calves, and it has done much to stop contagious ophthalmia, check the ravages of mange, lice, and other external parasites, and has saved the farmer from considerable economic loss through the teats of his dairy cows becoming "blind" as the result of tick bites.

The South African authorities are now pressing for compulsory measures. They state:—"Helpful as isolated tanks are to the individual owners, they are yet far from conferring that sense of security to the whole community which exists where every farmer has a tank, through which all the stock are regularly passed." "It is for the backward minority that compulsion is necessary."

"It is that element of compulsion," said Mr. Stordy, "whereby we can ensure the cleaning of all travelling

stock that is essential, and by which alone freer movement of stock will be made possible."

"By the Uasin Gishu farmers' acceptance of my proposals," concluded Mr. Stordy, "the farmers' associations throughout the East Coast Fever non-infected areas of the Protectorate have given practically a unanimous vote in favour of the adoption of the scheme, and the Ulu farmers, with whom I had the pleasure of discussing the matter on New Year's day, resolved, with only two exceptions, to add their support.

"I address the Lumbwa farmers on the 19th inst., and if they accept my proposals—and I sincerely hope they will—I shall be placed in a position to inform the Government that the farming community of B. E. A. is in favour of a general dipping scheme, and to ask for the funds necessary for the erection and maintenance of dipping tanks along stock routes, in native reserves and at other convenient situations, whereby the farmer will be enabled to run his transport or move his cattle without endangering them or the stock of his neighbours."

An American Plea for Tuberculin.

"In Britain, as in America, there are divers opinions with reference to the value of the tuberculin test. In both countries there are those who look upon it as a safeguard to the stockman in the prosecution of his work, and there are others in both countries who distrust its efficacy. The latter view has arisen doubtless because frequently cattle which are pronounced tuberculous by veterinarians who conduct the tests are in many instances among the most thrifty and fleshy of those found upon the farm.

All persons who are at all informed upon the subject agree to the fact that such a disease exists among cattle. The majority of the breeders of Britain are probably committed to the view that it is not seriously harmful. Others there are who believe that its presence in a herd is a standing menace. That is the view of the writer. Experience at the Minnesota University during recent years made it plain that one tuberculous animal in a stable in the winter season, that is the season of housing, was a standing menace to all the animals housed in that stable.

The prejudice that has arisen against the value of the tuberculin test is probably based upon the fact that some animals have been pronounced tuberculous in instances in which the post-mortem failed to show any indications of tuberculosis. Now what did this prove? Simply one of the following things: First, that the veterinarians were unskilled; second, that they may have used ineffective tuberculin; and third, that they may not have been sufficiently skilled to detect the presence of the disease in the animals pronounced tuberculous. These statements are not intended to reflect upon the skill of veterinarians in Great Britain as a whole. Incompetent veterinarians are found on both sides of the Atlantic. Notwithstanding, I can name veterinarians in the United States who have never pronounced an animal tuberculous in which the post-mortem did not justify the conclusion reached.

In the State of Minnesota, in which the writer lives, the stockmen themselves—the breeders of pure-bred stock—are most anxious to have their cattle tested. They accept the fact that tuberculosis in the herd is a menace to its welfare, and they want to get rid of it. In Minnesota, dairy herds may not send milk from their untested herds to the city of Minneapolis and of St. Paul. Is there any such provision in England to protect the consumers of milk?

In a herd in the north of England we tried to purchase cattle. They were, of course, for America, where the test is imperative. Some animals were priced to us

at 30 guineas, that we greatly admired. We would gladly have paid the price, but the owner would not submit them to the test. We could not take them to America without the test. Rather than miss them we would have paid 100 gs. But, no, the test was in the way. Was not that man paying a high price as the penalty for ignorance and prejudices? It may sound well to say of the North of England the free air is unfavourable to tuberculosis, but the fact remains that free and fresh air is not a sufficient guarantee against the invasion of tuberculosis.—THOS. SHAW.

The Live Stock Journal.

CENTRAL VETERINARY SOCIETY. (NATIONAL V.M.A.—SOUTHERN BRANCH.)

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, February 5th, Professor G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book: Messrs. G. H. Livesey, J. B. Buxton, P. W. Dayer Smith, R. J. Foreman, W. Perryman, W. L. Harrison, R. Eaglesham, M. Cahill, R. A. Philp, C. H. Sheather, R. Hayhurst, N. Almond, D. Stewart, W. S. King, H. H. Morrow, H. J. Parkin, G. Dunlop Martin, Capt. C. H. H. Jolliffe, S. L. Slocock, W. R. Davis, S. H. Slocock, H. King, W. N. Thompson, and Hugh A. MacCormack, hon. sec. Visitors: Prof. Lander, Messrs. A. T. Crowther and J. T. Edwards.

On the motion of Mr. Almond, seconded by Mr. Stewart, the minutes of the last meeting were taken as read and signed.

Correspondence. Letters and telegrams were received from Messrs. J. Willett, W. Shipley, E. L. Stroud, and J. W. McIntosh regretting their inability to be present.

The HON. SEC. announced the receipt of Memoirs of the Department of Agriculture in India; "Rinderpest," by Major J. D. E. Holmes, M.A., D.Sc., M.R.C.V.S.; and a Description of the Imperial Bacteriological Laboratory, Muktesar, its Work and Products, by Major J. D. E. Holmes, M.A., D.Sc., M.R.C.V.S.

The HON. SEC. was requested to write and thank Major Holmes for the copies.

SPECIMENS.

The PRESIDENT submitted a specimen which was apropos of the discussion; it was an injured navicular bone resulting from the picking up of a nail. The horse was slaughtered after nine days. The nail entered on the outer side of the frog, about halfway between the point of the frog and the bulb. It went in about 2½ inches. The nail was only found the next day as the horse was being brought out. There was no chance of the nail having got into the foot while in the stable, it must have entered on the previous evening. The injury subsequently broke out at the inner heel, i.e. on the side opposite the point of entry. The bursa had evidently been punctured, for synovia was flowing and the soft structures, including the tendon, must have been pierced. On dissection after slaughter the pus present, which was under great pressure, spurted out about 1½ yards. The point of the nail must have injured the back of the bone, and an ulcerated track developed upwards to the left away from the point of entry. The horse had been in excruciating agony, and was destroyed as unlikely to afford a good result. He had suspected a fractured navicular bone. If there had been no infection it might have been worth while proceeding with treatment, but the best result would probably have

been adhesion of the tendon to the back of the navicular bone, and most probably permanent lameness.

Mr. LIVESEY reported a case of a foxhound bitch in whelp, the seventh case of the kind he had met with. The period of gestation was normal. Parturition begun on the sixty-third day, two puppies being delivered alive, while the third was dead. Labour pains then ceased. The speaker was called in and found the dog dull, listless, and only just able to stand, she had a woe-ful expression of face. The pulse was hard and rapid. Evidently she had more puppies to pass, perhaps two or three. On feeling the abdominal walls, to learn the position of the next puppy to be presented, he found that it had not become engaged in the pelvis. He did not know what he had to contend with. The dog was valuable, and he was urged to administer a remedy. He therefore administered a dose of pituitrin subcutaneously, expecting the almost invariable result of increased labour pains. Labour pains did not follow the injection, and the speaker made a careful examination of the general condition. On tapping the animal's sides with the tips of his fingers, it appeared that she was becoming tympanitic. The abdominal walls seemed to be separated from the viscera by a certain amount of gas. He examined, per vaginam, and with the tip of his finger just managed to locate a puppy. He then inserted long forceps, and tried to pull the puppy down into the pelvis, and so through the passage. He found this practically impossible; evidently the puppy was emphysematous and dead. A later examination of the bitch showed her to be still more distended with gas, her pulse more rapid, and general condition more serious. She seemed to be suffering from peritonitis. He could feel one puppy more distinctly than others. Judging from all the circumstances, and from the fact that the bitch did not react to pituitrin he concluded that the womb was ruptured, and, on his advice, the bitch was slaughtered. He found three pups loose in the abdominal cavity. Two were dead; one, a normal pup, had just died. The two dead ones were emphysematous. One was partly jammed in the pelvis. The womb had given way at the left horn, close to its junction with the body of the uterus. The right horn was black, and almost ready to come away under pressure.

In cases like this, it was not always easy to diagnose rupture of the womb until peritonitis had set in and there was distension of the abdomen. When he first saw the bitch, distension had hardly commenced, but in two or three hours it was most marked. Young practitioners might overlook the condition, and endeavour to get away the puppy. Rupture of the womb might therefore reasonably be diagnosed in cases where the organ failed to respond to the administration of such a drug as Pituitrin, and where, on feeling the abdomen, the puppy was more clearly felt in the abdominal wall than in a normal case of parturition.

In reply to the President's enquiry, Mr. Livesey said that he thought the rupture might have occurred through over anxiety on the part of the kennelman; they got into the habit of kneading the sides of the animal.

Mr. ALMOND submitted instances of dilated œsophagus in a horse, this dilation being distinct at the entrance to the thorax. These cases were unique in his experience, and he would seek to know the termination. No inconvenience was caused to the animal, which did its work. In one case the horse was with its owner for thirteen years, and was never in trouble. In another instance the horse was six years old.

On the motion of Mr. Sheather, seconded by Capt. Jolliffe, this question is to be put on the agenda at the next meeting.

"TRAUMATIC MALADIES OF THE FOOT OF THE HORSE."
ADJOURNED DISCUSSION.

Mr. ALMOND thought that the sloughing which followed treads, and was more or less circumscribed and deep, was due rather to infection by the bacillus of necrosis than to the original injury. It was, he believed, closely allied to the necrosis found in the mouth of the sucking calf—localised, deep, necrosed patches, these usually yielding to the application of common salt. He considered that Mr. Davis was to be congratulated on the success of his energetic, if simple, treatment of the puncture due to a fork. The injury, it appeared, was serious. The instrument must have been clean, and, moreover, sharp, to have passed through such a region without leaving greater trouble. The speaker had a few notes on the obscure and acute lameness in the hind foot, due to disease of the navicular bone. These cases gave trouble and caused doubt in diagnosis. In the first case his diagnosis was made after death. Navicular disease of hind foot was very rarely met with; in fact he did not remember meeting it until the case referred to. Two similar cases, since occurring, he had diagnosed by elimination of other causes, nothing but navicular disease accounting for the sudden onset and continuous, acute symptoms. With regard to fractures, William Hunting had pointed out that minor fractures frequently occurred within the hoof, adducing post-mortem evidence in proof. The speaker had had two cases within the last two years. One, a young animal, had shown lameness without any evidence of cause. In both cases the animals had been turned out for a period of four months, or longer, and complete recovery had been effected. Mr. Davis had raised the question whether laminitis should be included in the traumatic maladies of the foot, at the same time attributing laminitis to the absorption of poisons. If that were correct, it would not be right to make the inclusion. But the speaker did not agree that all cases of laminitis were due to absorption of poisons from the uterus or intestines. Again, the speaker held that concussion alone was not a cause of laminitis. Concussion *plus want of condition*, frequently did cause the malady. He knew cases in which horses, after standing, perhaps for a week, would be driven seven, ten, or more miles to market, and then left until the following market. Animals were almost certain, after such treatment, to develop laminitis. After summering, walking practice should be given to hunters before the hunting season, so as to avoid laminitis. He believed all practitioners would be convinced that concussion alone would not cause laminitis, but horses used intermittently and then set to heavy work were liable to laminitis from concussion.

Eating wheat alone in large quantities he regarded as a certain cause of laminitis. The horse filled its stomach unduly, and the dry grain swelled. He would not, however, commit himself to a definite statement, but he felt that some of the trouble was due to fermentation of the mass in the stomach. The cases of laminitis which arose from absorption of poisons from the uterus were among the worst of their kind; they destroyed the use of the animal finally. Mr. Davis had stated (after Prof. Pritchard) that wheaten flour gruel caused laminitis. Mr. Almond said he usually gave his horses oatmeal gruel, he had given wheaten flour gruel without causing harm, and if laminitis followed he should attribute it to a coincidental want of condition. He remembered in the "eighties," when wheat was sold at 18/- a quarter, many farmers used wheat for feeding their horses, and no evil resulted, notwithstanding that it had been damaged by the bad weather of that time. The same remarks were true of barley.

In regard to treatment, the essayist had suggested laxatives, poulticing, and casting. There was no objection, the speaker considered, in giving horses a laxative, and the poultices were useful. As to hot or cold poultices, this depended upon the stage of application; in the early acute stages he prepared warmth, and later cold. The mild stimulus of the cold might not be disadvantageous. Casting he thought very important. With plenty of room, it was rarely necessary to cast a horse more than once. The relief to the animal was generally so great that he would lie down if he could be got up, but this sometimes invited a little trouble.

The question of exercise, the speaker was unaware of anything better suited to bring about the necessary flow of fresh, and therefore reparative, blood in the inflamed foot, than a moderate amount of exercise; nothing was more curative, or essential.

Mr. EAGLESHAM much appreciated the way in which Mr. Davis had dealt with traumatic injuries to the foot. In connection with treads, which he had found common, he shared the view of Mr. Perryman—that there was always septic infection from the beginning through the tread. He agreed with the author that, in the treatment of treads, warm poultices at the onset were the most useful. He did not care much for the subsequent use of antiseptic bandages, especially in the case of cart horses. The animals were apt to rub the bandages with the opposite foot and cause irritation of the granulating wound. He had found the open wound treatment the most successful.

He was of the opinion that the case of fractured navicular bone mentioned by the author was due to an injury, probably caused through treading on some blunt object.

With regard to the treatment of gathered nails, the most important matter was the proper cutting out of the feet: Mr. Davis had great faith in injecting antiseptics into the track of the nail, but he (the speaker) believed the proper treatment was the thorough paring of the horn around the puncture. In the treatment of suppurating corns and pricks similar measures should be carried out.

In reply to an enquiry as to the proper manner of cutting out, the speaker said that in the case of a gathered nail where the frog was affected, all underrun horn should be removed. Likewise the case of the sole and where there was great lameness it was even necessary to thin the sole all over in order to relieve pressure. The after treatment was very simple poulticing, antiseptic foot baths, followed by a dry dressing, *e.g.*, Boracic acid.

In respect to shoeing feet affected with corns, he thought a threequarter bar for the inside heel a good shoe for big feet, also a threequarter shoe suited small feet very well.

Mr. SHEATHER did not think it possible to cut out corns sufficiently. In the case of pricks or binding nails the whole sole should be thinned as much as possible, and not the track of the offending nail alone explored. He was of opinion that laminitis might occur from concussion. He recalled a case of a horse operated on over 15 years ago for roaring. The horse was left in the box for six weeks. It was then taken out and galloped, laminitis supervened the same evening, and the animal had to be destroyed in a few days.

Some argument arising, the speaker declined to attribute the laminitis to want of condition alone. He argued that the condition would not have arisen unless the horse had been galloped.

In another case laminitis had been induced in a hunter in condition by galloping on frosty ground.

Mr. SLOCOCK was of opinion that laminitis should not be included among the traumatic injuries of the foot. He attributed the malady to irregular feeding and want

of condition, and it was found in horses that had been lying idle in the stable. The growth of horn was a fair indication of a horse's state of health. A horse at grass never had laminitis, the growth of horn was always good. With stabled horses that were not exercised, the faulty growth of horn came with age. In such cases there was a tendency to acute laminitis, careful feeding being necessary as well as exercise to avoid the evil. The phase of laminitis which trended towards traumatic affection was the bruising of the laminitic sole. Suppuration under the sole might arise from bruising by stones. One form of nail injury resulted from horses treading on box lids or pieces of wood having nails sticking up.

The speaker disagreed with Mr. Davis in regard to the cutting down of the frog in searching a foot, believing that the frog could be searched without destruction. The frog was a provision of nature, and there could not be a strong foot without it. The peculiarity about a horse with a frog injury was this, that there was seldom a nail in a frog without a shot joint; this knuckling of the joint occurred in 19 cases out of 20 where the nail was hidden in the last two-thirds of the frog. The horse would refuse to tread on his heel. The speaker never advocated the paring away of the frog unless he were satisfied that there was an injury. He agreed with Mr. Sheather that it was necessary to pare all round the point of entry—the whole surrounding surface, otherwise further trouble might be expected. The fracture of the navicular which had been mentioned must have been caused at some previous time. Lameness was most apparent after the animal had rested for a few minutes. The wings of the os pedis were often fractured, accompanied with suppuration of the heel, and he had had to remove the detached piece of bone before attaining any success.

Mr. Slocock was pleased that mention had been made of the sudden lameness. An injury might have been known to have been caused for a week or more, followed by sudden lameness during a journey. It seemed to the speaker quite easy to imagine, yet veterinary surgeons differed in giving evidences in these cases.

[Some discussion here took place between Mr. Sheather and other gentlemen as to the probability of laminitis arising from concussion independently of the want of condition in the horse.]

The PRESIDENT heartily congratulated Mr. Davis upon his presentation of the paper. It was the practical kind of paper that always aroused a good discussion. He (Prof. Wooldridge) was of opinion that laminitis, where two feet or more were affected, was not a traumatic affection, at all events as he understood the term traumatic. Traumatic affection implied affection associated with a trauma (or wound). In the case cited, he would have ruled out the idea of traumatic affection. Actual traumatic laminitis was to be met with, where the inflammation of the sensitive laminae was due directly to some injury or violence. Was it due to concussion or to absorption of toxins from the intestine? He would at once admit that he did not know the cause of laminitis. Mr. Sheather had shown that concussion could certainly in some cases be the exciting cause, whatever might be the predisposing cause, as bad feeding, etc. In the instance mentioned, concussion was the exciting cause. In other cases it could occur without any concussion, as for example, when secondary to metritis. He considered that Mr. Davis's method of casting the horse in the box was one which would commend itself to the profession. The speaker had himself rarely found it necessary to cast a horse for laminitis; if the horse could support himself fairly well he put him in slings, it answered equally well and reduced the chance of bedsores, but should the animal not support himself comfortably in slings they should be

removed, when he would, in most cases, lie down without the need of casting.

Mr. Davis had suggested that the bedding should always be left down in the cases of laminitis, and the speaker agreed, but added that the bedding should consist of short litter, long litter was liable to get entwined round the animal's foot and cause inconvenience. With short litter there was a certain amount of distributed pressure over the sole and frog, which in some cases was desirable. In that respect the treatment would fall into the same category as that suggested by Mr. Perryman when he said that the foot should be reduced and the wall pared away. The President agreed that the walls should be reduced as far as the white line, but not farther. The sole should be thinned to relieve tension and pressure, as suggested by Mr. Sheather. In regard to medicine, he (Prof. Wooldridge) could not understand why Mr. Davis preferred oil; personally, he avoided drenching a horse having laminitis if he could help it, using, in preference, a full dose of aloes. Although some of the Fellows objected to aloes, the speaker had not seen any evil effects from its use. Either a full dose of aloes, or a half-dose of aloes with a full dose of calomel he considered the best thing in the first instance; in any case the bowels should be well opened.

In the treatment of laminitis no reference was made to hypodermic injection of adrenalin over the plantar arteries. The speaker, in cases of laminitis, injected as much as 40 minims of adrenalin (1-1000) diluted with the same amount, or twice that amount of normal saline solution. By means of this injection over each plantar artery and throbbing was reduced, also the excessive congestion of the sensitive lamina. By reducing the congestion, the danger of extravasation from the vessels, which causes separation, was diminished, and the prospect of the descent of the pedal bone, which followed the separation, reduced.

On the question of nails in the foot, the specimen he had shown would illustrate his unfortunate experience in that respect. He considered it a mistake to pare out the nail track immediately. The first thing to do, especially if the nail had been embedded a long time, was to procure a strong disinfectant—he preferred equal parts of carbolic acid and glycerine—then remove the nail, and pour the disinfectant into the nail track before any cutting was done. Immediate cutting introduced dirt and other material into the track, ruining the possibility of disinfecting the track. Subsequently the nail track should be pared out, and a compress packed over it. If the injury had been neglected for a long time, and suppuration occurred, the necessity for opening up the track was the greater. In such a case as he had submitted, however, in which he was not consulted until nine days after the occurrence, even the treatment suggested would have been useless, as the nail had passed right through into the navicular bone itself. Slaughter was the only possible solution.

Mr. Davis had carefully described the operation he thought necessary in some cases where the navicular bursa was affected, of reflecting the frog, cutting the tendon, and scraping the area of the os pedis where the tendon was inserted. He recalled that Prof. Macqueen had, in the course of a lecture, expressed the opinion that the operation was an insane one. It was certainly a heroic operation, but sometimes it was difficult to distinguish between heroism and foolhardiness.

As to corns, he differed from Mr. Davis in the latter's disposition to attribute all corns to shoeing for the reason that corns were not found in unshod horses. Mr. Willett had seen them in unshod feet. While agreeing that shoeing might be responsible for corns in many cases, the speaker considered that in many more shoeing had nothing to do with it; in some instances it was due to contracted feet, in which normal expansion of

the hoof did not take place when the weight was brought down on the foot. The result was pinching and bruising of the sensitive structures at the place where expansion should be at its greatest; that was responsible for the bruising of the sole and laminae in the heel which was designated "corn." Mr. Perryman had enquired whether treads were due to actual injury or to infection. The President believed the ill effects of treads to arise in both ways. Direct injury or violence was sufficient to impair the vitality of the tissues without infection, causing them to die and slough; this was followed by an open wound some days later. In other cases a minor injury to the coronet, arising from other causes, had become infected, when a similar condition was produced. This was called a tread, but probably was no such thing. In some instances necrosis, due to the necrosis bacillus, occurred; these were, indeed, the most painful conditions of the coronet that he had met with. Metastasis might also take place, the horse finally dying from necrotic lesions in the lungs due to infection of the blood stream from the coronet.

He joined issue with Mr. Almond on the question of the conditioning of hunters being directed solely, or even mainly, to the prevention of laminitis, taking the view that it was less a matter of the condition of the foot than the condition of the heart and lungs; congestion of the lungs being more to be feared when hunting with a horse out of condition. Then, the inability of the heart to cope with its work led to the blood being imperfectly driven through the lungs, with the result of acute venous congestion.

REPLY.

Mr. DAVIS said he thanked the Fellows for the compliment paid to his notes in the adjournment of the discussion. He attributed it to the choice of the subject rather than to any merit in the notes themselves. Mr. Perryman and several other gentlemen had contended that violence was not the cause of treads, and that the only determining cause would be the scratch. The horse scratched the skin about the coronet, and the part became infected with microbes. He would ask why this did not occur higher up, on the leg? Why only at the coronet? He believed that treads were due to violence. The animal began to scratch, and, liking the sensation, continued, getting more violent as he went on, as Shakespeare said, "Appetite grows with what it feeds on," and the more he scratched the more violent his action.

With regard to the treatment of treads, the speaker did not advocate poultices, preferring the application of cotton wool with an antiseptic, bandaged on and kept as clean as possible. In all cases where there was a suppurating wound of the foot he would argue in favour of antiseptic treatment.

He did not believe that laminitis was ever purely a traumatic disease. Prof. Wooldridge had limited the word "traumas" to wound, but any injury to the body due to violence is traumatic—results of concussion for instance. As stated, in the speaker's opinion, laminitis was never due to concussion; if it were, why did it arise by absorption of toxins from a wound? Sir John French had stated, during the Boer war, that horsemastership should be taught, so that there should be no injudicious feeding, producing laminitis. Mr. Mackintosh had told the Fellows that he was in charge of about 900 horses, and did not, save very rarely, find a case of laminitis, notwithstanding that the animals were very hard worked. Although Mr. Mackintosh could not account for the fact, he (Mr. Davis) attributed the immunity to the circumstance that Mr. Mackintosh fed his horses on oats and hay. He had not seen a case of laminitis for six months, but where he used to live he had fifty cases for every one he had now.

He remembered being called in to a mare that on returning from plough was found to be ill. The mare was hanging back in the stall and breathing rapidly, the temperature being 104°. The artery at the jaw was suspiciously hard under the finger. He diagnosed laminitis, and gave the mare a dose of his despised oil. He went home, but was sent for again. This time he found the fellow mare, which had been hard at work ploughing all day, in the same condition as the first one. He suspected bad feeding, but the owner replied that both animals were fed on oats and hay. Investigation, however, showed that the mares had been given wheat. The ploughman had stolen a sack of ground wheat meant for the bullocks. The laminitis in these cases could not be due to concussion, as the mares had been ploughing on soft ground.

The speaker then narrated the circumstances in which a chestnut horse and a black mare had been let by a jobmaster to carry twelve persons a journey of thirty miles. At a certain town the horses were taken out, and the man in charge found that the chestnut horse refused to eat, and, to tempt him, procured a shillings-worth of flour which he mixed with cold water. The horse, which had been purged, still refused the food, and, in order not to waste it, the man gave it to the black mare. The chestnut horse recovered himself during the homeward journey, but the black mare broke down on reaching home, and had to be carried into the stable and developed acute laminitis. Another instance. He had had at New Orleans the veterinary charge of horses collected for shipment to Africa in the Boer War, after 5000 horses and mules were in the yards. They were fed mainly on American bran (4/5). Cases of laminitis were always occurring, yet the animals were kept in covered yards or at pasture. These instances could not be due to concussion. He made strong representations for alteration of rations, and such alterations were, after a time, effected, when there was a complete cessation of laminitis.

In regard to treatment, Mr. Davis differed from Mr. Sampson and Prof. Wooldridge. In both laminitis and azoturia it was absolutely imperative to empty the bowels. The best aperient in these diseases was oil; the worst aloes. He admitted that a ball was easier to give than oil, but we were seeking an efficient remedy—not one easy to give. The dose he had given the two mares was 2 oz. of Liq. ammon. acet. conc. (1—7) put in a champagne bottle filled with oil and a similar one was left with orders for half to be given in six hours, and the rest in another six hours.

He was astonished to hear that Prof. Wooldridge and two past-presidents of that Society put horses affected with acute laminitis in slings; the object of putting them in slings was to relieve the pressure on the feet, and he considered it a great deal better that the animals should be at once put down. This, of course, did not apply to slight concussion, where the foot was a little bit sore, but to cases of acute laminitis, where the horse stood with his two fore feet advanced, as though they were riveted to the ground, and his hind legs a long way under the body, with retracted belly, accelerated breathing, dilated nostrils, and the artery of the jaw as thick as a little finger. In these cases, he believed a horse might, under rational treatment, be rendered as serviceable to his owner as before. Not so treated, the horse might be made to go in discomfort and pain for the remainder of its life. Prof. Wooldridge had said that the horse would lie down if taken off the slings, but the speaker denied this; if a horse were thrown and allowed to get up, he would remain standing. As David Harum said, "Hosses don't know but dreadful little really. Talk about hoss sense, wa'al there aint no such thing."

Mr. Almond had referred to exercise, but he (Mr. Davis) would regard as hard-hearted treatment the exercise of a horse suffering from acute laminitis. Prof. Reynolds had suggested the use of arecoline, and undoubtedly it was good treatment, but the speaker had known this to be followed by fatal results, whereas the use of oil was not. Casting by means of ropes in the way described was quite easy. He had explained it in a case of a very fine horse which had received an injury to a fore coronet. This horse had been put down twelve times in six days without bother by farm hands. That established the advantage of the method.

In connection with gathered nails, Mr. Davis related his own experience, how a nail had pierced his own foot in which he had rejected the medical man's suggestion of treatment by lotion in favour of crucial incision and antiseptics. In another case, which happened on the same day, that of a young man who, while assisting to save lives at Galveston, when it was swept by a tidal wave, met with a similar accident, lotion was applied to the injury; the young man died from lockjaw within a fortnight. It might be thought a counsel of perfection to use antiseptics to the depths of the wound in such cases. He always introduced carbolic acid, etc., into the track of the nail with a hypodermic syringe, although he had sometimes to put the horse down to effect his purpose. As to the removal of all the horn in cases where there was suppuration from pricks or in cases of corn, it was unnecessary to make such a breach in the hoof; gauze soaked in antiseptic would heal the place up, and the animal was ready for work much sooner.

POISONING BY CASTOR SEED.

A contribution on the above subject by Dr. Lander, was the last item on the agenda.

On the motion of the President, who stated that Dr. Lander was agreeable, it was decided to postpone the reading of the paper until the next meeting. The motion was seconded by Mr. Perryman.

VOTE OF THANKS.

Mr. STEWART proposed, and Mr. King seconded a vote of thanks to the author of the paper on "Traumatic Maladies of the Foot of the Horse."

The meeting then terminated.

HUGH A. MACCORMACK, Hon. Sec.

NORTH OF SCOTLAND VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A.—SCOTTISH BRANCH].

The half-yearly meeting was held in the Lecture Room of the North of Scotland College of Agriculture, Aberdeen, on Saturday, Jan. 31st. The following members were present: Messrs. Anderson, Keith; Brown, College of Agriculture; Bell, Fraserburgh; Cumming, Culter; Crabb, jun., Aberdour; Clerk, Stonehaven; Howie, Hon. Sec., Alford; Ironside, Cluny; Kerr, Ellon; Marsden, Past-President, Banff; Morrison, New Deer; Marshall, President, Aberdeen; McPherson, Huntly; McVean, Craigellachie; McBryde, Strichen; Peddie, Dundee; Sievwright, Tarland; Skinner, Old Meldrum; Sinclair, Newmachar. Visitors: Messrs. Hugh Begg, Veterinary Inspector for Lanarkshire; Alex. Johnstone, Rothie-Norman; Robson, Laurencekirk; and Lornie, Hatton.

Apologies for absence were received from Messrs. Crabb, sen., New Aberdour; and Niven, Kintore.

The minutes of last meeting as they appeared in the veterinary papers were taken as read.

Mr. MARSDEN, Banff, who occupied the chair at the commencement, said that his term of Presidentship now

closed, and he thanked one and all for the assistance and courtesy extended to him during the period he occupied the chair. They had discussed several matters of importance, and in one or two ways their position had been improved. The raising of their County Council fees had been satisfactorily looked after in Aberdeenshire, though not in Banffshire. Apparently no further action in this direction was to be taken meantime. He had great pleasure in introducing Mr. Marshall, Aberdeen, as their President for the current year, and would now vacate the chair in his favour.

Mr. MARSHALL, in accepting office, paid a high compliment to Mr. Marsden for the able way he had discharged his duties, and for helping, during his period in the chair, in carrying out several matters in the best interests of the profession. (Applause).

New Members.—The following were elected: Messrs. A. JOHNSTON, Fyvie; H. W. ROBSON, Laurencekirk; and W. S. LORNIE, Hatton of Cruden.

The CHAIRMAN hoped that the members would do everything in their power to increase the membership of the Society.

Correspondence.—The SECRETARY read a letter from the Royal Sanitary Institute asking the Society to appoint a delegate to the annual Congress to be held at Blackpool from July 6th to 11th.

On the motion of Mr. Anderson the letter was allowed to lie on the table.

THE LATE WILLIAM HUNTING.

The PRESIDENT referred in sympathetic terms to the death of Mr. William Hunting. He spoke of Mr. Hunting's high professional qualifications, and stated that it could be truly said that he lived for his fellow men. It was decided to record the Society's sympathy in the minutes, and that an excerpt be sent to the relatives of the deceased.

Mr. BEGG, Inspector for Lanarkshire, gave particulars regarding the Hunting Fund which he hoped would receive the benevolent consideration of members of the Society. He thought there was no man in the profession but who had been influenced in some way by the late Mr. Hunting.

Mr. PEDDIE also paid a high tribute to the work and worth of Mr. Hunting, and commended the Fund.

THE LATE MR. MORRISON.

The PRESIDENT also made sympathetic reference to the death of Mr. Morrison, of Rhynie, and moved that the Society's regret and loss be engrossed in their minutes, and that a copy be sent to the family.

The SECRETARY paid a compliment to Mr. Morrison's personal worth and professional capacity, and observed that he died in harness, and, sad to relate, he was a victim to anthrax.

After some discussion, it was agreed that the Society subscribe £1 1s. to the Hunting Fund, and the feeling expressed was that the members should also subscribe individually.

A letter was read from Mr. F. W. Garnett, Windermere, thanking the Society for its subscription to the International Congress Fund. He asked Mr. Howie to thank the members for their generous support.

Financial.—The SECRETARY submitted the financial statement for the year which showed a credit balance of £3 14s. 3d. He considered that if their Society was to be of greater value to the profession, they should make it stronger financially, by increasing the membership subscription, which was very low compared with similar bodies in the South. He would move at the next meeting of the Society that the subscription be raised. The report which was considered satisfactory, was adopted.

Title of the Society.—Mr. CUMMING gave notice that at the next meeting they discuss the title of the Society.

He thought that the Society's identification with the National Veterinary Association should be made more prominent.

PRESIDENTIAL ADDRESS.

W. MARSHALL, M.R.C.V.S., Aberdeen.

Gentlemen,—Let me again express to you my thanks for having elected me as your President for the ensuing year. It was with some diffidence that I undertook the duties and responsibilities of the post, especially in these eventful times. I duly appreciate the kindness and the honour you have done me, and I will endeavour, as far as in me lies, to serve your interests. I am assured of the co-operation and help of our able and valued secretary, and I also hope to receive the help and support of individual members.

Perhaps we as members have not in the past interested ourselves sufficiently, nor given what support we might have done to this important Society. Now the time has arrived when the necessity for more frequent meetings and conferences between members becomes more evident and pressing, and more especially in the North, where almost every practitioner is an Inspector under the Diseases of Animals Acts. He is entrusted with the carrying out of the work under such important orders as those for anthrax and tuberculosis, which, to be successful should be carried out uniformly, and this can only be done satisfactorily by each of us discussing fully the important details of these orders.

I am glad to see that individual societies have been linked up to one central association—The National. This will undoubtedly strengthen the profession, and we will be able to present our views and our demands to the proper centre with greater effect.

It has been the custom in the past for a new President to make some remarks on important current topics, but I may be pardoned, if on this occasion I depart from that line and make a few statements on the changes and advancements that have taken place in our work as veterinary practitioners during the past 25 years.

Going back to the old college days, we remember that the curriculum was only a three years course, whereas nowadays a crowded four years course is required of the students, and a much more searching entrance examination. Both these have served to raise the status of the practitioner. We can all look back with gratitude to the assiduity and conscientious interest of our professors, but how much more ought the student of to-day to feel grateful for the additional advantages, the greater development, and much improved equipment of the Colleges.

A few new diseases have been added to our list, but the etiology, pathology, diagnosis, and treatment of many diseases which were very imperfectly understood are now, as the result of the researches of the pathologist and the careful observation of the clinician, more thoroughly understood. Much yet remains to be done. The study of bacteriology has done much to throw light on the diagnosis, prevention and treatment of various diseases, and this science is destined to do much more. A number of diseases such as anthrax, glanders, tuberculosis, Johne's disease, quarter evil, strangles, swine fever, tetanus and various fevers have been shown to be caused by the introduction into the body of micro-organisms of the lowest class of life. Here they multiply rapidly in susceptible subjects and produce chemical ferments and deadly toxins. To Pasteur, Koch, and others we owe much for the investigation of the life history of many of these pathogenic organisms and the pathological conditions to which they give rise. Septicæmia was shown by Ogston to be produced by various organisms, and since then new treatment has

been devised. Marmorek, of the Pasteur Institute has introduced a special polyvalent antistreptococcic serum for veterinary use. It should not be confounded with the same name for human use which, although prepared in a similar manner, is derived from various strains of streptococci of human origin, and those differ from organisms of equine origin. In fact nowadays bacteriologists believe that organisms can be modified by the particular body in which they operate, and that the best results are got from vaccines and serums prepared from the actual organisms found in the lesions. The human serum has been proved to be beneficial in some forms of purpura hæmorrhagica in the horse. Marmorek serum has proved beneficial in many suppurative conditions, in erysipelas, in strangles, in which disease the substance strangaline, a particular vaccine, has proved useful. The serum is also valuable in influenza, purpura, retention of the placental membranes and in gangrenous mammitis. Vaccines made from these organisms have also proved efficacious in the prevention and cure of joint ill in calves and foals, and ought to be largely made use of.

The pathology of toxæmia is also better understood. It is the products of the organisms that enter the blood stream. There is no doubt that many of these toxins are elaborated in the alimentary canal, more especially in the case of cattle, and are accompanied by such conditions as impaction, constipation, and enteritis, and are often responsible for the brain symptoms we sometimes get in these diseases.

Some years ago Behring discovered the substance known as anti-tetanic serum, which has been largely employed, not only as a prophylactic agent but also in the treatment of tetanus. When the disease is well advanced the serum is seldom of much value as a curative, but as a preventive, and in the early stages it has given very good results. Its value as a prophylactic is so great that it should always be used when punctured and septic wounds are under treatment, or where major operations have to be performed. It should probably also be used in new-born foals on farms where the disease has previously existed.

For blackquarter we have vaccines which are of great prophylactic value. A vaccine for anthrax is also in use in countries where the disease is indigenous and wide spread, but in this country where there is no hope of stamping out the disease, as it is generally introduced by feeding stuffs and manures, it is probably better and cheaper to insure than to vaccinate.

In 1896 Bang discovered the organism of contagious abortion, and the Board of Agriculture have made considerable advancement in the elucidation of the disease. A definite diagnosis can now be made by means of the agglutination test, and the Board hope that they will soon be able to prevent this scourge by vaccination with pure cultures of the organism.

Good work has been done with regard to swine-fever, distemper, braxy, and louping-ill, although research on these is still far from being completed. Advancement of our knowledge of diseases abroad has also been progressing rapidly. To mention only one—the serum and bile treatment for the prevention of rinderpest has given excellent results.

In the treatment of all diseases we are now recognising the value of pure air, good sanitary surroundings, a plentiful supply of pure water, a suitable quantity and good quality of food, clothing, and a general attention to the comfort of the patient. This occupies the first place in the treatment of animals, more especially in the prevention and treatment of diseases of the respiratory organs. This is followed by the rational use of therapeutics, which has supplanted the empirical system. The more accurate clinical knowledge of disease, its symptoms, and their significance has enabled us to select more suitable remedies, and the results

have undoubtedly been more encouraging. In fact, nowadays, so wide is the field of the science and art of our profession in every branch that one has to specialise along whatever line circumstances dictate.

The treatment of the diseases of the smaller animals has progressed so rapidly that some have devoted their whole time to this interesting and profitable branch.

Further, the veterinary surgeon is more and more recognised in the sphere of preventive medicine, and new and important fields have opened up to us in view of the more stringent supervision of disease demanded for the protection of human and national health.

Our methods of diagnosis are becoming more exact. For example, rectal examination may yield valuable information in disorders of the organs in the pelvic cavity, and in colic manual examination enables us to discover the condition of the bowels. When violent straining occurs when the hand and arm is introduced into the rectum, it is often symptomatic of acute intestinal obstruction due to impaction or twist. In the former condition we often find the rectum dilated or "ballooned." One can readily recognise an impacted colon or tympanitis of this part of the viscera, sometimes also the presence of a calculus, and very often a twist. Rectal examination enables us to ascertain the condition of the bladder; is very valuable in the diagnosis of strangulated hernia, thrombosis of the iliacs, strain of the psoas muscles, abdominal tumours and pelvic fractures. Digital examination in dogs may reveal the presence of bones in the rectum and enlarged prostate glands.

In tuberculin, discovered by Koch in 1890, and considered at first to be a cure, we have a most reliable diagnostic agent for tuberculosis.

In 1891 the substance mallein was discovered as a diagnostic for glanders.

During recent years more and more use is being made of anaesthetics, and those who have been using those agents can appreciate the relief from pain and suffering to the animal as well as the greater facilities given to the operator. Anaesthetics are quite as useful in animals as in man, and few important operations are now performed without either a local or a general anaesthetic. Local anaesthesia produced by cocaine or eucaine, combined with adrenalin to stop bleeding, is quite sufficient for superficial operations or for operations on the limb, but general anaesthesia must be used to reduce hernia, and in all cases where one is working in proximity to important organs. I prefer to administer chloroform to horses in the standing position if there is plenty of room to allow the animal to move about. The horse seems to take it better in the standing position, and one knows that when the animal falls anaesthesia is generally complete, and the operation may be commenced.

Advancement has also been made in the administration of medicines. The older method of drenching has given way to the administration in the food, drinking water, in bolus, as electuaries, or hypodermically or intravenously, with more satisfactory and less harmful results.

Medicines calculated to bring about phagocytic action are now largely used, such as nuclein and saline solution administered hypodermically or intravenously, and have given good results. In colic, as a result of a better knowledge of its pathology, clinicians now greatly favour the use of stimulants such as carbonate of ammonia, nux vomica, and when a sedative has to be given, chloral hydrate has to a large extent taken the place of tincture of opium. Eserine, arecoline, pilocarpine, and barium chloride give good results when indicated.

The discovery of a successful treatment for milk fever by Schmidt has conferred enormous benefits on veterinary science, and on cattle owners throughout the world. Chloral hydrate and treacle were the principal

drugs formerly used, and though a few animals did partly recover, a large number lay for days or weeks, and ultimately had to be butchered. The death-rate was about 90 per cent. Compare this with the present-day treatment by injecting an antiseptic lotion, air, or pure oxygen into the udder—the death-rate is infinitesimal.

By the discovery of the Potassium iodide treatment for actinomycosis, Thomassen has conferred an incalculable benefit. In the early stages of the disease this treatment is extremely successful, whereas formerly the disease was incurable.

Time does not permit of my speaking at any length or in detail of specific changes in treatment, but it occurred to me that these few remarks might be interesting and profitable, and I hope that they will stimulate the young members more particularly to the desirable practice of recording their experiences, so that our information may be increased and our means for comparison enlarged.

In other directions great changes affecting our work as practitioners has taken place. Motor traction threatens to reduce our earnings, but new fields are always opening up to us. It seems obvious that the veterinary surgeon to-day occupies a much more important position than he did a few years ago. From the present and the past, to my mind, we have no reason to despond for the future; for perhaps at no time have the prospects of the profession been brighter, and there is likely to be much more interesting and useful work for us to do.

I should just like to say in closing that, in these times of rapidly changing conditions, it is urgently desirable that we should have more frequent meetings and discussions, so that by our collective experience and information we may be enabled to keep pace with the times and to arrive at the best and wisest decisions; and that when mutual action is required it may be united and efficient.

THE WORKING OF THE TUBERCULOSIS ORDER.

By ADAM KERR, M.R.C.V.S.

When I was asked at our last meeting to give a paper, it was suggested later on that I should take as my subject the Tuberculosis Order, and my experience in the working of it. Since the Order came in force in the County of Aberdeen on Oct. 1st, 1913, I have had a total of ten cases. Without exception these have all been cases, or suspected cases of "tuberculosis with emaciation." Out of the ten cases eight have been slaughtered and two still remain alive. The majority of these cases were reported to me either by the owner or the police. One or two of them I discovered in my private practice. That is to say, I was asked to examine the animals privately, and had no hesitation in saying that they came within the scope of the Tuberculosis Order. I have only seized one animal in the Ellon market, a milk cow, but more about her later on.

I think it will be the most profitable and instructive method if I relate to you my most interesting cases and the method of procedure adopted.

Case 1 was an aged milk cow, standing in a dairy byre, with a chronic cough, and very emaciated. The case was reported by the owner. After my examination I came to the conclusion she was tuberculous. As it was my first case under the Order, I was very anxious not to make a mistake and land the county into extra expense and myself into disgrace in the very beginning. I decided to apply the tuberculin test. She reacted beautifully, was slaughtered, and the post-mortem justified my opinion.

Here I should like to say there has been no difficulty in this case nor in the others in coming to an arrange-

ment with the owners with regard to the valuation. Of course, the animals have all been "piners" and were worth nothing more than the price of the hides.

Case 2. A nine months old calf. I was called to this case privately. The animal was very emaciated, and had been treated by me for lung trouble a few months previously, along with another one of the same age. The latter died showing symptoms of tubercular meningitis. The former apparently recovered for the time, and then gradually began to waste away. After my examination I came to the conclusion that this was a case of tuberculosis with emaciation. I could not apply the tuberculin test, as the animal's initial temperature was 105° F. The case was duly reported and the animal slaughtered. I could not have believed that such an amount of tuberculous corruption could have been present in so young an animal had I not seen it for myself. Every organ in the body was involved.

The question which puzzled me in connection with these two cases was where and how did these young animals become infected with the disease. Assuming that no calf, or at the most 1 in 1000, is born with tuberculosis, I examined the other animals, and found them apparently healthy. I began a "Sherlock Holmes" method of investigation with the owner, when he informed me that he had lost a cow last summer with tuberculosis. These two young animals had been housed beside her, and received her milk. Hence the source of infection.

Now I think this proves the soundness of the system which is being adopted by most breeders, viz., removing the calves from their mothers as soon as they are born, and only allowing contact during the times of suckling. I may say that I have tested over 60 animals during the past fortnight, some of them for exportation and some of them for the February sales, and of those herds in which this system is adopted every animal has passed the test. I am of opinion that this case refutes the statement of those who hold that we will never eradicate or reduce the number of cases of tuberculosis by simply killing off the "piners." They say these animals would have died or been slaughtered sooner or later, and that the county authorities are simply bearing the loss for the owner. Well, there can be no doubt that by killing these animals promptly we are removing one of the most fruitful sources of infection, and my experience of the average farmer is that he will hold on to his tuberculous cow so long as she is giving a supply of milk.

Cases 3 and 4 I shall take together, as they are somewhat similar. The first was a young animal about a year old, reported as a case of tuberculosis with emaciation. I examined the animal, which was very much emaciated, and with a history of chronic diarrhoea, but could not find any clinical symptoms beyond the diarrhoea. The lungs appeared healthy, the pulse and respirations were normal as also the temperature. There was no cough, the skin was soft and pliable, and the animal had a fairly good appetite. The tuberculin test was applied with negative result. I had previously informed the owner that it would not surprise me if the animal did not react as I had seen this sort of case before, and had killed them expecting to find tuberculosis of the bowels, but no tubercular lesion could be found, only a catarrhal condition of the bowels due probably to Johne's disease or some parasitic affection. The diagnosis I gave was chronic catarrhal enteritis and the case was closed.

The other case similar to this one was a five years old milk cow reported as a case of tuberculosis with emaciation. On my arrival at the farm, I discovered that the animal had been down for four days and had eaten nothing all that time. We tried to get her on her feet, but it was of no use, so I had to examine her where she lay, and you all know how unsatisfactory that is.

The fact of the matter was I could only say that there was weakness and emaciation. The temperature being normal. I tested her, giving 4 cc. and went back at the 6th hour; the temperature, however, never varied a point all the time. I then agreed with the owner to treat her. I have not seen her since, but I have seen the owner, who informed me that since she was put on to the powders she improved day and daily. She can now rise of her own accord, is chewing her cud and eating all she gets.

These two cases have brought home to me this lesson—that we must be very careful in our examinations if we are not to make mistakes; and they have also convinced me that every case of emaciation may not be due to tuberculosis. I think also where there are no positive clinical symptoms but only a marked emaciation we should safeguard ourselves against pitfalls by subjecting the animals to the tuberculin test, giving a good stiff dose—4 cc. at least, and taking the first temperature at the sixth hour; and in the case of an old animal up to the 21st hour.

Case 5. A six year old black polled cow. She belonged to a crofter, who sent me a letter to come and see his cow. I called the following day, when he told me that a country butcher had seen her in the morning, and told him that she was full of tubers, and had practically bought her for 10s. I examined her, and on the clinical examination alone I assured him that the butcher's diagnosis was right. I asked if he himself knew what was wrong with her, and also if he had read the Tuberculosis Order, and he replied in the negative. I then put myself in communication with the butcher who had bought her, and advised him to have nothing to do with her. I told him that he had bought an animal knowing her to be tuberculous and had not given any notice to the police, and so might land himself in difficulties. Needless to say he was very glad to take my advice. The animal was slaughtered in the name of the original owner and found to be full of tuberculosis.

Now, gentlemen, I wish to ask your advice on this case. Did I do right in communicating with the butcher? Or should I have told the police to serve an isolation notice on the butcher and allowed him to slaughter her at his own risk? Of course the butcher told me that he bought her simply for the price of her hide, but one never knows what might have been done with the carcase had the case not come under my notice. Taking all things into consideration I think I acted rightly, if for no other reason than that it may serve as a warning to those men who go about the country buying emaciated animals.

Case VI. Aged milk cow, seized in Ellon Market. There are cases where dealing with one's own clients one would require to be possessed of some special tact, and this is a case in point, and one which you will perhaps forgive me for quoting in full. This animal belonged to a client, and not a very good client at that—I mean financially. He had been owing me an account for over two years, and I had sent him a note the previous week to the effect that his account was considerably overdue. Well, we met accidentally in the market that morning and he paid his bill. Afterwards, I was taking a look through the market and came across this emaciated animal; I took her number, went to the salesman and asked the name of the owner. You can imagine my feelings when I was told it was my friend who had paid his account in the morning. Of course there was nothing for it but acquaint him with the fact that he would have to remove her from the saleyard, and that I would examine her later on. At first he was inclined to be rather displeased with me, but I produced a copy of the Order which I always carry in my pocket on Market days, and which I was surprised to learn he had never read or even seen before. Much against his

will the cow was taken home. I called a day or two later and made a further examination, and although I was convinced she was tuberculous, in case of error I decided to apply the tuberculin test. But he refused to allow me. He would isolate her, he would give her milk to the pigs, he would send her to Aberdeen, he would kill her himself, he would do anything except allow her to be tested. I reasoned with him, but all to no purpose. When asked what he expected for her in the market, he said £6 or £7. Well, I said, we would value her as non-tuberculous at £5, but the 30s. if tuberculous stuck in his throat, so I had no alternative than to report the case to headquarters. Mr. Murison (County Clerk) replied that if I was of opinion she was tuberculous without applying the test, I was to come to an arrangement with the owner as to the value and have her slaughtered. The terms of this letter were made clear to the owner, and after that I had no more trouble with him. The animal was tested and reacted, slaughtered, and found to be suffering from generalised tuberculosis.

These are some of my most interesting cases. I am very sorry I have not yet discovered a case of tuberculosis of the udder. I have had several cases of mastitis, and on examination have found beautiful chains of streptococci, but I have not yet found the tubercle bacillus in milk. I have even examined the milk from the previous emaciated cases, although there was nothing wrong with the udder, but the result has always been negative. I am inclined to think that tuberculosis of the udder must be somewhat rare.

I wish to ask a few questions for my own information :

(1) Are we expected to serve an isolation notice on a cow at calving with an indurated quarter and a blind teat to that quarter? I have no doubt some of you have noticed this condition among cows at the market. They are sold as correct except that they have a blind teat. As yet I have not seized them, as I saw it would be very difficult to prove. They had tuberculosis of the udder if no milk could be got from the indurated quarter.

(2) When we are called to examine an animal privately and find it is a case for the Order, who is to be charged for the first visit? The owner, or the county, or both?

(3) What exactly constitutes a set of certificates under the Tuberculosis Order?

(4) Are we expected to visit the premises afterwards and see that the cleansing and disinfection has been properly carried out?

(5) How many visits are we justified in making to take the temperature when an animal is tested? If we get a reaction on our first visit in the morning do we consider that sufficient?

DISCUSSION

Mr. HUGH BEGG, F.R.C.V.S., Veterinary Inspector for Lanarkshire, referred to the enthusiasm of the Lanarkshire County Council in stamping out disease, and mentioned that that body had put the Tuberculosis Order in operation at the earliest possible moment. He described the steps that had been taken by the Lanarkshire authority to bring the Order under the notice of stockowners. Large bills embodying the provisions of the Order were put into the hands of every owner of stock in the county. He feared that for a time little attention was paid to the Order by stockowners, for when the inspection of dairy cows was commenced his assistant and himself came across some flagrant cases of tuberculosis of the udder that should have been reported. They considered the propriety of prosecuting some owners at that period, but were averse to such a course, as he was aware of the ignorance with regard to the Order that prevailed among many stockowners. In order to bring home to stockowners

their responsibilities they circulated cardboard placards on which was printed a synopsis of the Order and these were distributed to farmers by the hands of the policemen. Those who now plead ignorance have no excuse, and the other day a prosecution had been brought, a man having been fined £2 for a contravention of the Order. Other prosecutions for failure to report are in process. He believed that would be a cheap and effective means of impressing on cattle owners the provisions of the Order—very much better than the circulation of bills which often got torn and were thrown aside. (Hear, hear). Their intention now was to make it apparent by prosecutions and the reporting of them in the press that they meant to enforce the application of the Order. Their main object to-day was to discuss the details of the veterinary inspectors' work in operating the Order. It should be remembered that while veterinary inspectors were expected to get a clear idea as to the manner the Order might be extended, or amended, if need be, they should focus their opinions as to what advice they might give to their respective local authorities; it would be well that their position under the Order should be well defined and more or less uniform. All local authorities were practically agreed that the Order was a very good initial step in the great campaign against tuberculosis. There might be different views with respect to the financial clauses of the Order. Up to now he thought the Board of Agriculture's reluctance to widen the scope of the Order had been well justified. They were entitled to demand that before more heroic steps were taken there should be satisfactory evidence that those who were to carry out these measures had gained some experience in connection with the operation of the present restricted Order. It would be the duty of all progressive authorities in the near future to knock loudly at the door of the Board of Agriculture and demand the inclusion within the scope of the Order of all open cases of tuberculosis. He referred particularly to pulmonary cases which should be included very soon. Indeed we could hardly escape recommending that all tuberculous animals suffering from pulmonary trouble should be included even though, in the absence of expectorate they could not be proved to be open cases. Many such cases were already losing flesh and no one could predict how soon they would become open cases. Veterinary surgeons should recognise that a great task was confidently entrusted to them by the Board of Agriculture, and it was for them to show their fitness for the task. (Applause). As neighbouring inspectors they should treat each other as gentlemen, and he reminded them that since in Aberdeen county the area of an inspector's private practice was not co-terminous with the district allocated to him as veterinary inspector, they should not hesitate, if need be, to report cases on their own clients' farm to be dealt with by another veterinary inspector. He thought the Aberdeen County Council was liberal in that so many were employed. They ought to avoid raising any friction that might lead the authority to reconsider the question.

Replying to Mr. Kerr's queries, he would be loth to serve isolation notices on every animal unless he had good reason to suspect that it was suffering from one of the forms of tuberculosis covered by the Order. If an inspector visited a farm under the Tuberculosis Order, the County Council would have to pay him, but if the visit was made by an inspector in the capacity of a private practitioner, then the owner of the stock was liable. It would surely be easy for inspectors to differentiate between the two kinds of visits.

Mr. BEGG explained the methods adopted in Lanarkshire in connection with the condemning and valuing of tuberculous animals. He held that as the veterinary officers gained experience the scope of the Order would be extended. Mr. Runciman had given hints that that

might be done soon. He (Mr. Begg) pointed out that in the South of England veterinary inspectors had decided that in the case of an animal valued at less than £10 no tuberculin test should be applied. He outlined a scheme which he thought would operate well in quickly ridding the herds of advanced cases of tuberculosis.

Mr. CUMMING said that strange to say he had very few piners to look after since the Order came into operation. The procedure he followed was that when called to see a case he made a valuation. The owner signed the valuation report. After he had made a clinical examination, and if necessary applied the tuberculin test, the consent of the owner was got right away. That saved reports and visits.

Mr. HUNTER said tuberculosis was a nasty thing, but he thought there was far too much made of it. He was not certain that it could be communicated from cattle to the human subject.

Mr. HOWIE gave his experience of having found two cases of tuberculosis of the udder. He had no difficulty in detecting the bacilli. He had as much of the fluid as would be ample for a slide or two if any member desired such. The Order, he contended, had not been properly advertised in the county, and he would meantime deprecate any prosecution until he was convinced that every farmer knew he was committing an offence under the Order by having a tuberculous animal in his possession. Under the present instructions two visits in most cases were all that were necessary. There were two sets of reports, and if there was a tuberculin test another set was necessary. They had nothing to do with cleansing or disinfecting, that was a matter for the sanitary authorities. They had nothing to do with the isolation of animals, they had no power to see that isolation was carried out. The County Clerk decided whether the animal was to be slaughtered.

Mr. BEGG said the Board intended the veterinary inspectors to serve the isolation notices, also the notices with regard to disinfection, and gave instructions as to how these should be carried out. The sanitary authorities had absolutely nothing to do with the Board of Agriculture's Order.

Mr. MORRISON said that, in the case of seizing an animal at a mart, the inspector was certainly supposed to serve the isolation notices. The owner would tell where the animal was to be removed to.

The PRESIDENT urged on inspectors adopting uniform methods in carrying out inspection, and in reporting cases.

Mr. BEGG, in replying to a question, said that in order to increase the amount of compensation payable by the Board, an inspector was entitled to deduct from the salvage recovered, the expenses of float and slaughtering.

Mr. CLARK asked if, in the event of a milk sample proving positive on a smear by microscopical examination, whether a guinea-pig should be inoculated with the sample in order to clinch matters.

Mr. BEGG said certainly not. If acid-fast bacilli were found in the smear from a milk sample drawn directly from the suspected quarter of the milk cow it could be relied on that the acid-fast bacilli are tubercle bacilli, and the need for biological experiment did not arise.

The PRESIDENT said that in Aberdeen he had full power. If he wished to seize an animal, one visit was sufficient. Certainly any emaciated cow below the value of £4 should be seized.

Mr. BEGG said the whole point was that veterinary inspectors should be given a free hand in the condemning of animals under the Order.

Mr. HOWIE said that every man would just have to use his discretion.

The PRESIDENT thanked Mr. Kerr for his paper, and Mr. Howie, in proposing a similar compliment to Mr.

Begg, referred to his high professional abilities and the unusual knowledge he possessed in connection with the administration of the Tuberculosis Order.

Mr. KERR read a short paper on "Veterinary Ethics," but owing to want of time the discussion was postponed until the meeting in August.

It was agreed that by the time next meeting was due, the International Veterinary Congress would have been held. Therefore those members who had been able to be present would give an account of the proceedings for the benefit of those who had been unable to get to London.

A hearty vote of thanks to the President for his conduct in the chair brought the business meeting to a close.

Mr. MARSHALL, in acknowledging, invited the members to assemble at the front of the College buildings for the purpose of being photographed, and said he would be very pleased if each member would accept a copy from him as a memento of the occasion.

[A reproduction of this photo will be issued with our next number].

THE DINNER.

At the conclusion of the business meeting, the members dined together in the Royal Hotel. Mr. Begg was also present. Mr. Marshall presided, and gave the loyal and patriotic toasts. Mr. W. Brown and Mr. Peddie, Dundee, replied for the Army and Territorials respectively.

PRESENTATION TO MR. HOWIE.

Mr. SKINNER handed over on behalf of the Society to Mr. Howie an illuminated address, veterinary instruments, and a set of books for his valuable services to the Society since its inception more than 20 years ago. He said it was almost 30 years ago since Mr. Howie and he sat at classes together, and his brilliant success as a student was still fresh in his (Mr. Skinner's) memory. It was almost 20 years since Mr. Howie aided very materially in founding the Society, and his wise and kindly counsel at the time he (Mr. Skinner) could not forget. During the existence of the Society Mr. Howie had rendered many valuable services to the institution in his capacity as member, President, and as Hon. Sec. In the latter capacity he excelled. (App.)

On behalf of the Society Mr. Howie undertook many long journeys at not a little inconvenience and entirely at his own expense, and he had done much in furthering the cause of those more concerned with the administration of the Contagious Diseases Act. To that section of the Society he had given valuable aid. At one time the Society showed signs of depression, but thanks to the tact and energy displayed by Mr. Howie at the crisis, a shipwreck was averted, and the Society stood now on as sound a basis as any other institution of its kind in this country. (Applause.) They were all deeply sensible of the gratitude which they owed to Mr. Howie, and they had decided to show their indebtedness in a practical way. Brilliant scholar, able veterinarian, a business man of splendid capacity, and above all a thorough gentleman in all his dealings, Mr. Howie had won in a marked way the respect and gratitude of them all, and the honour that was done to him at the hands of the Society was richly merited. (Applause.) Mr. Skinner concluded by handing the gifts to Mr. Howie, and hoped that the good wishes of the company would be fully realised. (Applause.)

[The presentation comprised:—Huish's Revelation Mouth Gag, A System of Veterinary Medicine (Hoare), Diseases of the Dog (Müller), Veterinary Pathology, 2 vols. (Friedberger and Fröhner), Regional Veterinary Surgery (Dollar), Neumann's Parasites (Macqueen), Veterinary Hygiene (Smith), Clinical Bacteriology and Vaccine Therapy (Scott), Surgical Diseases of Dog and Cat (Hobday), Walley's Meat Inspection (Stockman)].

Mr. Howie's health was drunk with enthusiasm, the company singing "For he's a jolly good fellow."

Mr. HOWIE, in acknowledging, said he was deeply touched by the kind words of Mr. Skinner, and he heartily thanked every one for their gifts as a mark of any little service he had rendered to the Society. All men were born with talents; any little he had lay in organisation. From all the officials and members of the Society he had always received the utmost courtesy and the most valuable assistance. These he thanked, and also those who accompanied him on deputation and other business. As he liked very much the work associated with the Secretaryship, they might count on him for a while yet. (Applause).

PRESENTATION TO MR. W. BROWN.

The PRESIDENT then handed to Mr. Brown, Lecturer in Veterinary Hygiene, Aberdeen University, a framed address and a set of books in recognition of services rendered to his professional brethren—lectures and demonstration at Marischel College. The President referred to Mr. Brown's brilliant career as a student, to his special training in France, to the practice of his profession in England and then in Aberdeenshire, and finally to his selection as lecturer in veterinary hygiene in Aberdeen University.

Mr. Brown's health was then drunk with musical honours.

[The gift of books comprised:—Special Pathology (Hutyra and Marek), Traité de Thérapie Chirurgical (in preparation), Parasitology of the Domesticated Animals (in French, by Neven Lemaire), Sisson's

Veterinary Anatomy, Veterinary Pathology (Friedberger and Fröhner), Diseases of Cattle, Sheep and Goats (Moussu), Veterinary Toxicology (Lander), Veterinary Hygiene (Smith), The Elements of Bacteriological Technique (Eyre), Practical Bacteriology (Besson)].

Mr. BROWN, in replying, said the gift was more than he could have ever hoped for. It was only two or three years ago he joined the Society, and he must say that he had received great benefit from it. If plenty of young men had got the opportunities which he had got he was sure they would have done much better than he did.

Mr. Brown gave a short account of the instruction he got at Paris and mentioned that he was to get a fully equipped research laboratory from the Scottish Board of Agriculture. He hoped members would consult him on any matter on which they thought he could be of service to them. (App).

Mr. BEGG gave "The North of Scotland Veterinary Society," and urged unity of action. He was delighted to see that in the north they had such a healthy and progressive Society.

Mr. CUMMING acknowledged the toast, and mentioned how frequent meetings and discussions on important matters bearing on the profession, would help them all.

Mr. SIEWRIGHT proposed "The Visitors," and Mr. Begg replied.

Mr. HOWIE gave the health of the newly elected President, and Mr. Marshall, who replied, thought they should at least meet three times in the year.

This concluded the proceedings.

GEORGE HOWIE, Hon. Sec.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Feb. 16 1914
NOTE.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

Foot-and-Mouth Disease.

The existence of foot-and-mouth disease was confirmed on Friday last, 13th inst., in the Birkenhead Irish Animals landing place amongst Irish animals which had been landed for the purpose of slaughter within the landing place, the Board of Agriculture and Fisheries made an Order prohibiting until further notice the landing in Great Britain of any cattle, sheep, goats, or swine from Ireland. The Order, however, permitted of the landing for the purpose of slaughter within the recognised landing places of animals already *en route* from Ireland.

The diseased animals in the Birkenhead Irish animals landing place were slaughtered, and all necessary precautions taken to prevent the disease from being conveyed by mediate contagion out of the landing place.

19th February.

The existence of foot-and-mouth disease has been confirmed to-day amongst cattle at Lowfell, near Gateshead, County Durham.

The usual precautions have been taken to prevent the spread of the disease, and an Order has been issued prohibiting the movement of animals in a large area surrounding the affected farm.

In the House of Commons, on Monday :

Mr. CRUMLEY (Nat. Fermanagh, South) asked the President of the Board of Agriculture whether now that no further outbreak of foot-and-mouth disease had occurred in Ireland for the past three weeks, he would remove the restrictions against the removal of fat and store cattle from Ireland to the markets in Great Britain.

Mr. RUNCIMAN : On Thursday evening last, the veterinary inspector in charge found very suspicious lesions in certain swine which were about to be slaughtered in the landing place at Birkenhead. An examination on Friday morning satisfied him as to his diagnosis of foot-and-mouth disease. Moreover, that same morning he found undoubted evidence of the disease in seven cattle forming part of a separate cargo. The swine had been landed from Waterford on Sunday, the 8th ; the cattle from Newry, on Tuesday, the 10th. Later that day disease was discovered in ten cattle forming part of a cargo landed from Dundalk, on Tuesday, the 10th. The vessel in which these cattle were carried returned to Ireland, and on Thursday, the 12th, landed swine from Dundalk, which showed lesions of the disease when examined alive on Friday evening. On Friday evening and Saturday morning disease was discovered in animals forming parts of four other shipments, namely, three arriving on the 10th from Belfast, Dublin, and Waterford, and one arriving on the 12th from Dublin. This cargo came on the same vessel as that which arrived on the 10th.

In these circumstances I have had no alternative but to prohibit the landing in Great Britain of animals from Ireland for the present ; and it may be well to state that under the most favourable circumstances there is no possibility of the trade being resumed for at the very least a fortnight from to-day.

Mr. C. BATHURST (U., Wilton) asked whether, in view of the alarm which this statement must cause to British stock-owners, the right hon. gentleman was satisfied that the inspection at the five Irish ports of embarkation was adequate.

Mr. McKENNA : The inspection at the five Irish ports has been better done during the last few months than it has ever been done before.

PARLIAMENTARY.

In the House of Commons on Friday, Feb. 13.

The following Bills were presented and ordered for second reading on various dates :

* * *

Col. WALKER (Lancs. Widnes, Opp.).—Bill to amend the Diseases of Animals Acts, 1894 to 1911, in respect of the exportation of horses.

Thursday, Feb. 18.

The following Bills were presented and read a first time :—

Mr. C. WASON (Orkney and Shetland, Min.).—A Bill to prohibit the vivisection of the higher animals.

Mr. SANDERSON (Westmorland, Appleby, Opp.).—A Bill to amend the Acts relating to the practice of veterinary surgery and medicine.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Feb. 13.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Lieut. F. B. Gresham to be Capt. Dated Jan. 10.

Maj. E. E. Martin, Army Veterinary Corps, has been appointed Commandant of the Army Veterinary School from April 1st next.

His Majesty the King held a Levée on Feb. 17th, at St. James' Palace. The following Noblemen and Gentlemen attended :—

* * *

Vet.-Capt. G. Rees-Mogg, F.R.C.V.S., 1st Life Guards.

Personal.

Among the arrivals by this week's mail was Mr. R. Paine, F.R.C.V.S., one of the most popular Government Veterinary Surgeons in the Province. When it was rumoured that he was going home on a holiday at the beginning of this year, a testimonial was organised for him ; but owing to his unexpectedly early departure, there was not sufficient time to get in completed. This, however, has now been done, and Mr. Paine was presented on his return with a handsome purse and an influentially signed testimonial, among the signatories being the following :—Right Hon. J. X. Merriman, Sir Thos. Smartt, the late Hon. J. W. Sauer, Col. W. E. M. Stanford, Mr. C. W. H. Kohler, Mr. J. C. Faure, Mr. H. Pickstone, Messrs. Starke Bros., Messrs. James Rawbone, M.P.C., H. Urtel, E. Lange, and the Hon. H. de Villiers.—*Cape Times*, Dec. 5.

OBITUARY

Mr. ALEX. W. M'KEAND, whose death was announced in our issue of Feb. 7, had not been in good health for some time. He was closely connected with the farming industry in the Machars district of Wigtownshire, and in addition to his private practice was veterinary inspector under the County Council for the parishes of Penninghame, Wigtown, Kirkcowan, Kirkinner, Mochrum.

A CORRECTION.

Dear Sir,

Please allow me to state that in your issue of Feb. 14th, my quotation referred to on page 535 is wrongly reported, and to prevent further misconception I beg to refer your readers to Section 44 (General Administrative Provisions) in the Handbook of Diseases of Animals Acts and Orders, etc.—Yours faithfully,
WM. CAUDWELL, M.R.C.V.S.
Chertsey, Feb. 17.

THE VETERINARY RECORD

No. 1338.

FEBRUARY 28, 1914.

VOL. XXVI.

THE USE OF SERUM AGAINST SWINE FEVER.

The Departmental Committee upon swine fever has issued a second interim report, which is solely concerned with the possibilities of serum and vaccination treatment. The report itself is short, but the inclusion of minutes of evidence and an appendix consisting of two official reports bring it up to nearly 40 pages. The whole is well worth reading, and the following is a brief summary of the main points.

The Committee have received information regarding the use of serum against swine fever in Holland, Hungary, and the United States. Special official enquiries have been conducted in Hungary and Holland by Lieut.-Colonel Sir Edward Clarke, Bart., Superintending Inspector of the Board of Agriculture, and by Messrs. Wragg and Broome, two of the Board's veterinary officers. The Committee have also considered two reports of independent enquiries by Mr. J. M. Harris, Vice-chairman of the Bacon Curers' Association of Great Britain and Ireland, and Mr. J. Higginson, M.R.C.V.S. In addition, Sir Edward Clarke and Messrs. Wragg, Harris, and Higginson have given evidence before the Committee.

The results are far from supporting the claims which have been advanced in some quarters for the serum treatment. The Committee conclude that "no satisfactory evidence was obtained to show that effective immunisation by artificial methods can safely be employed, except in conjunction with isolation and restriction on movement." They proceed—"In Holland serum has been supplied free, on demand, to veterinary surgeons during the past two years, and some 6000 inoculations appear to have been recorded. The method followed is to inoculate the pigs on infected premises with serum alone, relying on fortuitous infection to complete the process of active immunisation. This treatment is regarded as being still in the experimental stage. It is claimed that the use of serum reduces the number of deaths in the case of outbreaks. Evidence was given that in certain districts swine fever is very prevalent, but precise information is not available, as the disease is not scheduled, and outbreaks are not officially reported."

"In Hungary serum inoculation has been employed experimentally, in conjunction with isolation and restriction on movement, to a considerable extent. Experiments are now being commenced with simultaneous inoculation with serum and virus. In this country also it is claimed that the death rate on infected premises is reduced by the use of serum, but the statistics did not show any diminution of the prevalence of the disease."

"The official reports from the United States of America show that serum inoculation has been

employed much more extensively and for a longer period than in either Holland or Hungary, without effecting any reduction in the prevalence of the disease. The annual losses from swine fever have greatly increased, and appear to be still increasing. It is a matter of doubt whether the growing prevalence of swine fever may not be due to the spread of infection by inoculated pigs."

Finally, the Committee state their opinion that inoculation with serum alone affords too brief immunity to be of practical value; that every known method of vaccination, or simultaneous inoculation with serum and virus, exposes the inoculated animal to risk and renders it infective to others; that existing methods of inoculation do not promise assistance in the eradication of swine fever, though they might be serviceably employed in connection with a policy of control; and that further experiment is necessary with a view to finding a form of vaccination which will give active immunity to the inoculated animal without risk of further loss and dissemination of the disease. They conclude by suggesting that field experiments of serum and vaccination treatment on selected infected farms should be instituted in this country without altering the present restrictions on movement.

This report will not please the many pigowners who have been hoping that the advent of the serum here would sweep away the present harassing restrictions upon movement. But it seems clear that more has been claimed for the serum than its present apparent results justify. It cannot be called free from risk, and its efficacy has not yet been conclusively proved. The absence of scheduling and statistics in Holland almost nullifies the value of the experience there; and the American and Hungarian statistics are hardly encouraging. Nevertheless, further research may show that the serum has some value for this country or lead to some improved method; and we should be glad to see the suggested field experiments commenced. Sir Edward Clarke proposed setting aside a whole county for a compulsory field trial of serum *plus* restrictions, and named Wiltshire as a suitable one. This would be better than taking a small area; but it would require special legislation, which might not be easy to obtain. In Holland and Hungary alike the use of the serum is optional; and this helps to obscure the results.

Lastly, we should mention that Messrs. Wragg and Broome have been able to examine the various lesions of swine fever as it exists in Holland and Hungary, and find them identical with those seen in England. In view of the confusion which exists amongst the infectious diseases of pigs, this note by two such experienced observers is more than interesting.

RUPTURED UTERUS IN A SOW.

On February 15th, at 2.30 p.m., I was called to see a pedigree sow farrowing. On arrival I was told that she had passed one dead pig with difficulty at 12.30.

On examination I saw one hind leg protruding from the vulva, and upon inserting two fingers I found the other leg hitched to the roof of the vagina. This leg was quite easily released, and the pig, which was dead, delivered without trouble.

I then left, telling the man to sit with her, but allow her to remain undisturbed, saying I would call at 6.30 p.m.

Arriving at the appointed time, I was told she delivered another pig at 4.30, without apparent trouble, this pig being alive and strong.

I called again next morning, and the man told me she had been quiet all night, and had passed her cleansing, which I examined, noticing at the time that there was a large quantity, considering that only three pigs had been born. She had taken food and walked about, and except for a slight swelling of the vulva, which I ordered to be bathed, she appeared well.

On February 17th, at 8.15 p.m., the man called to say the sow had taken food at 5 p.m., walked to her bench, and died almost immediately.

On February 18th I made a post-mortem examination. On opening the abdomen, a large quantity of blood-tinged fluid escaped, and lying in contact with the intestines were three pigs without foetal membranes. Removing three, I noticed the intestines were very inflamed, but after carrying my incision further towards the sternum, I saw a fourth pig lying in contact with the right lobe of the liver and in a perpendicular position.

The uterus had a large hole on the under surface, and contained a very small portion of foetal membrane.

I consider this a peculiar case; firstly because nearly all the foetal membranes were passed on the night of the 15th, so that the four pigs must have been in the abdominal cavity at the time. Secondly, the sow had fed and walked about without showing distress on the 17th; and thirdly, on account of the position of the fourth pig.

V. PRIDE-JONES.

Bristol.

AGE OF CATTLE AFFECTED WITH TUBERCULOSIS AND SLAUGHTERED UNDER THE ORDER.

Out of 62 reported cases I have slaughtered 49 cattle up to date, the ages being as follows:—

Yearlings	3	Six years' old	14
Two years old	—	Seven " "	4
Three " "	3	Eight " "	6
Four " "	7	Nine " "	4
Five " "	6	Ten " "	2

Apparently the liability to the disease gradually increases towards middle age, and then slowly wanes.

I have made post-mortems of two cows aged 15 years, which I passed out of the order, and found them free.

ABSTRACTS FROM FOREIGN JOURNALS

THE PATHOGENY AND TREATMENT OF LAMINITIS.

Régnier publishes (*Revue Générale de Méd. Vét.*) this question. At the present time the ætiology and pathogeny of laminitis are still greatly disputed. In most cases the cause of the disease seems to be over-exertion, coupled with the excess of nutrition, but cases are also observed which must be reckoned as consequences either of parturition or of the method of feeding alone, or of an infectious disease.

Most authors favour the opinion that the disease consists essentially of a congestion and inflammation of the cutis vera of the foot. Saumur's school regard it as an osteitis of the third phalanx, and a third hypothesis classes it in the group of localised infections or toxi-infections.

The author reports two cases of laminitis in which the horses had not previously gone out of the stable, and had neither done work nor, at any previous time, shown an osteitic disease.

The first case was a colt which had been castrated six days before, and had since been very lightly fed. Great swelling around the castration wound, high fever, and an attack of laminitis upon all four feet, appeared simultaneously. Under the influence of appropriate treatment—bleeding, mustard plasters, and an injection of arecolin—the symptoms subsided, and three weeks afterwards the animal was cured.

The other case was a four-year-old stallion, which had been richly fed, and was suddenly attacked by subacute laminitis with very alarming general symptoms. The temperature was 105.6° F., while the pulse was 92, and the respirations 72 per minute. After an intravenous injection of tallarine and the administration of an electuary of quinine and theobromine, the fever went down. The laminitis itself was treated with injections of arecolin, and the horse was placed upon a milk diet. The laminitis gradually subsided, and the animal recovered completely.

The author ascribes the first case as a toxi-infectious influence proceeding from the castration wound. The other case, he thinks, had had its cause in a too rich nourishment, and had likewise taken a toxi-infectious course. He recommends that such a case should be dealt with, not by local treatment, but by an immediate general treatment with the object of eliminating the toxic materials from the organism. Injections of arecolin, and the administration of theobromine fulfil these requirements.—(*Berliner Tier. Woch.*)

MAMMARY BOTRYOMYCOSIS IN THE MARE.

Willy Plötner, a Berlin veterinarian, has published (*Monatsheft für Prakt. Tierheilkunde*) an article upon this condition, in which he enunciates the following views regarding treatment.

Early extirpation of the mammary gland is the best treatment for botryomycosis of the udder. Iodides are not advisable as agents for curative treatment, as the tumour, which is fibrous and not well supplied with blood vessels, is but little influenced by their internal administration. Iodide of potassium, however, may be used in small and recent botryomycotic tumours, and is also serviceable before and after the operation of extirpating the mammary gland. Before the operation it disperses the phlegmonous swelling surrounding the botryomycotic tumour, and thus facilitates surgical interference. Afterwards it encourages the absorption of post-operative œdemas and swellings.

The operation is very simple. First a cutaneous incision is made in such a manner as to isolate all the diseased portion of the skin. The tumour is then detached, and this is effected by working from the periphery towards the deep parts, and using blunt instruments as far as possible. During this dissection a cord as thick as a child's arm is encountered about the inguinal region. This structure is formed of dense tissue, and fixes the tumour to the inguinal region. It contains the external pudic artery and the efferent veins of the mammary gland, and should be divided with an emasculator or by torsion. (A Belgian critic recommends applying a hæmostatic ligature, as the external pudic artery is very well developed, especially in breeding mares of heavy draught race).

When the diseased mammary gland has been removed, the supra-mammary lymphatic glands corresponding to it are removed also. Finally, if the size of the operative wound permits its closure by suture, this is done. If not, the open wound is treated on ordinary antiseptic principles.

In any case, the extirpation should not be limited to the diseased tissue alone. Half or the whole of the udder should be removed, together with the corresponding lymphatic glands, according to whether one-half or the whole udder is the seat of botryomycotic lesions.—(*Annales de Méd. Vét.*)

THE MISUSE OF WATER IN VETERINARY SURGERY.

Fontaine discusses (*Revue Vét. Militaire*) this question, and, on the ground of his surgical experience and more than fifteen years' practice, he condemns the excessive use of water in surgery and in the treatment of wounds.

Injurious microbes are present in water everywhere, however pure it appears to be. Washing wounds, even with sterile water, disperses and sows the dangerous microbes, and so delays healing.

The author details his procedure in surgical operations. Instruments are sterilised by boiling, and placed dry in a dish which has been sterilised by a flame. The operator and his assistants first clean their nails while dry, and then wash their

hands and nails in hot water which has been boiled, dip them in a 2 per cent. sublimate solution, and allow them to become dry before the operation. If the field of operation is small, it is sterilised with tincture of iodine; if it is extensive, or the skin of the region is fine, a solution of one part of metallic iodine to twenty parts of chloroform is used. Dry aseptic gauze is used for allaying hæmorrhage, and for binding up the wound after operation.

The author also condemns the use of water in the treatment of wounds which are already infected. In the case of superficial wounds, he avoids all washing, and finding painting with tincture of iodine and subsequent dusting with an absorbent powder completely satisfactory. In deep sinuous wounds, his procedure is different. He permits these to be washed out with the object of removing foreign bodies, and then proceeds to apply what he calls a "half-dry dressing." This consists of a pad of wadding, which has been lightly saturated with a 1 per cent. sublimate solution, and is kept closely applied to the wound. It is changed daily or every two days, but no further washing out is practised. Any collected pus is simply wiped away with a pad of wadding soaked in sublimate solution, and the "half-dry dressing" is re-applied. In the later stages the wound is covered with a dry dressing in powder form, and healing is accomplished under a scab.

In the case of a contused wound in the neighbourhood of a joint, the author prefers to first paint with tincture of iodine, and then apply a blistering ointment.

The same principles are followed in the case of deeply penetrating wounds of the foot. The author omits the so-called "antiseptic foot baths," and uses only a "half-dry dressing" composed of a pad of gauze or wadding which has been lightly saturated with sublimate solution and then squeezed out. The wound is not washed out when this dressing is changed, the pus being merely wiped away with the wadding.—(*Berliner Tier. Woch.*) W. R. C.

NORTH OF SCOTLAND
VETERINARY MEDICAL SOCIETY.
[NATIONAL V.M.A. SCOTTISH BRANCH.]

GROUP AT THE COLLEGE OF AGRICULTURE,
ABERDEEN, JANUARY 21ST., 1914.

Front (left to right): Messrs. A. Sievwright, Tarland G. Howie, Alford, (Secretary); W. Marshall, Aberdeen (President); D. Cumming, Culter, (Vice-president); Hugh Begg, F.R.C.V.S., Lanarkshire.

Second Row: Messrs. W. Marsden, Banff; W. Anderson, Keith; J. McBryde, Strichen; Wm. Brown, Aberdeen University; W. Lornie, Hatton; W. Skinner, Oldmeldrum; J. Ironside, Cluny.

Third Row: Messrs. R. Drennan, Aberdeen; D. R. Crabb, Aberdour; H. F. McVean, Craigellachie; D. Clerk, Stonehaven.

Back: Messrs. Jas. Peddie, F.R.C.V.S., Dundee; D. Morrison, New Deer; W. H. Robson, Laurencekirk; A. Bell, Fraserburgh; A. Kerr, Ellon; A. Johnstone, Fyvie W. McPherson, Huntly.

**MIDLAND COUNTIES
VETERINARY MEDICAL ASSOCIATION.
(NATIONAL V.M.A.—NORTHERN BRANCH.)**

The annual meeting was held at the Grand Hotel, Birmingham, on Friday, Feb. 13th. Mr. J. Martin, Wellington, presided, and there were also present:—Messrs. J. Malcolm, E. O'Neill, L. C. Tipper, J. Young, S. M. Woodward, Birmingham; R. C. Trigger, Newcastle-under-Lyme; W. E. Ison, Atherstone; W. Yeomans, Smethwick; D. Forwell, Towcester; T. Chambers, Dudley; F. L. Gooch, Stamford; G. Wartnaby, Burton-on-Trent; F. H. Gibbings, Nottingham; H. S. Reynolds, Daventry; H. L. Pemberton, Bridgnorth; W. S. Carless, Worcester; A. Over, Rugby; P. Evershed, Nottingham; J. Whyte, Tenbury; C. J. Clifford, Shifnal; A. Renfrew, Broadway; T. Slipper, Sutton Coldfield; W. H. Brooke, Handsworth; H. Collett, West Bromwich; R. Murray, Rugeley; W. G. Thomson, Stafford; A. B. Forsyth, Cannock; J. J. Burchnall, Barrow-on-Soar; L. W. Heelis, Solihull; and the Hon. Sec., Mr. H. J. Dawes, of West Bromwich.

The visitors present included: Prof. Brayley Reynolds, Messrs. J. White, H. Connachie, W. H. Bagley, E. Bagley, Birmingham; F. B. O. Taylor, Stratford-on-Avon; F. E. Heath, Moseley; G. H. Locke, Manchester.

Apologies for unavoidable absence were received from the following: Messrs. J. H. Carter, J. Abson, E. Ringer, T. H. Hobson, F. V. Steward, F. W. Barling, John Blakeway; J. Martin, jun., J. Bainbridge, R. Hughes, Tudor Hughes, J. Clarkson, E. Hall, W. H. Brown, J. R. Carless, W. Grasby, J. A. Gold, and others.

The minutes of the previous meeting were read and confirmed.

Nominations. Mr. F. O. TAYLOR, of Stratford-on-Avon, was nominated by Mr. Gooch for membership of the Association.

Mr. R. P. PALMER, of Warwick, by Mr. H. S. Reynolds.

Mr. F. E. HEATH, of Moseley, Birmingham, by the Hon. Sec.

The names of these gentlemen will be submitted for election at the next meeting of the Association.

TREASURER'S STATEMENT.

The HON. TREAS. (Mr. Burchnall) presented the balance sheet. This showed that the subscriptions and entrance fees received during 1913 amounted to £55. There was an item of £3 14s. 6d., representing bank interest, and these two sums, with the balance of £184 6s. 8d. brought forward from the previous year, made up the total assets to £243 1s. 2d. The liabilities included the annual contribution of five guineas to the Victoria Veterinary Benevolent Fund, and a contribution of £15 to the International Veterinary Congress fund (this being the second instalment towards a promised donation of £50). Details of other expenditure were also furnished, and the balance to be carried forward to the new year was £181 7s. 2d. Mr. Burchnall explained the slight reduction in the sum carried forward by stating that the balance sheet contained an item of four guineas, delegates' expenses to the Royal Sanitary Institute Congress in 1912, which was not included in last year's accounts. He believed that this year they had touched high water mark in the matter of income.

The HON. SEC., in proposing that the accounts be passed, said they were the most satisfactory he had ever known in the history of the Association, and were evidence of the keen interest which Mr. Burchnall took in his work.

Mr. GOOCH seconded the motion which was carried.

THE HUNTING FUND.

The HON. SEC. read a circular he had received from the Committee appointed to raise a memorial to the late Mr. Wm. Hunting. He said he was sure they would all want to subscribe individually, but as an Association they would want to identify themselves still further with the movement. He need hardly remind them that Mr. Hunting was one of their oldest members and a past-president. He understood that Mr. Trigger wished to give notice of motion.

Mr. TRIGGER said it was his intention at the next meeting of the Association to move that a sum of not less than ten guineas be subscribed by the Association to the Hunting Memorial Fund. He requested the Hon. Sec. to accept this as a formal notice of motion and to include it in the agenda for the next meeting, according to rule.

REPORT OF THE COUNCIL.

The HON. SEC. presented the report of the meeting of the Council of the Association held immediately prior to this general meeting:—

The Council have recommendations to make with regard to the appointment of officers for the ensuing year, and regret very much that Mr. Trigger, the senior Vice-President, cannot see his way to succeed Mr. Martin, owing to numerous other calls upon his time, both professional and public. The Council have persuaded Mr. Malcolm to accept office, and in view of the visit of the International Veterinary Congress to London this year, and the importance of having an influential and experienced head of our Association at such a time, they confidently expect Mr. Malcolm's unanimous election.

Mr. R. H. Over, of Rugby, is recommended as senior Vice-President, and Mr. H. S. Reynolds, of Daventry, is recommended as junior Vice-President in due course. Mr. Martin, the retiring President, becomes the third Vice-President *ex officio*.

Other recommendations to office are as follows: Hon. Sec.: Mr. H. J. Dawes; Hon. Treas.: Mr. J. J. Burchnall; Auditors: Messrs. W. S. Carless and R. C. Trigger.

Out of consideration for Mr. Malcolm, it is recommended that the next quarterly meeting be held at Birmingham. Mr. F. L. Gooch has invited the Association to hold their August meeting at Stamford, with the promise of a successful ladies' day, and this will be considered by the Council at their next meeting.

Mr. Malcolm has undertaken to communicate with Prof. Mettam with a view to his reading a paper at the next meeting.

It is recommended that to succeed Messrs. Wartnaby and R. Over who retire from the Council this year, Messrs. W. H. Brooke and T. Slipper be elected.

On the motion of Mr. Tipper, seconded by Mr. Gibbings, the report of the Council was received.

Resignations. The resignations from the Association of Mr. W. G. Burndred, Hanley, and Mr. Norman Thompson, formerly of Derby and now of London, were accepted with regret.

ELECTION OF OFFICERS.

The HON. SEC., in moving that Mr. John Malcolm be elected President of the Association during the coming year, said that in view of the important happenings in the veterinary world this summer they wanted someone to preside over them who would command both the confidence and esteem of all the members. He thought they would agree with him that Mr. Malcolm was that man above all others. He was held in high repute both inside and outside the profession, and the amount of work he had done for the Association, both as an ex-secretary and an ex-president, entitled him to their last-

ing gratitude. If, as was the case this year, the Association had it in its power to confer any special honour on one of its members, Mr. Malcolm was the one most deserving of it.

Mr. TRIGGER said he had never seconded a resolution with greater pleasure than this. Mr. Malcolm would make them an ideal president at a time like this, for he was a man of high attainments and would most worthily represent the Association at the International Veterinary Congress.

The resolution was carried by acclamation, and Mr. Malcolm, in accepting the office, said he regarded the honour as another manifestation of the goodwill which the Association had always borne him. He took the position with considerable reluctance, but he was satisfied that he would have at his command the sympathy and support of every member during a busy year.

Vice-Presidents. Mr. R. H. OVER and Mr. H. S. REYNOLDS. Mr. MARTIN would be a Vice-president next year *ex-officio*. Mr. Gooch proposed and Mr. Carless seconded, and carried.

Hon. Treasurer. Mr. J. J. BURCHNALL was unanimously re-elected on the motion of the Hon. Sec., seconded by Mr. Tipper.

Auditors. Messrs. CARLESS and TRIGGER.

Hon. Secretary. Mr. MALCOLM said he would like to have the opportunity of proposing the re-election of Mr. Dawes. Mr. Dawes, he said, was hon. sec. during his first presidency of the Association twenty years ago, and he would be very sorry not to have the benefit of his services again. This was seconded by Mr. A. Over and unanimously carried.

The Council were re-appointed with the substitution of Messrs. Brooke and Slipper for Messrs. Wartnaby and R. H. Over.

VOTES OF THANKS.

Mr. GOOCH proposed a vote of thanks to the retiring officers for their services during the past year, and said it was a matter for congratulation that during the past twelve months the Association had enjoyed a greater measure of prosperity than ever before. This was seconded by Mr. Chambers, and heartily agreed to.

The PRESIDENT briefly acknowledged the compliment, remarking that although the membership of the Association continued to grow, there were still many eligible men outside their ranks who ought to join.

DEMONSTRATION BY PROF. BRAYLEY REYNOLDS.

Prof. E. Brayley Reynolds (London) gave two demonstrations of canine surgery, which were followed with much interest, the only regret being that there was no time afterwards for discussion. The first operation was upon a toy Pomeranian bitch which was suffering from double inguinal hernia. The second was ovario-hysterectomy on a fox terrier.

TUBERCULOSIS IN BOWEL OF A CAT.

Prof. REYNOLDS brought with him to the meeting part of the abdominal viscera of a cat. It consisted of part of the ileum, the cæcum, and part of the colon, along with the adjacent mesenteric lymphatic glands. These were greatly enlarged, and on microscopical examination had been found to be very rich in tubercle bacilli. Prof. Reynolds remarked that he thought it was a condition that was more common than was generally supposed, this case being about the tenth that he had seen during the past two months. The condition, when in the advanced stage as this case was, was easily ascertained by palpation through the abdominal wall.

THE ANNUAL DINNER.

The annual dinner of the Association was held in the evening, Mr. Martin again presiding. The toast of "The King" was first honoured.

Mr. F. L. GOOCH then gave "The Royal College of Veterinary Surgeons." He referred to the honour which the profession would enjoy this year of receiving a visit from the International Veterinary Congress, and said they looked to the Royal College to do what was necessary in the matter. Of course, those in authority could do nothing without the support of the general body of practitioners, and he hoped they would see to it that nothing was wanting on their part to enable the Royal College to entertain the delegates in a fitting manner. It was a feather in the cap of the profession to have the Congress in this country, and as they had no Government subsidy to fall back upon, as was the case in other countries, the duty of giving their veterinary colleagues from abroad a proper welcome fell upon veterinary surgeons themselves. He felt sure everything possible will be done to uphold the credit and dignity of the profession in that respect. He regretted that the general finances of the College were not all they should be, but when the new Bill was passed into law anxieties of that kind would be ended.

Mr. T. CHAMBERS was called upon to acknowledge the toast, and he claimed to be voicing the opinion of all who had the veterinary profession at heart when he said they all hoped the Bill would soon become law.

Prof. REYNOLDS proposed "The Midland Counties Veterinary Medical Association." This, he said, was his first visit to the Midland Association, although he was a Midland man himself, and he was pleased to find from his own observation that it was the flourishing and successful Association it was always represented to be. He thought it was the duty of every veterinary surgeon to join a local association as soon as he left College, or at any rate as soon as he settled down in practice. If they had done so more generally in the past there would have been less need for the appointment of outside inspectors, because the work could have been done through the local associations. The main object of these associations was to promote professional knowledge, and those men who were better endowed than others owed it as a duty to their less favoured colleagues to impart that knowledge whenever they had the chance. It was equally a duty owing to the client for every veterinary surgeon to attend the meetings of his association, for there was scarcely a meeting at which there was not something to be learnt. That, at least, was his own experience. He congratulated the Midland Association upon being so well officered, and referred specially to the work of the Hon. Sec. They were happy, too, in their choice of Presidents, and to the list of distinguished men who had already filled that office he was pleased to see the name of Mr. Martin added.

The PRESIDENT, replying, agreed with the proposer of the toast as to the need for every veterinary surgeon to identify himself with his fellow practitioners in the way which membership of a local association afforded. He had found during the last twelve months that the office of president was not exactly a sinecure, but thanks to the energy and zeal of their Hon. Sec. the work was performed smoothly and pleasantly. Incidentally, he thanked Professor Reynolds for his attendance that day and for the demonstrations in canine surgery which he had given. He was sorry time would not permit of the meeting being resumed when the operations were concluded, but he was sure they had all enjoyed seeing Prof. Reynolds at work more than listening to speeches. For his own part he had certainly learnt more.

The HON. SEC. proposed the health of "The Visitors," and said if there was one thing more than another upon which the Midland Association prided itself it was in the warmth of its welcome to non-members.

Mr. LOCKE responded, and after acknowledging the great hospitality that had been shown to him, extended

an invitation to any member of the Midland Association to visit the Lancashire Association whenever it was in their power to do so.

The HON. SEC. said there was one other toast which ought to be honoured, and that was the health of Prof. Reynolds, who had proved himself a most skilful operator, and delighted them all that day with his work. He, personally, was very grateful to him for coming amongst them, and he would like to endorse what Prof. Reynolds had said about the desirability of every veterinary surgeon making a point of belonging to some association. It was only by united action that they could safeguard the interests of the profession, and the stronger an association was the better it must be for its members.

Prof. REYNOLDS briefly replied, and the gathering afterwards dispersed.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

LINCOLNSHIRE AND DISTRICT VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—SOUTHERN BRANCH].

The annual meeting was held at the George Hotel, Grantham, on Feb. 18. Mr. C. W. Townsend, F.R.C.V.S., presided, and also present were Mr. T. Holmes, Burne (Vice-President), Messrs. H. A. Allott, Upwell; D. Cooper, Saxilby; F. L. Gooch, Stamford; C. Hartley, Junr., Lincoln; T. Hicks, Sleaford, Hon. Sec.; A. Johns, Kimbolton; A. D. Lalor, Sleaford; W. W. Lang, Ulceby; G. Lockwood, Peterborough; W. Marshall, Horncastle; T. A. Rudkin, Grantham; H. C. Taylor, Caistor; Mr. Gresham, Newark, being a visitor.

Messages apologising for absence were received from Messrs. C. Hartley, Senr., E. Wardrop, W. W. Grasby, H. H. Truman, T. B. Bindloss, L. L. Leach, H. Leach, G. B. Dickinson, and A. R. Routledge.

The Minutes were duly signed.

DEATH OF MR. W. HUNTING.

The PRESIDENT said that since their last meeting they had lost one of the most respected and honoured members of the profession; he referred to Mr. Hunting. As an honorary member of the District he was an esteemed friend, as he was throughout the profession generally. He knew it would be the wish of the members to express their deep sympathy with the relatives, and he moved that a resolution of condolence should be sent. He added that Mr. Hunting had always been ready to assist them by reading a paper or otherwise, and only last July he said he would come down whenever they asked him. It was a matter of great regret that they would not have him with them again.

Mr. F. L. GOOCH, in seconding, said that if Mr. Hunting excelled in any quality it was in his desire to help on young practitioners. His name would be handed down to future generations if only for the work he did in the suppression of glanders. He loved his profession, and the members of it, and he was never so happy as when spending money on it. They could not do better than subscribe to the memorial that was being raised for him.

The resolution was carried in silence, all standing.

COUNTY COUNCIL FEES.

The HON. SEC. said he had written to the Clerk of the Holland County Council with regard to their fees under the Tuberculosis Order, and the County Council had agreed to their suggestions, except that they only allowed 6d. per mile travelling expenses one way.

Mr. LALOR: In the Kesteven Division they give 1/- per mile both ways.

A Member: And in the Lindsey Division.

Mr. LALOR: I had a letter from Mr. Gane, of Boston (Clerk to the County Council) saying they were going to adjust it.

The HON. SEC. said the Hon. F. McLaren, the member for the Spalding Division, had been written to, and had promised his services in the matter.

In the course of discussion, the President expressed the opinion that as medical practitioners they were entitled to rebate under the petrol tax.

Mr. GOOCH also pointed out that they could claim exemption, as in the medical profession, from juries, and several members said they had successfully done so.

THE NATIONAL.

The HON. SEC. reported that he had paid £1 11s. to the National Veterinary Association, 1s. for every paid-up member.

FINANCIAL STATEMENT.

Mr. HICKS presented the balance sheet, which showed the income to have been £29 12s., the balance at the bank at the end of the financial year £38 2s. 3d.

The PRESIDENT: I think we can congratulate Mr. Hicks that the balance at the Bank has increased from last year.

The financial statement was adopted.

The HON. SEC. reported a number of outstanding subscriptions. Some members who had not paid never came to the meetings.

Mr. GOOCH pointed out that Rule 7 decreed that members who had not paid their subscriptions for four years should be struck off the roll. He moved that registered letters be sent to members in arrear calling their attention to this rule, and stating that it would be put into effect if they had not paid at the next meeting.

Mr. HOLMES seconded, and this was agreed to.

ELECTION OF OFFICERS.

Mr. TOWNSEND (the retiring President) remarked that the International Congress would be held in the ensuing year, and it was necessary that as President they should have someone to represent them to the credit of the Society. He should like to propose as President the name of Mr. Gooch, who had served the Society well, and was secretary for seven years.

Mr. GOOCH asked to be excused, as he should be at the Congress, and had already filled the presidential chair.

Mr. T. HICKS said he should like to propose the re-election of Mr. Townsend, for he had already taken part in the preliminary arrangements for the Conference.

Mr. C. HARTLEY, jun., heartily seconded, and it was carried unanimously.

Mr. TOWNSEND said he considered it a very great honour. It had always given him much pleasure to do anything for the Society. It had been a very pleasant year, and he thought they could say a fairly successful one, there having been good attendances at the meetings. He thanked them all for the support they had given him, and especially the Secretary, who had quite fulfilled his anticipation when proposing him last year.

Vice-Presidents. Messrs. W. W. GRASBY, T. HOLMES and H. H. TRUMAN were re-appointed, on the motion of Mr. Gooch, seconded by Mr. Lalor.

Hon. Sec. The President proposed the re-election of Mr. HICKS. He had great pleasure in asking Mr. Hicks to act again. Mr. Gooch seconded, and it was agreed.

Mr. HICKS, in returning thanks, said he could not undertake the duties but for his wife, and she said she was willing to take her part in the work. (Applause).

THE INTERNATIONAL CONGRESS FUND.

Mr. GOOCH said they had 41 members, and only 21 had promised subscriptions. The amount promised was

was 76 guineas, and the amount paid 51 guineas, but he expected to get the 25 guineas outstanding. He thought that was fairly good for a small Society, especially as it was stated at the last Council meeting that out of 4000 members only 700 had subscribed. The sum of £3,800 had been promised in all, but only £2,700 had been paid into the bank. The minimum cost of the Conference was placed at £4,000, but Mr. Garnett had told him that would not be sufficient. He should be pleased if members who had not subscribed would write to him or Mr. Garnett to say what they were willing to give. As they had a balance of £38 at the bank, he proposed that, as a society, they should give a donation of 5 guineas to the Fund.

Mr. Lockwood seconded, remarking that it was essential that they should make the International Congress in England a success, and it would be a slight on the profession if they did not entertain the foreign delegates in the same way as they had entertained them.

The PRESIDENT supported the suggestion, and it was agreed to.

Mr. GOOCH said that would make 81 guineas, and he hoped to make it up to 100 guineas. The following is the list paid or promised to date:—Messrs. T. B. Bindloss, 3 guineas; F. L. Gooch, 9 guineas; W. W. Grasby, 3 guineas; C. Hartley & Son, 10 guineas; T. Holmes, 3 guineas; T. Hicks, 2 guineas; A. Johns, 3 guineas; R. W. Knowles, 3 guineas; A. D. Lalor, 3 guineas; A. Lennox, 3 guineas; G. Lockwood, 3 guineas; J. Mackinder, 3 guineas; H. H. Nichols, 3 guineas; R. A. Routledge, 3 guineas; T. A. Rudkin, 3 guineas; F. H. Sugden, 3 guineas; H. C. Taylor, 1 guinea; C. W. Townsend, 3 guineas; H. H. Truman, 5 guineas; H. Westgate, 4 guineas; G. T. Willows, 3 guineas; the Lincolnshire V.M.A., 5 guineas.

SPECIMENS.

Mr. ROUTLEDGE and Mr. RUDKIN exhibited curious morbid specimens, and Mr. GEO. LOCKWOOD, of Peterborough, a cleverly devised cat box for security in operations.

SOME SURGICAL OPERATIONS ON THE DOG.

By Prof. E. BRAYLEY REYNOLDS, R.V.C., London.

Mr. President and Gentlemen,—I had expected that all or the greater part of the time at our disposal would have been occupied in demonstrating various operations before you. Unfortunately, however, operations upon the dog that are likely to provide suitable and interesting demonstrations are rather limited in number, and due to a somewhat usual perversity of fate, we have not been able to obtain the necessary subjects. I propose, therefore, to endeavour to fill up the spare time in making a few general remarks and in giving a more or less detailed description of one operation that I had hoped to perform before you to-day.

It is perhaps needless for me to remind you of the much more important place the treatment, both surgical and medical, of dogs takes in the ordinary routine of present day town and also country practices, than it did only a few years back. It would be mere plagiarism on my part to repeat the only too often made remark that as the introduction of motor traction has caused a falling off in equine practice, it is incumbent on veterinary surgeons to turn to canine work in order to keep the ledger returns up to the normal. Important as this financial side of the question is—and only those who have taken up this class of work know how successful it is in supplying the deficiency—I think there is another aspect which is equally important, and this is that owners now expect very much more from veterinary surgeons in connection with the treatment of dogs. Financial returns may be affected from this point of

view also. For some people may argue, rightly or wrongly, that if one cannot treat dogs successfully one cannot treat horses successfully. It is quite possible that the stable may be entered—or left, through the kennel, or perhaps even through the lady's boudoir. Further, it is this sort of work that creates more and more interest the more one does of it. In the majority of cases the value that is attached to the patient is a sentimental one, and not a commercial one, as is the case in most of the other animals. The work is usually of a more congenial character; it is cleaner and lighter, advice and orders are more faithfully carried out, and one is not bothered with such remarks as, Is it worth it? When can I get him to work? Do you think it necessary to see him again? etc. The surgical side of the work, and that is the one that more closely concerns us to-day, is perhaps the more interesting. From the general environment of the animal, and the size of its body, one can nearly approach human surgery. Certain it is that some operations can be successfully performed and others attempted with fair chances of success, which on the larger animals would be quite impossible.

I have several times heard the remark that operations are all very well for those who have a proper operating table, instruments, and plenty of help, but that the majority of practitioners are not so fortunate, and so cannot attempt them with the same hope of success. While admitting that is the case in a few of the more serious operations, when surroundings and particular instruments are more or less necessary, I do not think that they are in any way essential for the great majority of operations. A table on which one can fix the animal is a necessity. An ordinary deal kitchen table answers quite well, and is not expensive. The top should receive several coats of enamel to prevent absorption of fluids, etc., thus enabling it to be kept clean. A set of hobbles and sliding cords which can be fixed to clamps on the edge of the table or to hooks screwed into the sides or legs will make it complete. The benefit derived from the possession of such a table, even for performing very minor operations on the dog and cat, when an anæsthetic is not necessary, far outweighs the small initial outlay. No matter how much help one has, an animal cannot be held by hand with the same comfort to the operator as when fixed on a table. As I mentioned before, it is only for very special operations that special instruments are required. Very much can be done with the instruments that are in the possession of every veterinary surgeon.

What does appear to be a serious handicap to many veterinary surgeons is obtaining help, either for the administration of the anæsthetic, or perhaps actually to give a hand in performing the operation itself. We are not so fortunate as our medical brethren in this respect, one reason being that we are usually not quite such close neighbours, another that we are not so much inclined to ask one another's assistance, and I might suggest perhaps that in many cases the doctors do it only by compulsion of the law. Those veterinarians who have partners or assistants are not thus handicapped. To those who have not, I would suggest that they should train some member of their establishment in the administration of anæsthetics. I do not propose to go into details on the question of antiseptic or aseptic surgery and the question of anæsthetics. Details of them are already known to you, so it is unnecessary to occupy time in discussing them now.

As regards the adoption of antiseptic or aseptic methods in surgery, in some cases it is, of course, essential to adopt the former method. But in performing operations which involve surgical interference on healthy tissue only (the word "healthy" used in connection with the condition of the cellular elements of the tissues), I think the aseptic method is preferable, and gives better results. Antiseptics of sufficient

strength to have a harmful effect upon organisms must have such an effect upon healthy tissue cells that healing will be rather retarded than hastened. Again, one may be inclined to rely too much upon the services of the antiseptic, whereas in the adoption of aseptic methods one realises that success can be obtained only by scrupulous attention to detail. It is perhaps thought by some that these details are so many and exacting that they cannot be obtained amidst ordinary surroundings. I would remark in connection with this that it is not the multiplicity of the precautions one *might* take, but the thoroughness of the precautions one *must* take that is essential to success by this method. One must get fixed in one's mind that everything used in connection with the operation must be sterilised, and when once sterilised must not be allowed to come in contact with anything unsterilised. After a short time of strictly adhering to these precautions one finds it easy to observe them. I think I cannot do better than quote the following passage from a paper read by Prof. Woodruff before the National Veterinary Association meeting held in Manchester in 1912.

Dealing with this subject, he says:—"There is little need to say how essential this requirement is. All the triumphs of modern surgery are due to the antiseptic method devised by Lister, and modified and developed by succeeding surgeons. At the present time in human surgery the antiseptic era has almost given way to the aseptic, with very great advantage. In veterinary surgery the aseptic method is less convenient and demands a more rigid routine than the antiseptic. Nowhere is the saying "Cleanliness is next to Godliness" so well illustrated as in the operating theatre. The ritual to be observed in securing asepsis is as exacting as the ritual in the high cathedral. There is need to emphasise this, for it may safely be said that no operator not constantly using and practising the aseptic ritual can hope to attain it. How often has one seen the most painstaking and elaborate preparations for an aseptic operation completely nullified by a certain disposal of an instrument—knife, forceps, or needle and silk—on a dirty table or on the unprepared skin, or some other equally septic place, when some emergency like the section of an artery arose in the course of the operation. In asepsis, as in every other ritual, only the trained priests can minister at the altar."

The introduction of the use of Tr. iodine has somewhat simplified the preparation of the operation area.

In connection with anaesthetics, I would simply remind you of the use of morphia as an anaesthetic in the dog. Many operations can be performed while the animal is under the effect of this drug alone, a point that is important to those who are single-handed. One may employ a local anaesthetic in conjunction with it, or if necessary, chloroform, and in this latter case only a small quantity of the drug is necessary. The excitement stage, often so noticeable when this drug is used alone, is absent. Another benefit to be derived from the use of morphia is that owing to its prolonged action the animal remains under its influence for some hours. The quietude so obtained may have a markedly beneficial effect on an operation wound.

INGUINAL HERNIA IN THE BITCH.

I propose to give you now some observations on the operation for inguinal hernia in the bitch; text books are somewhat meagre in their details on this subject.

Occurrence. The condition is met with in bitches of all ages, irrespective of whether the bitch is a maiden or not. It is sometimes noticed to occur a few days after mating. On the other hand, bitches suffering from bad inguinal hernia may become pregnant, and provided a gravid horn of uterus is not present in the hernia, may give birth to puppies quite normally.

Causes. Accidents causing sudden pressure or tension on the abdominal wall may be a cause. I might note that in hernia from this cause the hernial sac is often absent, actual rupture of the peritoneum having taken place, allowing the escape of some of the abdominal organs down the inguinal canal. Excessive coughing set up by, say, chronic bronchitis, may also bring about the condition. It is probable that an anatomical arrangement in this region in the bitch may be a predisposing factor. The round ligament of the uterus, which is the homologue of the gubernaculum testis of the male, arises from the extreme end of the uterine horn in the region of the fallopian tube, passes down through the inguinal canal and becomes lost towards the perineal region. A larger or smaller amount of adipose tissue accompanies it in its passage through the inguinal canal and tends to keep this more or less patent.

Diagnosis. The hernia appears as a flaccid enlargement in the inguinal region varying in size from a walnut to a coconut. It may be recent in occurrence or may have been in existence for many months or even years without having caused any harmful effects. Generally there is but one side affected and that the left one. Probably there is some analogy between this peculiarity and the fact that the left testicle in the majority of males of most species is lower than the right one. Occasionally a hernia is present on both sides.

It is necessary to distinguish hernia from other abnormal enlargements in this region. Such enlargement may be a localised chronic mastitis, an inflamed lymphatic gland, or a neoplasm in connection with some of the tissues in this region. It is also necessary to distinguish it from the so-called false inguinal hernia, a term used to describe a condition caused by an increase in the amount of fat normally present in connection with the round ligament of the uterus as it emerges from the inguinal canal. Careful palpation of the parts while the animal is laid on its back will enable one to make a definite diagnosis. Points that may assist in this connection are (1) the consistence of a hernia is as a rule more elastic and flaccid than that of other enlargements in this region. If the hernia is a strangulated one the swelling may be more tense and there will be pain on pressure, and other symptoms will be present. (2) It is possible on palpation to trace the hernia contents into the inguinal canal. Further, one may be able to make out the nature of the contents, which consist most commonly of one or more horns of the uterus, sometimes intestine, bladder or some other abdominal organ. (3) The smaller hernias are usually reducible, and many of the larger also if one exerts patience and perseverance. This fact will help to differentiate true from false hernia. A false hernia is not reducible, whereas a true hernia of the size of the largest false one is reducible.

Operation. Except in the case of a strangulated hernia, where immediate operation is necessary, the patient should have been prepared by receiving a dose of castor oil and the part shaved and washed the day before operating. A general anaesthetic is necessary; morphia followed by chloroform will answer admirably. The seat of operation is painted with Tr. iodine, and, of course, all instruments, swabs and trays sterilised, and the operator's hands thoroughly cleansed and disinfected. The animal is fixed in a dorsal position on the operating table.

If at all possible reduction should be first attempted. If this is successful a very much smaller external incision will suffice. An incision about 1½ inches long is made directly superior to the external inguinal ring, parallel to the line of junction of the thigh with the body. The skin, the dartoid tissue, and any fascia present should be incised down to the herniated peritoneal sac, care being taken not to puncture the latter.

It will be found that the making of the incision will be facilitated if complete reduction has not been carried out, or if part of the hernial contents be allowed to return into the sac after reduction has been found to be possible. The hernial sac thus laid bare can then be withdrawn through the incision, practically no dissection, blunt or otherwise, being necessary. There is consequently no bruising of the tissues, and, since no vessels pass from the sac to the surrounding tissues, there is no hæmorrhage. These two facts have considerable bearing on the subsequent healing of the wound.

If the hernia is not reducible a somewhat larger incision is made in a similar manner. The incision need be only very little longer, since the hernia contents not being in the form of a solid mass will pass through a comparatively small opening. It is beneficial to keep this external incision as small as possible. The sac and its contents having been withdrawn reduction is again attempted and, provided there is present neither any adhesion of the contents nor a gravid horn of the uterus, reduction is almost sure to be possible, without having to resort to the enlarging of the inguinal ring. The end of the sac is grasped with a pair of forceps—ordinary artery forceps answer well—then while the contents of the sac are subjected to digital manipulation towards the region of the inguinal canal, the forceps are gently turned, twisting up the sac and exerting a gentle enveloping pressure. After complete reduction the sac is ligatured close up to the inguinal ring, care being taken not to include a large vein which passes up the median side of the inguinal canal. The sac is then taken off below the ligature. I might here remark that when hernia is present the inguinal canal is practically non-existent; the internal and external inguinal rings being almost directly superimposed to one another. For this reason, and especially when the rings have become much dilated due to the hernia, it is advisable to insert two or three sutures as a support. The sutures should pass from Poupart's ligament on the outer side to the combined aponeuroses of the external oblique, the internal oblique, and the transverse abdominal muscles on the inner side of the ring. Care must be taken not to injure any vessels which are adjacent to these parts or serious hæmorrhage may result, with which it is difficult to deal.

In cases where there are adhesions it may be necessary to open the sac before reduction can be effected. This is also necessary if a pregnant horn be present; the whole horn containing the fetus can then be removed, or, if the uterus and fetus are healthy, and it is desired to retain the bitch for breeding purposes, the horn may be opened and the fetus removed. The wound in the uterine wall, if the latter method has been adopted, is carefully sutured with Lembert's sutures and the organ returned into the abdominal cavity. The sac and inguinal ring are then dealt with in a manner similar to that described above. The cavity previously filled by the hernia is then mopped out and any blood clot removed. The edges of the skin wound are brought together by closely placed interrupted fine silk, or silkworm gut sutures.

There is one point in connection with this of which strict observance is necessary, as I consider it has a great influence upon the early healing of the wound. Owing to the position in which the dog is usually fixed, the skin is dragged up from the abdominal wall, from which it has been separated over a large area by the hernia, and air is easily included in this space when suturing the external wound. Any air so included will, before its dispersion, keep the opposing surfaces apart, prevent early adhesion and encourage oozing into the space from small severed bloodvessels or lymphatics. Subsequent swelling is much greater. Care should be taken to exclude any air. To do this the last two sutures should be inserted, but not tied, the hind leg on

the affected side should then be released, flexed, and the thigh pressed lightly to the abdominal wall. The air can then be easily expelled by slight manipulation of the surrounding parts, and the remaining sutures tied. The wound should be painted with Tr. iodine, and a pad of gauze and cotton wool applied and held in position by means of a many-tailed bandage.

Mr. GOOCH proposed a hearty vote of thanks to Prof. Reynolds for his paper and the operation he had performed, and said they were greatly indebted to the gentlemen from the College who came down from time to time.

The PRESIDENT, in seconding, said it was very good of Prof. Reynolds to come down, and the subject he had chosen was one that he was sure they would all turn their attention to.

The motion was carried unanimously.

New Member. Mr. GRESHAM, of Newark, was nominated as a member of the Association, by Mr. Rudkin, seconded by Mr. Lalor.

The business proceedings concluded, an adjournment was made for high tea.

T. HICKS, Hon. Sec.

REPORT OF THE DIRECTOR OF ABATTOIR AND LIVE STOCK MARKET, JOHANNESBURG, FOR THE PERIOD 1ST JULY, 1912, TO 30TH JUNE, 1913. [ABSTRACT].

Shortly after the opening of the stockyards and abattoir at Johannesburg in 1910 we printed a description of them, with several illustrations, [Nov. 5th, 1910] to-day we are able to record the progress and the undeniable success of the scheme initiated and carried through under the direction of a veterinary surgeon—Lt. Col. James Irvine Smith, M.R.C.V.S., (Commanding Transvaal Veterinary Corps). His persistence has overcome all opposition (including that of Medical Officers of Health) and has created an establishment which has, perhaps, no superior in Europe.

Twelve years ago the Johannesburg abattoir consisted of a few gallows in the *open veldt*, and under no control or inspection. The meat was killed under the most revolting sanitary conditions. Colonel Smith knew his mind, and how to arrive at what was necessary in spite of obstruction. Very much of the success depended upon finding water—and he found it. The report shows that one of the boreholes shows signs of failing, and the estimated cost of the work to replace it.

He was the first to show that unskilled white labour could be profitably employed, and in this matter has worked a revolution which can only be appreciated by those familiar with South African conditions.

The ramifications of his work are numerous, quite a new order of affairs is springing up in consequence of his attacks on the railway authorities for their carelessness in transporting animals. He has killed the expensive frozen meat trade, carried on by the Coast with Johannesburg, by producing all that was required in the form of fresh meat, and he now projects the exportation of meat.

Col. Smith graduated from the Glasgow College in 1898. It is gratifying that his remarkable personality has found acceptance in a new country instead of being left to lie unrecognised and neglected in this.

Operations during the period under review reveal a sound financial position, a further increase in trade, producers and consumers brought into closer touch with each other, and the adoption of further safeguards with a view to securing a high standard of purity in the meat supplies.

The turnover in the live stock market was approxi-

mately £3,660,728, an increase of £517,611 on the previous year.

The number of animals passing through the live stock market was 1,051,951, an increase of 75,817.

The number of animals slaughtered in the abattoir was 476,046, an increase of 22,310.

The total amount of meat seized and condemned was 430 tons, an increase of 146½ tons.

FINANCIAL POSITION.

The gross earning was £38,218, an increase of £3,079; the working expenditure was £22,277, an increase on the previous year of £572. The result was a gross surplus of £15,941, as against £13,850 in 1911-12. The live stock market exhibits a striking increase, the receipts amounting to £11,230, and exceeding 1911-12 by no less than £975. After making provision for interest on loan capital, depreciation and redemption, there remains a nett profit of £10,122.

The abattoir, with a capital of £72,624, yields a nett profit of £6,441; and the live stock market, with a capital outlay of £22,292, yields a nett profit of £3,682. It is hardly necessary to emphasise the point that the abattoir being a compulsory institution where all animals must be slaughtered, cannot be regarded as a trading concern for the purpose of exacting large profits, otherwise it would assume the unpopular role of a taxing machine, levying indirect taxation on meat. The charges are therefore regulated to yield a revenue which will cover working costs, interest, depreciation, and redemption on loan funds, and a reasonable interest on capital invested. Certain safeguards, however, require to be maintained, as there are items of expenditure which must be regarded as uncertain factors, the most important being the water question. In the event of our local supplies giving out entirely (No. 1 borehole already shows a falling off) it is estimated that our annual expenditure would be increased in this item alone by £9,000, and £6,000 of which would require to be found by the abattoir, and £3,000 by the live stock market.

The abattoir charges equal 05d. per lb. of beef, 14d. per lb. of mutton, and 08d. per lb. of pork.

During the year the Council agreed to substantial remissions, which took the form of extended hours for storage in the hanging hall, thereby relieving wholesale butchers of the necessity for renting rails.

On the instruction of the Council the price of fertilizers produced at the by-product plant was regulated so as to cover working expenses and capital charges. The Council was guided in its decision on this point by the fact that the fertilizers are manufactured from seized, condemned, and waste material.

By sale of By-Products	£2,074 3 11	
„ Stock on hand, June, 1913	697 6 10	£2,771 10 9
The cost of production of by-products was:		
To Tallow, 154,252 lbs. (per lb. = 2'0193d.)	£1,297 15 9	
„ Meat and bone meal, 286,637 lbs.		
(per 2,000 lb. ton = £7 9 7)	1,072 0 3	
„ Blood Meal, 73,303 lb.		
(per 2,000 lb. ton = £6 15 10)	248 19 4	
Profit	152 15 5	
		£2,771 10 9

These products were sold at the following rate:—
Meat and bone meal: £7 10s. per ton of 2,000 lbs.; Tallow (light) 2½d. per lb.; (dark) 2½d. lb.

A total of 957 tons of condemned and waste material was converted into 134,252 lbs. tallow, and 286,637 lbs. fertilizer; 67,225 gallons of blood was converted into 73,303 lbs. of blood fertilizer.

From above it will be seen that the live stock market is the only real trading branch in this Department, and as such yields a generous profit.

CAPITAL EXPENDITURE ABATTOIR AND LIVE STOCK MARKET.

Financial year.	Capital expenditure.	Percentage on Capital shown by nett Profit.
1908-9	£14,597 19 1	—
1909-10	17,430 1 6	6·5 per cent.
1910-11	32,695 17 8	
1911-12	69,646 2 5	8·66 „
1912-13	88,143 3 10	9·50 „
	94,916 2 10	10·664 „

Included in the ordinary expenditure are the rates of interest, depreciation, and redemption as laid down by the Council, and a ground rental of 6 per cent. on £30,000.

By profits for 1912-13 £10,122 2 10

To Capital and special expenditure,	
Abattoir and Live Stock Market	5,200 15 2
„ Contribution towards relief of rates	4,921 7 8

Taking the total population of Johannesburg, as per last Government census, at 237,220, the following statistics show a daily meat consumption of 744 lbs., or approximately ½ lbs. per head per day. This figure does not represent the actual consumption per head of Johannesburg population. A large quantity of meat slaughtered here is consumed outside the municipal area.

The following table shows the number of carcasses found to be infected with tuberculosis:—

	Slaughtered.	Tuberculous.	Per cent.
Cattle	72,122	94	·130
Pigs.	31,318	313	·967
Sheep	369,229	Nil	—

The above figures reveal that tuberculosis is gradually on the increase.

As formerly Cysticercus infestation was the principal disease rendering carcasses unfit for food. Of 72,122 cattle slaughtered, 601 cases were found to be infested; a percentage of 83.

During the year 31,318 pigs were slaughtered, and of these 3,596 had Cysticercus cellulosa infestation, a percentage of 11·482.

A considerable amount of microscopical work has been done. It has been found that this important work is greatly hampered owing to inadequate and unsuitable accommodation. A laboratory has been included in the draft plan for the new offices which will be submitted for the Council's consideration at an early date.

The question of the installation of cold storage at the abattoir still remains in abeyance. The establishment of cold storage works enables the farmer to develop the meat and mutton industry, and the development of the cattle and meat trade in Johannesburg will be retarded so long as facilities of cooling rooms are denied.

The condition of the refrigeration trucks on the railway still remain unsatisfactory, and it is impossible to conduct the dead meat trade with satisfaction if those who control the chief transit routes remain unmoved as to the absolute necessity for improvement of refrigerating trucks, and the maintenance of a controlled temperature during transit.

Every year shows an increase in the number of live stock slaughtered, and a corresponding dwindling in the quantities of frozen and chilled meat imported.

Ordinary trollies are used to convey meat through the streets. The time has arrived for a specially constructed covered-in cart for the conveyance of meat only to the different parts of the town. Draft bye-laws dealing with this question will be submitted for the Council's consideration.

MEMBERS OF THE NORTH OF SCOTLAND VETERINARY MEDICAL SOCIETY,
Aberdeen, 31 January, 1914.

On the 20th of March, 1913, the Public Health Committee resolved as follows:—

"When any Municipality having the power to enforce meat inspection charges, agrees to admit into its municipal area free of charge butchers' meat bearing the Johannesburg meat stamp, the Johannesburg Municipality will reciprocate by admitting free of charge all butchers' meat into the Johannesburg Municipal area, bearing the stamp of the Municipality concerned, both Municipalities retaining the right to stamp and subject such meat to any further inspection they may think fit."

LIVE STOCK MARKET.

The number of cattle and sheep which entered the live stock market during the past year shows a large increase as compared with 1911-12, and this increase was almost entirely due to the opening up of closed or quarantined areas. During the year the prolonged droughts seriously affected the condition of animals arriving. Although taking the condition throughout the year the numbers of prime cattle and sheep were greater than in previous years.

During the past year the number of cattle arriving has increased by 16,769; sheep have increased by 54,622, and pigs show an increase of 7,924 as compared with the previous year.

Weighing of Live Stock. All pigs passing through the market were weighed, but there seems to exist little or no desire on the part of sellers and buyers to weigh cattle.

Transportation of Stock. During the year ending 1912, 38,000 trucks of live stock were received at the live stock market.

Very little improvement has been effected in the type of truck, and there still remains a great deal more to be done in improving the condition under which live stock is transported on the railway, and in expediting the service.

Live stock in many cases is badly treated, arriving often in a bruised and battered condition, and hardly a day passes without one or more animals being found dead in the trucks. Thousands of sheep arrived suffering from catarrh, due to exposure in open trucks.

Apart from the rough handling and shunting of trucks the animals were frequently allowed to stand during transit in the sun in open trucks for long hours.

Long and serious delays in live stock trains were of frequent occurrence, and the necessity exists for immediate reforms in this direction.

The erection of two additional railway sidings and off-loading platforms to accommodate the increased traffic has been put in hand. During the period under review twenty additional cattle pens, and nineteen additional sheep pens were erected. One hundred and eleven sheep pens were roofed over.

Bye-laws for controlling and regulating the public sale of animals by the Director of the live stock market were gazetted on the 15th November, 1912, and came into force on the 1st January, 1913.

Simon, v. Director. Simon claimed the sum of £100 as and for damages caused through the defendant, in his capacity as director of live stock market and abattoirs, for having read over to Endruleenas, the plaintiff's landlord, the bye-laws relating to private live stock sale yards, whereby the said Endruleenas, on hearing the penalty clause, was induced to request Simon to desist from further carrying on his business as auctioneer, and in consequence Simon alleged he had suffered serious loss and damage. The case was tried before Chief Magistrate Mr. Buckle, and without calling upon defendant for any evidence, and on the application of Messrs. Lance and Hoyle, gave absolution from the instance with costs against Simon.

Visitors. During the year the following visited the abattoir: Minister for Mines and Education, Earl Grey, Sir John Graham, Viscount Cranbourne, the Kimberley Society of Engineers, Delegates of the Royal Sanitary Institute Congress, Delegates and Representatives from various Government Departments and Municipalities.

The system of accounting in use is well shown in an explanatory diagram. It has been the subject of many enquiries, and has been adopted by other Municipalities. It contains a number of substantial features, provides full details with a minimum amount of work, and strong counter-checks to safeguard the Council's interests. The report concludes with a summary of the conditions of the meat-producing countries of the world, and a very promising forecast for the future of South Africa.

Prosecution by the R.C.V.S.

At Clacton on Monday, before Mr. T. Lilley (in the chair), Rev. F. Beadel, Mr. J. H. Sizer, Mr. H. N. Dunnett, Mr. J. L. Corser, and Mr. G. M. Thomson.

Mr. Harry Victor Fenn, a graduate of Toronto University, and a well-known local resident, was summoned by one Alfred Pollard for "taking an addition and description, to wit, M.T.C.V.S., thus stating or implying that he was a member of the Royal College of Veterinary Surgeons, at High Street, Clacton-on-Sea, on February 2nd, 1914." There was a second summons reading: "The like thus stating that he was specially qualified to practice veterinary surgery, at the same place and date."

Mr. G. R. Thatcher, London, prosecuting on behalf of the Royal College of Veterinary Surgeons, said that on the outside of the defendant's premises was a brass plate bearing the words "H. V. Fenn, M.T.C.V.S." Under the Veterinary Surgeons Act of 1881, the defendant had no right to put such letters after his name. In the present case the defendant was using the addition or description to imply that he was a member of the Royal College of Veterinary Surgeons. The facts were somewhat unusual. He understood that the defendant alleged that the letters meant that he was a member of the Toronto College of Veterinary Surgeons. As a matter of fact there was no such college; but there was a college situated at Toronto known as the "Ontario Veterinary College, Limited." The College issued diplomas, but they were not recognised in England, the course of study being two years in Ontario while in England it was four years. There was a real distinction and not a technical distinction. The real point was that he was misleading the public. He noticed that in the Clacton Directory it was stated "H. V. Fenn, M.R.C.V.S." He did not know whether it was a misprint.

Alfred Pollard, solicitor's clerk, residing at 56 Station Road, Clacton, said he inspected the defendant's premises in High Street on February 2nd last. The defendant carried on business as a veterinary surgeon, apparently, as indicated by the plate outside inscribed "H. V. Fenn, M.T.C.V.S." He produced a copy of the year book for Clacton and on page 87, was the entry "Shotley House, H. V. Fenn, M.R.C.V.S.," also a bill which stated "Dr. to H. V. Fenn, M.T.C.V.S." and a copy of the Veterinary Surgeons Register, but the defendant's name was not included in it.

Defendant said he never authorised anyone to put his name in the Directory.

The Magistrates' Clerk remarked that Mr. Thatcher had said it appeared, but it might have been a printer's error.

Defendant said that the letters he had had inscribed on his plate represented that he was a member of the

Toronto College of Veterinary Surgeons, Canada. He had his certificates to show and he would never have attempted to put the letters on the plate had it not been that four years ago he called on Mr. Bullock, Secretary to the Royal College of Veterinary Surgeons, at 10 Red Lion Square, London, and asked him if his Council had any objection to witness putting on his plate "M.T.C.V.S." Mr. Bullock replied, "Are you a graduate of that College?" and witness answered "Yes, I am, 1893, three years course." Mr. Bullock then said "I do not think they can stop you putting them on so long as you don't put "veterinary surgeon" on that plate." Witness came back to Clacton and gave an order for the plate to be affixed. He had never at any time represented himself as "Member of the Royal College of Veterinary Surgeons, London." Last Friday week witness was plaintiff in a slander action at Chelmsford when a few questions were asked regarding his degree, and Justice Bray said if witness was a graduate he did not see what harm witness could be doing in putting "M.T.C.V.S."

The Magistrates' Clerk said he was present on the occasion referred to, but he did not remember that remark being made; if it was then the learned Judge was wrong.

Defendant, continuing, said the plate had been up four years; why didn't they take steps before?

Mr. Thatcher: That is not evidence.

The Chairman: Are you going to call Mr. Bullock? Defendant: Certainly not.

The Magistrates' Clerk: If this gentleman did tell you that, he told you something that was wrong. Would you like to have an adjournment to call this gentleman, but then I do not think this will be any answer to the case as everyone is supposed to know the law.

Mr. Thatcher said he had seen Mr. Bullock, but that gentleman mentioned nothing about what Mr. Fenn had said.

The Chairman: Do you wish for an adjournment?

Defendant: No, I do not wish for it. He had never used "veterinary surgeon" since he was prosecuted four years ago.

The Magistrates retired for private consultation and on their return the Chairman said they found the defendant guilty of the offence and he would be fined £5 and 4s. costs. This was not the first occasion and he (the Chairman) would like to point out, that if the plate continued defendant would be liable to a penalty of £20.

Defendant asked to be allowed to the end of the week in which to pay, which request was granted.

On leaving the Court the defendant remarked in an undertone that he was very much obliged to the gentlemen who had moved in the case. He thought he now knew who they were.—*The Illustrated Clacton News*.

[We are informed that Mr. Bullock absolutely denies that any such conversation took place as alleged by the defendant. Further, that the statement made by Fenn was not on oath].

Women Solicitors—A Coming Bill.

A Bill has been drafted, and is to be introduced, if possible, in the present session, for removing the existing disability of women to enter the legal profession. The Bill is the outcome of the recent decision of the Court of Appeal that women were not entitled to enter the legal profession, for the simple reason that there had never been a woman solicitor, a negative fact which, it was held, had become part of the common law of England. The Master of the Rolls expressed the view that it was for Parliament, and not for the judges, to remove the disability.

Miss Babb and the three ladies who had joined with her in bringing forward the test case, Miss Costelloe, Miss Ingram, and Miss Nettlefold, devoted their energies to getting a Bill drafted, and a committee has been formed, among its members being Lord Wolmer, M.P., Lord Robert Cecil, M.P., Mr. J. W. Hills, M.P., Mr. George Radford, M.P., Mr. S. Garrett, and Dr. Jane Walker. The committee has sent a letter to every Member of Parliament urging the justice of the admission of women to the roll of solicitors, and enclosing a copy of the proposed Bill, which consists of two short clauses.

The committee point out that the profession of solicitor is one which women are clearly fitted to practice, and where they would be doing work for which there is already a need and a demand. It is further contended that the contemplated alteration of the law is required to meet the changes brought about by modern conditions. Women are now educated and expected to earn their own living. It is no longer right, therefore, to keep shut against them any profession which they are qualified to practise.—*Daily Telegraph*.

Glanders in London.

During the five weeks ended January 10th, there were 106 cases of glanders in London reported by the County Council's veterinary inspectors. All the animals were slaughtered, and compensation amounting to one-half of the value of the animal was paid to the owner in each of the 102 cases in which the disease was diagnosed by the mallein test. In the remaining 4 cases, which were diagnosed clinically, minimum compensation of £2 was paid. The number of animals slaughtered during this period is due to a serious outbreak in the stud of a firm of carmen and contractors. The first indication was obtained through a horse cast from the stud being found, three weeks after purchase, to be affected with the disease, and on the firm's horses being tested throughout 89 animals in all, out of a stud of about 250, were slaughtered. This particular stud had never been previously tested with mallein by the L.C.C. inspectors, and there was nothing in the general appearance of the horses to anticipate a disclosure of the disease.

About Tuberculosis and the Order.

At a meeting of Council of the British Dairy Farmers' Association, Sir Sidney Pocock, J.P., the Association representative on the Tuberculosis (Animals) Committee, reported what had been done by that body, and with regard to the statistics that were to hand on their investigations up to the end of September last, to the effect that out of 8,162 cows that were tested only 220 samples of milk were found to be tuberculous. After the way the public had been cautioned by scientific men against drinking milk which might be affected, and generally frightening them, it was the duty of the Association to disillusion their minds, as it was not so very terrible after all, taking into consideration the fact that it had not yet been proved that the milk from a cow with a tuberculous udder could transmit the disease to human beings. He considered the public had been frightened unnecessarily. The cost of administration and compensations paid amounted to £11,998, of which only £3,246 was for compensation when the animals had been slaughtered, which was a very inadequate amount to compensate the farmers according to the scale fixed by the Board of Agriculture, and the Order had proved a failure in many respects. It is proposed to discuss the matter further when the figures for the end of the year are available.

NOTE.—The figures for the Current Year are approximate only * As Disposed or Exposed to Infection

The R.A.S.E. Demonstration: Steamed Milk.

At the monthly Council of the Royal Agricultural Society of England, in the Veterinary Committee:—

The Earl of NORTHBROOK reported his election as Chairman for the year.

The Committee recommended that a donation of 25 guineas be made by the Society to the funds of the Organising Committee of the Tenth International Veterinary Congress to be held in London this year.

On the motion of Mr. Mansell, seconded by Mr. Stanyforth, it was resolved:—

"That a letter be addressed to the Board of Agriculture expressing the opinion that as sheep scab has now been reduced to comparatively narrow limits, the time has arrived when regulations of a more drastic character should be introduced by the Board with a view to the complete eradication of this disease from the country."

TUBERCULOSIS EXPERIMENT.

The Earl of NORTHBROOK said that the report had been presented at the last meeting, but that any discussion had been postponed until the present meeting. The report was extremely clear, and the appendix to it gave all the details of temperatures and the various examinations, with the results of those examinations.

Mr. MIDDLETON said that it was with regret that he rose to say a few words against the report, but he did not think that its circulation would do the Society any good. He had been from the first opposed to the demonstration, for the reason that it had already been

proved that healthy cattle could be raised from tuberculous parents if they were kept away from all sources of infection. He was not at all sure that the cure was not worse than the disease.

Mr. ADEANE said that he was responsible for moving that the demonstration be carried out. He would like to state that he could not agree with what had fallen from Mr. Middleton. Of course, it was a personal view, but he thought the experiment had been extremely valuable, and very satisfactory as a demonstration. They were not all so fully alive to the diseases of animals as Mr. Middleton supposed. He hoped that the report would be widely circulated, and that some steps would be taken to advise farmers throughout the country, who undoubtedly had a great deal of disease throughout their herds, how best they could treat it. He would like the Veterinary Committee to draw up some scheme of advice for farmers. He happened to know, having had to purchase cattle in the North of England, that there existed tuberculosis—or whatever caused reactions, whether tuberculosis or not—all over England. He thought the report valuable, and that they should do all they could to extinguish the disease.

Mr. BROCKLEHURST said he would like to ask one question. He thought the members of Council would see that nearly all the calves were attacked with white scour, and that he would like to ask whether that was due to the fact that the milk was sterilised. There had been a good deal of correspondence in the papers lately suggesting that the sterilisation of milk, although it destroyed the bacillus, at the same time destroyed the nutritive value of the milk.

Sir JOHN M'FADYEAN, referring to Mr. Brocklehurst's question, said that, so far as he was aware, there was no experience and no experimentation to support the view that milk from the nutritive point of view was injured in any way by steaming or boiling. One had frequently seen statements to the contrary within comparatively recent times, but his strong impression was that the people who published those views had not taken the trouble to examine the evidence. He was perfectly certain that one could say, by what had actually happened, that not only calves but children could be reared on milk that had been steamed. Thousands of calves had been reared on steamed milk. He did not himself think there was any connection whatever between the use of the partially heated milk employed in the experiment and the occurrence of white scour. It was a well-known fact that every year outbreaks of white scour occurred throughout the country, and broke out in animals under the most diverse conditions. White scour was practically always a bacterial disease and infectious, and they had been the victims of misfortune in their experiment. He denied strenuously, and he hoped the opinion would not be put about, that those calves died because the milk had been heated to about 200 deg. Fahrenheit. He was sure the Council hardly wished him to express any opinion as to the value farmers would place on the experiment, but he thought he might be allowed to say that Mr. Middleton was in error in supposing either that young cattle were less susceptible to tuberculosis than older cattle, or that there had been any occasion whatever to keep the animals alive any longer than they did in order to see whether tubercle bacilli had been inherited from their parents. It was an old view as to the latency of tuberculosis, but he thought it had been entirely discarded by all people who had studied the question in recent years. It had been said in pre-bacteriological days that the germs were generally communicated by tuberculous parents to their progeny, the fact that the disease did not disclose itself in early life being explained by saying that the germs in young human beings or young cattle for some reason or other had their development restrained, and did not multiply until the individual was approaching adult life. That was absolutely contradicted by experiments. As a matter of fact, it had been found that tubercle bacilli developed and multiplied quicker in young cattle than in old cattle. Tuberculosis was less frequent in calves than in old cattle, but that was because young stock were not exposed to the same risks, as older cattle were more closely housed along with animals already tuberculous.

Lord NORTHBROOK said that he was in rather a peculiar position, for in 1910 he opposed Mr. Adeane's proposal, as he had thought it unnecessary to spend their money demonstrating a fact already acknowledged by all persons who had given serious attention to the subject. Up to that point he agreed with what had fallen from Mr. Middleton, but as the Chairman of the Committee that carried out the demonstration, he could not follow Mr. Middleton in his further expression that it would be better for the report not to be circulated. As to whether or not they would succeed, as Mr. Adeane and Mr. Mansell hoped, in convincing farmers that it would be possible to rear healthy stock from reacting parents—a fact they would not believe when it was put before them by experts—he could not express an opinion, but he did think the report had a great deal of valuable information in it that would be of great interest to the stockbreeders of the country. With regard to what had fallen from Mr. Adeane that some sort of epitome should be drawn up by the Veterinary Committee, he would say that that should have their consideration.

The report on the Tuberculosis Experiments was then adopted.—*Live Stock Journal*.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, Aug. 3—8, 1914.

At a meeting of the Executive Committee, held at the Royal College of Veterinary Surgeons, 10 Red Lion Square, London, W.C., on Monday, February 9th. Present: Sir John M'Fadyean in the chair, Colonel J. Moore, Major A. G. Todd, Prof. G. H. Wooldridge, Messrs. Alex. Crabb, H. A. MacCormack, T. S. Price, J. Willett, F. Bullock, and Sir S. Stockman (honorary secretary).

Constitution. The CHAIRMAN reported the constitution of the Committee as follows: Resolution of the Organising Committee, January 9th, 1914:

"That the following be appointed an Executive Committee, with power to add to their number:—Chairman, Honorary Secretary, Treasurer, Messrs. Banham, Barrett, Crabb, Hobday, Jackson, Col. Moore, Messrs. MacCormack, Price, Willett, and Prof. Wooldridge."

The HON. SECRETARY explained that each member of this Executive Committee would probably have to take up at least one particular matter in connection with the Congress which would require his constant attention, including a good deal of running about London. On this account most of the members of the Committee had been chosen from amongst those who lived in or near London. The Committee would have to be extended in order to avoid its members being over-burdened.

A discussion took place regarding whether it would not be advisable to ask members resident at a distance from London to join the Committee, especially having regard to the fact that it was proposed to institute excursions after the Congress to Ireland, Scotland, and various parts of England.

It was resolved:—That the Secretary be instructed to ask the Veterinary Medical Association of Ireland to nominate representative veterinary surgeons to the number of eight to the General Organising Committee in addition to those who are already members, and four to the Executive Committee.

Reporters. A list of reporters up-to-date was also considered, and it was resolved to ask Mr. Prentice of the Irish Department, to act as reporter on the subject of swine fever, or, if he found himself unable to do so through pressure of work to suggest a member of his staff.

Invitations. It was resolved:—

(a) That invitations be addressed to all Municipal Corporations and County Councils employing a whole time veterinary surgeon, inviting the appointment of a delegate to the Congress, the delegate's fee being fixed at £1.

(b) That the Colonial Office be requested to issue invitations to Veterinary Schools in British Dominions.

(c) That invitations be addressed by the Honorary Secretary to the Governors of British Veterinary Schools.

(d) That all Breeding and Agricultural Societies who have been invited to subscribe, and who have subscribed to the funds of the Congress, be asked to appoint a delegate to the Congress.

(e) That the Honorary Treasurer be instructed to invite subscriptions from the British Dairy Farmers' Association, and from the Kennel Club.

Exhibition. The queuing of the allotting of space for the proposed exhibition of drugs, instruments, etc., was considered, but the matter was adjourned to the next meeting in order that plans of the space available might be obtained.

Excursions. Prof. Wooldridge submitted estimates for excursions supplied by Messrs. Thomas Cook & Son, and, after discussion, it was resolved that the following excursions be arranged:—

- (a) Excursion to Windsor on Saturday afternoon, August 8th.
 (b) Excursion to Pirbright on Sunday, August 9th, or Monday, August 10th.
 (c) Excursion to Cambridge and Newmarket on Monday and Tuesday, August 10th and 11th.
 (d) Excursion to Oxford and Stratford-on-Avon on Monday and Tuesday, August 10th and 11th.
 (e) Excursion to the Isle of Wight and the New Forest, Wednesday—Friday, August 12th—14th.
 (f) Excursion to Scotland and the Lakes, Monday to Saturday, August 10th—15th.
 (g) Excursion to Ireland, including Killarney, Monday to Saturday, August 10th—15th.

The question of arranging for parties to visit places in London was referred to the Ladies Committee.

The consideration of other matters on the Agenda was referred until the next meeting.

Foot-and-Mouth Disease.

The existence of foot-and-mouth disease was confirmed on Sunday, the 22nd, amongst cattle at Bradley Green, near Redditch, County Worcester.

The existence of foot-and-mouth disease has been confirmed on Monday, 23rd inst., amongst cattle on two separate premises in the City of Liverpool.

Precautions were taken to prevent the spread of the disease, and an Order has been issued prohibiting the movement of animals in the City of Liverpool and in a large area surrounding the city.

In the House of Commons on the vote for the salaries and expenses of the Irish Department of Agriculture, Mr. RUSSELL said: "It was a remarkable fact that at no other landing place, except Birkenhead, was any disease of the kind discovered—(Nationalist cheers)—although these animals also came from the same quarters of Ireland. In the inquiry that would take place that fact must bulk largely. All the animals shipped from Ireland were carefully examined. In ten days the inspectors had critically examined 37,000 animals in different parts of Ireland, but had not found a single one affected with disease of any kind."

With regard to the Redditch outbreak, the cattle left Ireland on Jan. 30. They were kept at Birkenhead for eight or nine days, and no case of disease was discovered until last Saturday. If the disease came from Dublin that would give an incubation period of 21 days—a period never heard of in the history of the disease."

Anthrax at Denton, Cheshire.

On Friday last a case of anthrax at Henfold Farm, Denton, was discovered by the sanitary inspector (Mr. Brocklehurst), who immediately reported the matter to Police-Sergeant Birrell, and to the Council's veterinary surgeon, Mr. New, of Ashton-under-Lyne. The latter made a microscopical examination of the blood specimen, and diagnosed the case to be one of anthrax. The county authorities' veterinary surgeon took a portion of the spleen for microscopical purposes, and pronounced that the cow had died from anthrax. The Board of Agriculture have confirmed the opinion. The police had the carcass destroyed by fire, and the premises and surroundings thoroughly disinfected. The most stringent precautions have been taken. We understand that it is 30 years since a case occurred in Denton previously. The more serious aspect of the case is that a local butcher has contracted the disease, and has been removed to the Manchester Infirmary.—*The North Cheshire Herald*.

A "Side-issue" in Surgery.

"It is rather remarkable that though there have been many experimental researches on the subject of fractures and their healing, almost all of these have had relation to the origin and formation of callus; and none, as far as I know, have been carried out to test the principles of the operative treatment. Experiments on animals cannot tell us much about non-operative treatment of fractures, because such treatment leads to so much deformity that in veterinary practice an animal with a bad fracture is not treated, but killed. But they can give us information about the operative fixation of bones, which is to be obtained from no other source, and as a side issue this study will provide, for any who care to take it up, a perfectly efficient method of treating the broken bones of animals, so as to save for usefulness and breeding many a valuable horse or dog."

[In a lecture on "The Operative Treatment of Fractures," by Mr. Ernest W. Hey Groves, M.S.LOND., F.R.C.S.ENG., Hunterian Professor of the College.]—*The Lancet*.

Queensland, Australia, takes the premier place in the Commonwealth for cattle, and its stations may be found from the southern border below Cunnamulla to Cape York, and from Bowen to Burketown, the herds now numbering about 35,000, comprising 5,210,891 head, the question of the future is important. The demand for fat stock is very active, and likely to advance, not only for the meat works of the State, but for the works in New South Wales, where they are slaughtered and frozen and shipped in direct liners to supply the Canadian and American trade. Much of this export trade might be kept within the State if a direct line of steamers were running from Brisbane to Vancouver or San Francisco.

Personal.

Mr. C. C. NESLING, M.R.C.V.S., Framlingham, is Secretary for the Framlingham Live Stock Show (July 23).

His Majesty the King held a Levée on Feb. 24th, at St. James' Palace. The following presentations to the King were made, the names having been previously left at the Lord Chamberlain's office, and submitted to His Majesty for approval:—

Lieut. A. J. Curtis, Army Veterinary Corps (T.F.), by Maj. R. A. Newill.

Mr. Frederick Hobday, F.R.C.V.S., Hon. Vety. Surgeon to the King, by the Master of the Horse.

The following Noblemen and Gentlemen attended the Levée:—

* * * *

Vet.-Maj. E. P. Barry.

CORRESPONDENCE.**"SUITABLE APPLICANTS" FOR COLONIAL APPOINTMENTS.**

Sir,

I have just been reading an extract in your number of December 27th, 1913, from *The Friend* (Bloemfontein) containing remarks said to have been uttered by Dr. Theiler at the African Club, Maritzburg, which I think cannot have been correctly reported, or, if they have been so, then I think they are rather unfortunate remarks and calculated to create a wrong impression.

As a former student under Dr. Theiler in Pretoria, I cannot seriously believe that "he intends to look to young South Africans for assistance in research work in South Africa." No doubt motor cars are partly responsible for a falling off in intending veterinary students, but whilst this undoubtedly deters them from thinking of private practice, it will certainly not act as a deterrent for Colonial veterinary research work.

We hear on all sides that never was there such a demand for the Colonial veterinary man, and yet with men holding the diploma of the R.C.V.S. and the post-graduate diploma specially designed for such men, we are asked to believe that suitable men cannot be obtained. If it is a fact we must look for the cause, and not accept wild statements. Either it is suggested that the expensive, protracted training that qualified men have put themselves to is not up to the standard required when they offer themselves for colonial work, or there is some objection on the part of an otherwise suitable candidate to the conditions of service.

The first suggestion is a very serious one and hardly likely to be true, casting, as it would, very serious aspersions on the teaching at the veterinary schools which is not warranted, and reducing the post-graduate course to a farce.

Dr. Theiler is intimately conversant with this teaching, and he would, I feel sure, be the last to question the thoroughness of the knowledge imparted by his colleagues at the schools, or to suggest that diplomas are granted to men unfitted to hold them.

Veterinary research work is a special branch of the profession, and it is not possible for any College or Post-Graduate Course to turn out the "finished bacteriologist" in this respect any more than it is possible to turn out the young graduated M.R.C.V.S. of 21 with the practical experience of a man twice that age. The qualified aspirant for colonial veterinary work, just as his private practice colleague, starts with a good ground work of knowledge, which is the framework his practical field experience will be built upon. This experience can only be obtained by practical work at the seat of disease and under conditions in which this disease exists in its natural haunts abroad. A man may be

excellently equipped with the knowledge, but the conditions under which he will be called upon to successfully apply it in a rough country will often turn out to be very different to the glowing picture conjured up in his mind on reading the terms of the appointment. There are many points that crop up to rob the "fine berth" of some of its glossiness when he reaches the seat of his labours, and he may often wish he had not jumped so quickly at the gilded bait before striking a better bargain with the authorities at home.

In a good many Colonies where the Veterinary Department is firmly established on its own basis, with a practical veterinary surgeon at its head, the conditions leave very little to be desired; but, in other cases, where the veterinary department is only an "offshoot" of another department, its services are not suitably recognised or the remuneration in proportion to the work expected of them.

In one Colony where the veterinary is a branch of the medical department, the highest pensionable salary the veterinary surgeon can attain to is £540, and this only after 12 years service; whereas his medical confrères attain to £720, after which the following promotions are open to them, viz., one at £1,020 to £1,200 and four at £800 to £1,000. The argument I have heard used in this case is that human life is more valuable than animal. Nobody wishes to contradict this, but we, as responsible for the animal kingdom, are called upon to undertake hardships and inconvenience "up country" that are not associated with the medical work. We have our own microscopical diagnosis and other scientific work to do in our own sphere similar to that of the medical, but carried on often under far less auspicious circumstances.

A lot of "soft soap" is always dished out at dinners when a medical officer, in proposing the health of the veterinary profession, invariably comments in congratulatory terms on the immense strides that scientific veterinary research has made. He is quite right, but when the two departments are working side by side in a colony and both turning out good work, why is this invidious distinction made?

No, sir! do not let us hear any more sentimental "clap-trap" about not being able to get suitable men; there is very little lack of them, but, as reasonable men, they expect their professional services to be suitably remunerated, and are at present prepared to say "No, thank you." It is about time the veterinary profession came into line and had our services properly recognised. The medical have always shown us the way in fighting for what they want and they get it, and it is up to us to get even; the sooner this is done the better.

Some who have jumped at a "gilded pill" of £300 to £400 abroad have learnt to their cost that all is not gold that glitters; it is not for them to grumble, and they signed on with their eyes open (or should have done), but having jumped into the soup themselves there is no reason why they should not warn other impetuous individuals to pause and consider well first.

Some of us are egotistical enough to consider that our services in our own department are as valuable to a colony as the medical. The Government as yet have not seen it in that light; we should be greatly obliged if they could be made to. As officials we are not able to openly agitate, but we pin our faith on those at home who "father" the appointments to help us. Why not have a Commission to enquire into this dearth of applicants for Colonial appointments?

Assuming there is a dearth, so much the better for those who apparently are suitable at present, they are in a better position to dictate suitable terms. I think the time has arrived when the subject of adequate payment for colonial service should be gone into, and the veterinary departments placed on their own footing in colonies where at present they are merely "off-shoots."

When this is done I think the "scarcity of suitable men" bogey will have been exploded, and the conditions of some appointments will not have to be "veiled" to conceal the fact that the applicant is required to serve in a certain place that would "crab" the post at once if openly admitted.—Yours very truly,

"EAST OF SUZ,"

January 23rd, 1914.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1339.

MARCH 7, 1914

VOL. XXVI.

THE PROFESSION AND THE STATE.

From time to time we have reprinted portions of the reports of Indian and Colonial State veterinary departments; often we have had to pass over others unnoticed in our pages, owing simply to exigencies of time or space. Much that is included in these reports only appeals directly to a relatively small section of our readers, yet there is always something, either directly or inferentially, of general professional interest in them—those we print this week help to summarise the progress of protective inoculation in a large field.

But there is one outstanding feature common to all of them—they are records of work faithfully done; work unquestionably of considerable value to the State, although their money value cannot be definitely stated.

These men are diplomates of the R.C.V.S., graduates of our teaching colleges; and it is a fair inference that other men in the profession, to whom the opportunity for such work has not fallen, are equally capable. Do not these records go far to justify the claim of our profession to a better recognition than it has yet received? A young profession—our first Charter is dated just 70 years ago; numerically small—our Register carries 3408 names; with a range of work from that of the country practitioner with farm animals for the bulk of his patients, to those aiding the Public Health work of our cities with populations of three-quarters of a million, and the men in charge of the animal health of huge districts in India and the Colonies; yet the Tuberculosis Order, 1913, is the first official acknowledgment in this country of our capacity to serve the State in a larger measure.

MR. MOND ON TUBERCULOSIS IN COWS.

During the last month or two paragraphs and letters have appeared concerning the views of Mr. Mond on the sterilisation of milk and the production of a pure milk supply. This week we report an address to a meeting of Cheshire farmers in which Mr. Mond gives a fuller exposition of his views, with some remarks on the value of the tuberculin test and on tuberculosis in cows. With the results of sterilisation we are not immediately concerned, but the remarks on the disease in cattle are likely to prove mischievous, for they deal with a part of the question only—the transmission to man, or rather to infants, and only tend to confuse the question of the animal disease.

Reports, both in this country and abroad, testify to the varied and often unsuspected manifestations of the disease in animals. For years past practitioners have striven against the dissemination of

tuberculosis, with almost daily experience of neglect of the disease and its infectious nature by farmers, many of them ignorant, many careless, and nearly all very humanly objecting to destroy property which they could turn into money. Mr. Mond tells them that tuberculosis is of little importance; that he would not hesitate to sell an animal which reacts to the tuberculin test in a market; that probably not more than 5 per cent. of the cows suffer from anything which may decently be called tuberculosis: that milk from a reacting cow is no worse than another unless emaciation or other unfavourable symptoms supervene.

How well these pronouncements jumped with the views of his audience may perhaps be judged by the fact that they accorded him a vote of thanks by rising and singing "For he's a jolly good fellow."

PHARYNGITIS, WITH CERVICAL ABSCESS OPENING INTO THE TRACHEA.

Janin reports (*Journal de Méd. Vét. et de Zootechnie*) the following case. During the course of an epizootic of angina and phlegmonous pharyngitis, a horse was brought into the infirmary with a temperature of 102° F. The animal was salivating abundantly, but the appetite was good.

After two days the salivation disappeared, but the temperature rose to 104.7° F., and a discharge, which was evidently alimentary, was rejected by the nostrils. Deglutition was difficult, and the pharyngeal region was very sensitive to pressure, clearly indicating pharyngitis. This was treated by applying a blister round the throat, and administering an electuary composed of honey and turpentine.

During the following days the appetite persisted, but the dysphagia was so great that all oats were rejected by the nostrils in a dough-like form, and the unsuccessful attempts to swallow were invariably succeeded by a fit of coughing.

In the other animals affected during the epizootic, the disease had always taken a rather rapid course, and although sometimes the symptoms had been alarming, had always terminated in a clear resolution. The case in question took a different course. The symptoms persisted, though they became much less acute, and a dry and intermittent cough, with a mucous nasal discharge which on rare occasions was very slightly purulent, threatened the establishment of a chronic pharyngitis.

A seton was now inserted into each parotid region. A diffuse puffiness then appeared on the left thyroid region, and was explored with a trocar without result. During the following days this swelling remained stationary, almost insensitive,

showing no fluctuating point, and causing no trouble to the animal. Two further attempts to discover fluid within it were made by incising the skin and lacerating the subjacent tissues, but no success was attained. Nevertheless the horse preserved good spirits and a certain amount of appetite, till one morning he was quite unexpectedly found dead in the stable.

Post-mortem, in addition to lesions of secondary importance, it was found that the region corresponding to the posterior part of the larynx and to the first rings of the trachea was hidden in an œdematous lardaceous connective tissue which surrounded all the muscles of the tracheal region and also the thyroid bodies, particularly the left one. The larynx and the trachea could only be isolated by excising a veritable fibro-œdematous "muff," and some of the tracheal rings were damaged during this operation. On the left side the jugular and carotid were completely shut in, as was also the œsophagus, the fleshy tunic of which was united to the reactional fibrous tissue.

Between the neck and the posterior part of the trachea was an abscess, bulging to the left, and extending exactly from the third to the eighth tracheal ring. The pus had penetrated the posterior part of the trachea between the third and fourth rings, had then burrowed underneath the tracheal mucous membrane from the third to the sixth ring, and had finally penetrated into the trachea by two oval and closely adjacent openings, which appeared as if cut by a punch.

The original abscess had resulted from suppuration of the most posterior lymphatic glands of the left retro-pharyngeal group, or, more probably, of the small middle cervical glands. The abscess, protected by the trachea and tracheal muscles, and encysted in fibro-lardaceous reactional tissue, had not been reached by the repeated surgical explorations, and had finally burst into the trachea.

The case teaches that deeply situated abscesses behind the trachea should never be left to take their own course. They should be operated upon early by a careful dissection, so as to reach the purulent centre without injuring the important structures of the jugular furrow.—(*Annales de Méd. Vét.*)

A SPECIFIC EPIZOOTIC FORM OF NECROBACILLOSIS IN THE GOAT.

Pesadori describes (*La Clin. Vét.*) a very contagious affection of the claws, peculiar to goats, which appeared in some Calabrian districts at the beginning of last winter, and affected about 10,000 animals in the course of two months. Sheep and cattle, kept under the same conditions as the goats and constantly exposed to infection, remained free from disease.

The disease begins by a limping upon one hind foot, and a few hours later the animal is going upon three legs. The cleft of the claws and the rim of the coronet swell considerably, and the foot is hot and sensitive to pressure. A fluctuating centre soon appears at one point, opens, and discharges a

crumbly, thick, dirty pus, mixed with blood and shreds of necrotic tissue. The animal is depressed, refuses food, groans, and is feverish. The fever is slight at the commencement, and afterwards increases with the extent and severity of the lesions of the claws. She-goats with kids lose their milk during the acute stages, and pregnant animals sometimes abort.

If the disease is neglected, the necrotic and suppurative process extends and leads, if no operative interference is undertaken, to septicæmia and death. If treated early with disinfectant, astringent, and desiccant agents, the disease takes a comparatively short and mild course, lasting about eight to twelve days. But it often occurs that, after healing of one foot another becomes affected, and the animal then loses greatly in condition, and not rarely dies of marasmus.

The cause of the disease is probably the necrosis bacillus, which finds entry into the organism through slight solutions of continuity in the horn of the claws and in the cleft of the claws. Extreme moisture of the ground, by its softening and loosening action upon the horny tissues, favours infection.—*Berliner Tier. Woch.*

DERMATOMYOMA IN A CAT.

The dermatomyoma or dermatoleiomyoma is usually a multiple tumour, and is very slow and benign in its evolution. It is very rare in man, and hitherto unknown in animals.

Ball now records (*Journal de Méd. Vét. et de Zootechnie*) the following case in a six-year-old cat. Behind the shoulder, to the right of the middle line of the back, was an oval neoplasm about 3.1-5th inches long by 2.2-5th inches broad, involving both the skin and subcutis. The skin, which was in union with the neoplasm, showed a certain degree of alopecia; it appeared slightly translucent in one point, near which was a fistulous orifice giving exit to a yellowish-brown purulent liquid. The neoplasm was firm in consistence, but was hollow; its centre was traversed by an elongated cavity following its grand axis.

On the left side of the thorax was a second neoplasm, similar to the first, but smaller.

Histologically, these neoplasms were found to be dermatomyomata. They were constituted by clusters or bundles of smooth muscular fibres running in all directions, and united by an insignificant framework of connective-elastic tissue.—(*Annales de Méd. Vét.*)

NEOPLASMATA IN THE TESTICLE.

R. Galli describes (*Il nuovo Ercolani*) several of these cases. One was an enchondroma of the left testicle in a three-year-old colt. The tumour had a lobulated appearance, and consisted of a fibrous tissue, in which numerous islands of hyaline cartilage, often ossified in the centre, were imbedded. The cartilage cells, most of which were uninuclear, were generally round or oval, but occasionally also they were spindle-shaped. In the neighbourhood of the islands of cartilage, between the connective tissue fibres, young round cells occurred which ap-

peared similar to sarcoma cells. Fat occurred in places, in both the connective and cartilaginous tissue.

The testicle felt lumpy when palpated. It was rounder in shape than usual, in consequence of an increase in its transverse diameter; and it weighed 160 grammes (= about 5.5-8th oz.) The epididymis was atrophied.

Three cases of fibroma of the testicle are also described. Two were in asses, one in a horse. All three animals were of advanced age. The tumours were benign fibromata, hard in consistence, and ranging from the size of a pea to that of the fist. They commenced from the tunica albuginea, and were either attached to the testicle by broad surfaces or adhered to it in the form of cords of varying thickness. In one case (an ass) both testicles were affected, the right one weighing 385 grammes and the left 207 (very approximately these weights equal 6.7th lb. and 3.7th lb.—(*Berliner Tier. Woch.*)

W. R. C.

"A DESCRIPTION OF THE IMPERIAL BACTERIOLOGICAL LABORATORY, MUKTESAR: ITS WORK AND PRODUCTS."—By Major J. D. E. HOLMES, M.A., D.Sc., M.R.C.V.S., Imperial Bacteriologist. Calcutta: Superintendent Government Printing, India, 1913.

[ABSTRACT.]

In 1890, the first step was taken towards providing facilities for the investigation of the diseases of stock in India. Dr. Lingard was appointed as Imperial Bacteriologist in connection with the Laboratory at the College of Science, Poona. His duties were thus defined.

"To investigate diseases of domesticated animals in all Provinces in India, and to ascertain, as far as possible, by biological research both in the Laboratory and, when necessary, at the place of outbreak, the means for preventing and curing such diseases."

For some years Dr. Lingard worked in the Poona Laboratory mainly on the investigation of Surra in horses. He found, however, that the climate of the plains rendered laboratory research work extremely difficult and was also little suitable for the manufacture and preservation of vaccines and serums. Consequently, in 1893, it was decided to remove the Laboratory to a suitable site in the Hills, and Muktesar was selected for this purpose.

In 1895 the Laboratory main building (part of which was used by Dr. Lingard as his residential quarters), a post-mortem house, two out-houses, one cattle shed, a bungalow for the Assistant Bacteriologist, and an out-Kraal for cattle were completed. The staff consisted of the Imperial Bacteriologist, Assistant Bacteriologist, one native laboratory assistant, three clerks, one artist and some menials. At this time the investigation of rinderpest and measures of prophylaxis were taken up, and in the following year Professor Koch, at the request of the Government of India, visited Muktesar and demonstrated his bile method of inoculation against rinderpest. During the following three years rinderpest, and the methods of preparing a potent antiserum, were further investigated. Two more cattle sheds, a sterilising house, snow well and cold room were added to the buildings.

In 1898 Dr. Lingard was compelled to return to England on sick leave for two years. During this time Major Leonard Rogers held charge of the Laboratory and continued the experiments on rinderpest antiserum.

In 1899 a fire broke out in the western end of the laboratory and the whole building was completely burnt down. The reconstruction of the laboratory was at once commenced. A water supply scheme was taken in hand, and also sanction was obtained for the establishment of a branch laboratory at Bareilly, for the purpose of carrying out certain investigations during the winter months of each year.

A potent rinderpest serum having been prepared, and its application in outbreaks of the disease having met with success, a large and increased demand for the serum arose. To provide facilities for the preparation of a sufficient supply of the serum, more cattle sheds, and out kraals were built, the staff was also increased and more land was taken up for the accommodation of cattle and providing fodder.

In 1898 Mr. Kriebel was appointed Head Laboratory Assistant, and posts for two veterinary assistants and a farm jamadar were sanctioned.

In 1901-2 Lieut. Holmes relieved Lieut. Walker as Assistant Bacteriologist.

From 1901-1904 the preparation of antisera for anthrax and hæmorrhagic septicæmia, of blackquarter vaccine, and of mallein were added to the list of work. Further accommodation was provided for this increase of work, a second European laboratory assistant was engaged, and other additions made to the staff. Oil engines and large centrifuges were installed and the gas and water pumping plant increased.

In the following years the demand for the products of the laboratory rapidly increased, and further accommodation had to be provided for the serum-preparing animals.

Three small out-laboratories for anthrax, blackquarter, and glanders were built and, at a later date, another wing was added to the main building.

A course of instruction in tropical veterinary diseases and in serum therapeutics was commenced for officers of the Army and Civil Veterinary Department. A bungalow for their accommodation was built. Each month a class of about six native veterinary graduates was instructed in the methods of serum injection and in the practical application of serums and vaccines. Quarters were provided for these men.

In 1907-8 Dr. Lingard retired, and Capt. Holmes was appointed Imperial Bacteriologist.

An Institute and tennis grounds for the recreation of the members of the staff were constructed, and a dispensary and hospital in charge of a sub-assistant surgeon were provided.

The meteorological observatory shed was equipped with extra instruments and converted into a second class departmental observatory.

At the present time the chief buildings in Muktesar are:—(1) Main laboratory buildings; (2) The three out-laboratories; (3) Sterilising house; (4) Centrifuge and serum rooms; (5) Serum filling and bottling house; (6) Packing house and carpenters' shop; (7) Bottle washing room; (8) Two cold storage rooms; (9) Grain and oil godowns; (10) Farm manager's office; (11) Power house and work shop; (12) Gas house; (13) Water pumping house; (14) Small animals' house; (15) Three stables to accommodate 25 horses; (16) Dog kennels; (17) Eleven sheds to accommodate 400 cattle; (18) Two post-mortem houses and incinerator; (19) Five operating sheds; (20) Six out-kraals to accommodate 300 cattle; (21) The institute; (22) The dispensary, hospital and segregation ward; (23) Dharmasala and shops; (24) Post and telegraph office; (25) Visitors' bungalow; (26) Public works department inspection bungalow; (27) School for the education of the children of the native staff.

Residences for the permanent staff which in 1912 consisted of:—*Imperial Bacteriologist*.—Major J. D. E. Holmes. *Assistant Bacteriologist*.—Mr. H. E. Cross.

Physiological Chemist.—Dr. P. Hartley. *Head European Laboratory Assistant.*—Mr. M. Kriebel. *2nd European Laboratory Assistant.*—Mr. D. Keiller. *3rd European Laboratory Assistant.*—Mr. G. P. Goffi. *Electrician.*—Mr. P. W. Crowshaw. *Farm Manager.*—Mr. McGinn. Two Senior and two Junior Veterinary Inspectors, Head Clerk, Accountant, Sub-Assistant Surgeon, Artist and Photographer, 2nd Clerk, Munshi, Despatcher and Meteorological Observer, Assistant Engineman, Storekeeper, Librarian, Farm Overseer, Farm Jamadar, Godown Keeper, 1st, 2nd and 3d Native Laboratory Assistants, Compounder, 10 Dressers, 26 Menials, 10 Laboratory Bearers, 2 Packers and Carpenters and 350 coolies and cattlemen.

Muktesar, locally known as Motesar, is situated at the summit of a hill on the inner Himalayas at an elevation varying from 7,500 to 7,702 feet. It is 23 miles by the bridge road North-East of Naini Tal and 13 miles South-East of Almora. The railway terminus Kathgodam is reached by two direct routes; one passing through Dhari, Champi, and Bhim Tal, 24 miles; the other through Ramgarh to Bhim Tal, 21 miles.

The Laboratory estate comprises 7,000 acres, about half of which is covered with oak forest and chir. The Furka, a tributary of the Kosi runs through the estate. Numerous bridge paths have been made connecting the Central Buildings with the out-Kraals situated at distances of 1 to 2 miles from the Laboratory.

The care of the forest and of the cultivation is in the charge of the Farm Manager assisted by the Farm Overseer, two Jemadars, and some 300 to 400 coolies.

A nursery garden is kept up and about 6000 plantings of Deodars, Chir, Walnuts, etc., are made each year.

The Laboratory main buildings. The main building with its accessory buildings is situated at an elevation of 7,500 feet. The Laboratory is two storied and constructed of stone. The whole building is practically fireproof, the roof being of corrugated iron and the floors of stone slabs. The second story rests on iron supports on which are laid iron sheets, covered with cement on which stone slabs are laid.

All the microscope rooms face north. There are three entrances from the south side to the east, west and new wings.

All the rooms are thoroughly equipped with all necessary apparatus and provided with water, gas, and electric light. The walls are lined with glazed tiles, and the floors laid with marble slabs.

The library contains some 3,500 volumes and subscribes to 101 scientific journals.

Out-Laboratories. Each of these consists of two large rooms; one contains incubators and sterilisers, the other is equipped as a microscopic room. All the work connected with serum preparation and investigation in Anthrax, Black-quarter, and Mallein, is carried out in their respective out-laboratories. This prevents the risk of the infection by sporulating organisms and of Glanders being brought into the main laboratory, and tends to the general safety.

The Dispensary and Hospital. The building, situated near the Post Office and Bazaar (native shops) has one ward with eight beds for menial establishment: one with two beds for the subordinate staff. (Attached to each of these wards is a kitchen, bath room, store room, yard, and latrine). An operating room: a dispensing room and store room: a segregation ward for infectious diseases is situated at a distance of about 200 yards from the hospital. It contains four beds and an attendant's room. The quarters of the sub-assistant surgeon are attached to the hospital. The compounder's quarters are separate at a short distance from the main building.

The average number of patients treated daily at the dispensary is 25.

Visitors' Bungalow. The visitors' bungalow was built for the accommodation of officers on training and

officers visiting the laboratory. There are four bedrooms with dressing and bathrooms attached, and a large dining room, all fully furnished. A Khansama is kept at the bungalow and meals are supplied at the usual rates.

The Inspection Bungalow. This bungalow was formerly connected with a Government orchard which is part of the Laboratory estate. It now belongs to the Public Works Department and is used as a residence for the officers of that department when visiting Muktesar on duty.

The Branch Laboratory. The laboratory is situated about four miles outside Bareilly Cantonment on the Budaun road. It was built in 1901 for the purpose of carrying on certain investigations during the winter months of each year. The main building contains two offices, two microscope rooms and a sterilising room. There are five cattle sheds to accommodate about 100 animals, two operating sheds, a post-mortem house and incinerator and a store godown, and quarters for a European Laboratory Assistant and for four other clerks. The Laboratory stands in 30 acres of ground.

Chapter III.—Research work and Publications which occupies over five pages, summarises what has been done in these directions, and indicates the Government and other publications in which the reports have appeared.

THE PRACTICAL APPLICATION OF SERUMS AND VACCINES IN COMBATING INFECTIVE DISEASES OF STOCK IN INDIA

The problem of dealing with infective diseases of animals in India presents many difficulties peculiar to local conditions. In a country like India where measures of treatment, segregation, or of police restriction cannot be imposed in the suppression of epidemics of stock, owing to the prejudices and feelings of the majority of native farmers, and also where the areas to be dealt with are so vast and frequently so difficult, no direct attempt at the total eradication of any endemic infective disease is feasible. Even if it were possible to eradicate a disease from any one province or from the whole of British territory in India it would be impossible to prevent its re-introduction through the frontier line. Consequently, the operations of the Government Veterinary Department are directed towards the suppression of outbreaks of epizootics as they occur, the treatment and protection of individuals being of less consideration and any systematic attempt at total eradication not being attempted.

Even this task of controlling the spread of infection is one of very considerable difficulty, as full and effective measures cannot be put into operation. The Veterinary Service has to rely solely on the aid of serums and vaccines and these can be used only when the owners consent to have their cattle treated. Measures of segregation and disinfection cannot be imposed without the sanction of each individual owner. The scarcity of fuel adds to the difficulty of disposal of infected carcasses.

Glanders, Surra, Lymphangitis Epizootica and Dourine are the only diseases for the control of which legislative measures are in force. At the present time, after practical demonstrations of the benefits of serum injection in outbreaks of Rinderpest, during the past ten years, the use of serum is accepted without opposition in most districts of India. On the part of the Veterinary Service every care has to be exercised that whatever measures are adopted in dealing with an outbreak they shall be free from any danger to the lives of the animals treated, and shall in no way interfere with their work. Serum-therapy has proved to be the safest and most efficient method of operation under such conditions.

Dead vaccines can also be used with safety and confer an immunity of somewhat longer duration than the

serum alone process, but they are less suitable in face of actual outbreak, as the protection induced by them is not established for some days after the injection.

Vaccination by means of living but attenuated organisms is not practised, except against Black-quarter, as a prophylaxis in districts where the disease is seasonally prevalent. The danger of accidents following inoculations, of losses among treated cattle, and of establishing fresh foci of infection precludes this method from general practical use.

For the same reason the method of sero-vaccination which consists of a combined injection of a virus and its anti-serum is not of general practical application in this country.

Rinderpest. In India Rinderpest is the most prevalent and destructive disease of stock. The use of serum has proved of very great value in protecting cattle and in controlling the spread of infection. The immunity following an injection of serum lasts for two or three weeks only, but it has been found both by experiments and in practice that animals which receive an injection of serum and are exposed to actual infection within the period of protection, may contract a mild form of the disease which gives an active immunity of long duration.

Serum not only preserves the lives of the animals treated but it checks the spread of the disease, as the immunised animals are no longer a medium for the existence and transmission of the infection.

Indirectly the use of serum combined with actual exposure to infection by producing an active immunity and thereby increasing the number of immune cattle, is a factor which operates towards the ultimate eradication of the disease. In infective disease of a more sporadic nature, serum operations are less effective and more difficult to apply.

Anthrax. An outbreak of Anthrax spreading among and causing a number of losses among animals in one locality is not of frequent occurrence. In some districts the disease is prevalent during and immediately after the rains. Its appearance in any one locality is intermittent and seldom causes more than a few deaths at each visitation.

Serum affords a temporary protection to individual animals. By two or more injections it is possible to tide the animals over the time during which the disease is prevalent. Where Anthrax appears in an epidemic form among one or more herds or in a stable, the application of serum injections not only affords an immediate protection to all the animals exposed to infection, but it stops short the spread of the disease and gives facilities for carrying out thorough measures of disinfection.

Vaccination against Anthrax cannot be recommended for practice in India. The action of the vaccine is irregular and not infrequently a considerable percentage of deaths result after vaccination, which form fresh foci of infection.

□ Sero-vaccination, which is a combined injection of serum and virus at the same time but on different parts of the body, is attended with less risk than the vaccine and confers a durable immunity. Among a valuable herd of cattle or in a stable where the owner is willing to accept the risk of a few losses, the sero-vaccination method is the most satisfactory method of protecting against anthrax.

Hæmorrhagic Septicæmia. After Rinderpest, Hæmorrhagic Septicæmia accounts for the largest losses among cattle in India. This disease is prevalent throughout the country. Outbreaks generally occur sporadically during and after the rains and seldom assume an epidemic form. In dealing with this disease, serum is used, as in anthrax, to protect animals exposed to infection during the period the disease is prevalent, or until, where possible, measures of disinfection can be carried out and the source of infection removed.

A dead vaccine has been prepared which gives an immunity of about six weeks. This vaccine is of considerable advantage in localities where the disease is seasonally prevalent. Cattle are inoculated and put in a state of protection before the disease has actually appeared among them.

Sero-vaccination is also a safe and efficient method of immunising animals against this disease, but ought not to be practised in areas free from infection and only when owners do not object if a small percentage of loss follows inoculation.

Black-quarter. Charbon symptomatique or Black-quarter is a disease which is more or less confined to certain areas and appears seasonally during the rains, and seldom assumes epidemic form. A serum for this disease has been prepared, but it is not of much practical value as the protection afforded is only of about ten days duration.

Vaccination has proved to be the most satisfactory method of combating this disease. The vaccine is composed of the living but attenuated organisms and confers an active immunity which persists for several months. Vaccination is carried out each year among animals in infected districts immediately before the season when the disease makes its appearance. The vaccine is so attenuated that few accidents are traceable to its use.

Strangles. As India is not to any great extent a horse breeding country, strangles require very little intervention except in the Government Remount Depot. A dead vaccine and a serum has been prepared and has been used with advantage among remounts.

Glanders. Glanders is very prevalent throughout India, and mallein is in all suspected cases used for diagnostic purposes.

Tuberculosis. Tuberculosis is not a common disease of stock in India. Tuberculin is consequently not much in demand.

Tetanus. Tetanus is widespread in the soil, but cases of tetanus in horses are not very numerous and the tetanus antitoxin is only occasionally required.

Surra. A successful method of curing surra in horses by means of arsenic and atoxyl has been worked out, and instructions regarding the doses and methods of administration of arsenic and atoxyl are issued from the laboratory.

The following points should be borne in mind :—

(1) No serum can confer anything more than a temporary protection against its specific disease. The periods for which serums protect vary in different diseases from two weeks to not more than six weeks.

(2) In using serum the object aimed at is not so much the preservation of each animal treated, as the control of the epidemic and the prevention of the spread of the infection.

(3) No serum or vaccine will protect every animal treated. Many individuals cannot be immunised either on account of an intense susceptibility, or more frequently from the existence of an intercurrent disease.

(4) The duration of the immunity afforded by a serum or vaccine is not in every instance exactly the same. Some animals are protected for a shorter time, others for a period longer than the average.

(5) Serum gives an immediate protection. With vaccines the immunity is not established for a few days after the injection. Dead vaccines give a protection for a somewhat longer period than serums. Living vaccines produce an active immunity of long duration (several months to one or two years) but their use is attended with the risk of a small percentage of deaths due to vaccination.

Chapter V. enumerates the serum and vaccines prepared at Muktesar, some details of their preparation and methods of issue, with copies of "instruction" issued with them. It occupies 23 pages. We have

space here only for one section—Anti-Rinderpest Serum. "This serum was first prepared by Kolle and Turner in South Africa, and used there with success in 1898.

The following year it was manufactured at Muktesar and its use introduced into India.

The serum is prepared from cattle which have been first immunised against rinderpest and further treated with one or more injections of virus. The virus is obtained from animals suffering from the disease. Lingard by a large series of experiments extending over three years, worked out an economical method of preparing a serum of high potency.

In the early operations with serum much opposition was experienced from the owners of cattle, who regarded the interference with suspicion and refused to allow their animals to be treated. After a few years, the successful results overcame this opposition, and the demand for this serum increased at such a pace that from 1907 to 1910, the maximum output (of about 500,000 doses) was insufficient to meet the orders for serum. In 1910 improved methods of preparing this serum were discovered, by the application of which in the following year over 1,000,000 doses were manufactured, at the same cost as was previously necessary for half this amount.

The serum was, up to 1910, issued free of cost to the Civil Veterinary Department in each Province, but in this year a charge of two annas per dose was imposed, and surplus serum not required by the Veterinary Department was made available for purchase by Native States and other Governments, etc.

Each brew of serum which consists of from 50,000 to 100,000 doses is carefully tested, and the protective dose for susceptible cattle ascertained per 600 lbs. body weight.

All brews which show potency sufficient to protect, at a dose of 90 c.c., a susceptible animal of 600 lbs. body weight, are issued."

The description concludes with 33 pages of reproductions of photographs—portraits of Dr. Lingard and Major Holmes, and of Senr. Vety. Inspector Khan Sahib Wazir Mohamed, Head Clerk Pundit Krishna Nand, Accountant Rai Sahib Pundit Nitya Nand, Artist and Photographer Babu Duni Chand, 2nd Clerk Pundit Ram Datt—of the main buildings (two of which we reproduce) of Bacteriologists' and Chemists' workrooms, other workrooms and offices, and of several of the many bungalows, out laboratories, sheds, and other addenda which go to make up one of the best equipped and most useful laboratories we possess.

ANNUAL REPORT (1912-13) OF THE BENGAL VETERINARY COLLEGE, INCLUDING THE REPORTS OF THE EPIZOOTIC DISEASES DEPARTMENT IN CALCUTTA AND ITS VICINITY AND THE RAYMOND RESEARCH LABORATORY.

[ABSTRACT].

Major A. Smith, the Principal was posted to Bengal on the 15th April and took over formal charge of the Bengal Veterinary College on the afternoon of the 4th June. He also held, in addition to his own duties, the charge of the Civil Veterinary Department, Bengal, from 22nd April to 27th October inclusive.

Veterinary Instruction. The number of students on the College rolls at the beginning of the session was 107, 99 at the close of the session. They consisted of 72 Hindus, 22 Muhammadans, 3 Christians, and 2 Budhists.

The following table shows the results of the examinations :—

	Opening.	Close.	Examined.	Passed.
Class A	36	29	29	22
" B	30	30	29	23
" C	41	40	40	27
Total	107	99	98	72

Five men from the Supplies and Transport Department were trained in nursing and dressing, and two men from Monghyr, and one from Assam were trained in horse shoeing.

Treatment of Disease. During the year under report 2,428 patients were treated, showing an increase of 244, and 1,892 operations were performed, against 1,881 of last year. The number of cruelty to animal cases sent by the trying Magistrates was 245 which in comparison with 14,932 prosecutions appears very small.

A new hospital for dogs has been erected and certain low portions of the compound of the Bengal Veterinary College have been raised. A new building for the office and quarters for the Principal are highly necessary.

The very willing assistance of the staff has been much appreciated.

EPIZOOTIC DISEASES DEPARTMENT.

The total number of horses admitted into the Contagious Diseases Hospital was 29 including the 2 animals that were under observation at the close of the previous year. Of these, 5 were destroyed for glanders, 1 died from glanders, 1 died from organic complaint, 21 were discharged as free from glanders, and 1 remained under observation.

Rinderpest was prevalent in Calcutta and its Suburbs 1,698 cattle were inoculated with anti-rinderpest serum. A sum of Rs. 522-14 was realised on account of the serum used and credited to Government.

Foot-and-mouth disease also appeared in several parts of the glanders area and also among the bullocks of the Government Transport Lines at Dum Dum and Hastings.

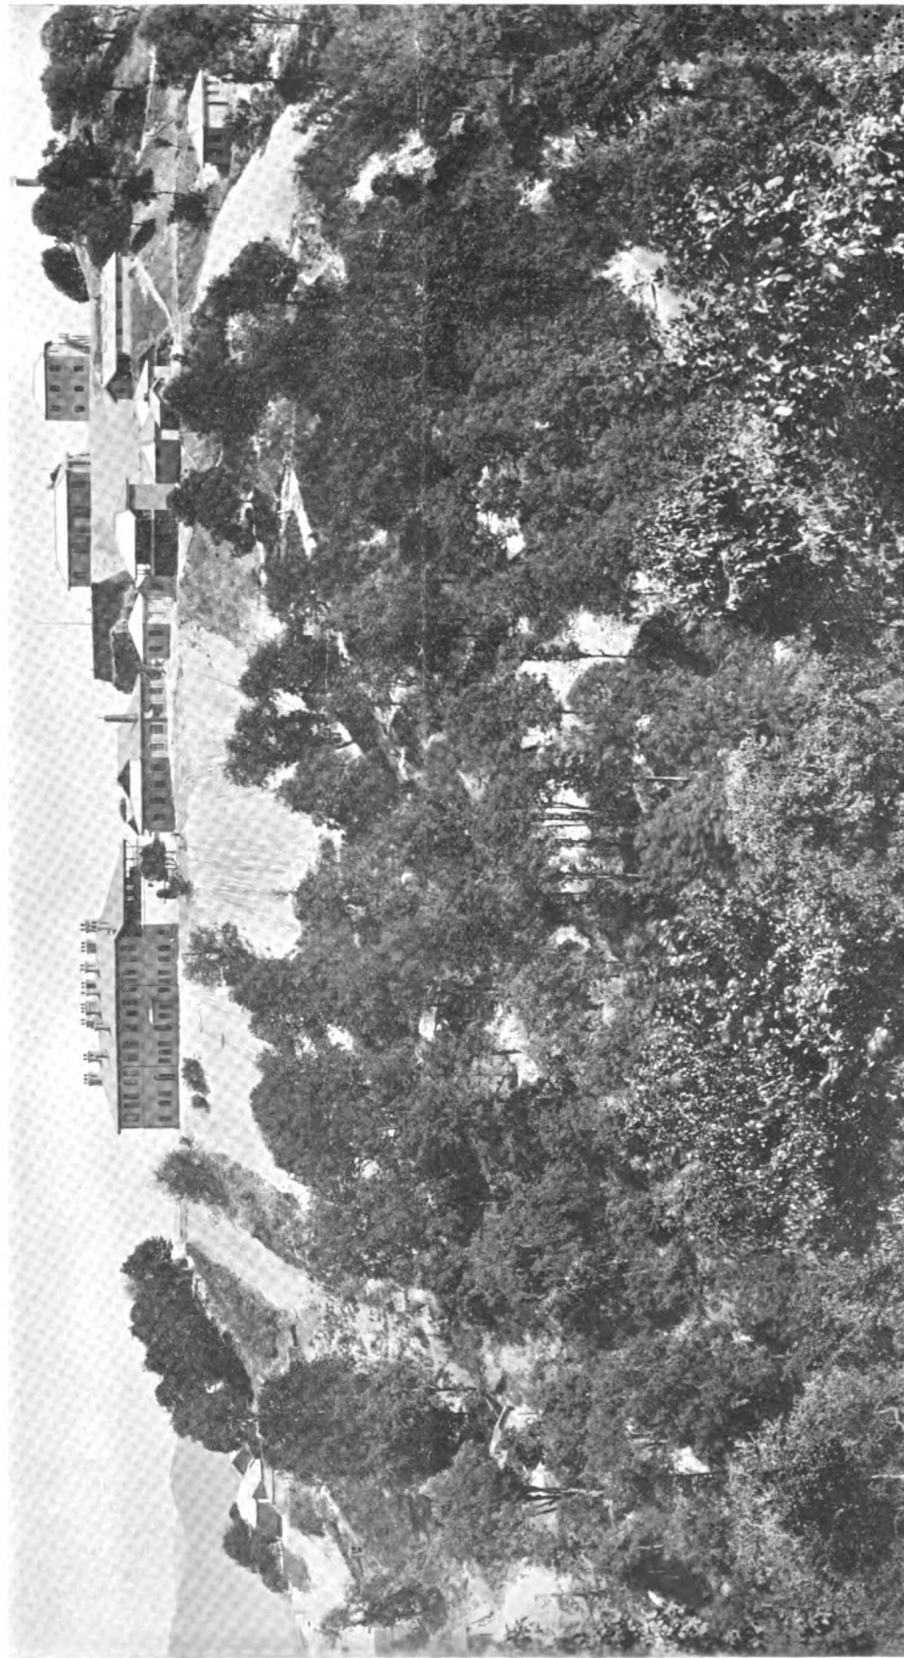

Eighty-four cases of suspected rabies from Calcutta and elsewhere were examined, and sixty of them proved to be suffering from the disease.

RAYMOND RESEARCH LABORATORY.

During the year under report some up-to-date electrical apparatus for special experiments was purchased.

Pathological specimens, smears, dabs, etc., were received from the Civil Veterinary Departments of Bengal, Bihar-Orissa, and Assam, Army Remount Department and other sources which on examination showed among others the causative organisms of anthrax, blackquarter, hemorrhagic septicemia, tuberculosis, piroplasmiasis, trypanosomiasis, filariasis, strangles, rabies, parasitic mange, etc. Autopsies were made on carcasses received from Calcutta and Bengal Police, Zoological Garden, Calcutta Corporation, General Post Office and private persons. The lesions were demonstrated to the senior students. The senior assistant, Mr. S. N. Mitra, had to give expert evidence in many cases. In the course of post-mortem examinations a collection of some interesting parasites has been made which will be sent to Europe shortly for identification.

The British Commission on Foot-and-Mouth Disease and Colonel Sutherland, I.M.S., the serologist, were supplied with a large amount of material for their work. At the request of Dr. Percival Mackie, I.M.S., who has been working under the Indian Research Fund on kala-azar, a large number of spleen smears of dogs were examined with a view to determine their infection by leishmaniasis.

THE IMPERIAL BACTERIOLOGICAL LABORATORY, MUKTESAR, INDIA.
MAIN BUILDING, FROM THE NORTH.

TO VINU
ABSORBIAO

I am glad to report that a cure was effected in a naturally contracted case of equine surra by following the method suggested by the Imperial Bacteriologist. This is the first case of cure reported in Bengal.

CIVIL VETERINARY DEPARTMENT, BENGAL, 1912-13.

[ABSTRACT.]

The necessary changes in consequence of the reconstitution of the territories, though declared in the previous year, practically took effect in the year under report, the completion of which took some time to attain a definite shape so to speak.

I held charge of this department from 28th October, 1912, when on my arrival from Madras I took over from Major A. Smith, F.R.C.V.S., Principal, Bengal Veterinary College. During the period of five months in which I have held charge I was on tour for 61 days, travelled 5,733 miles by rail, 907 by steamer, and 279 by road; inspected 16 veterinary assistants, Kalimpong Homes Farm, and Agriculture Farm, Dacca; provisionally selected seven sites for Dacca new veterinary hospital; and attended two outbreaks of glanders at Burdwan and Barisal.

Contagious Diseases. The numbers of deaths reported of equines and bovines were 373 and 7,637 respectively against 248 and 8,522 of the previous year. The decrease noticed is due, partly to decrease in disease this year, and partly to the correct records kept by the thana officers and their more prompt notification to this department, and consequent earlier attendance of veterinary assistants, though in the latter there is still much to be desired.

In some cases it came to my notice that the police failed to report at all, and in others the disease had subsided before this department got the report.

There were 260 cases of deaths from glanders. Of these, 240 cases occurred at the Sodepur-Pinjrappole alone, and the remainder in six other districts. To avoid difficulties in future, steps are being taken to extend the provisions of the Glanders and Farcy Act throughout the newly constituted Presidency, as was done in the case of the old province of Bengal. Rupees 282 was awarded as compensation for destruction of horses under the Act.

Only ten cases of deaths are reported from anthrax against two of the previous year. At Mymensingh town only, it took something like an epidemic form, causing seven deaths among equines and six among bovines. The diagnosis was confirmed by bacteriological examination, and prompt preventive inoculation was performed, to check the spread of the disease.

There was only one death under the head of surra and dourine. There were 75 deaths from other diseases at the Sodepur-Pinjrappole and 20 at Mymensingh, but no details are available.

The most common contagious diseases in cattle are rinderpest, foot-and-mouth, hæmorrhagic septicæmia, blackquarter and anthrax, and the total number of deaths reported from all these was 7,637 against 8,522 of the previous year.

The decrease noticed is due apparently to the disease being less prevalent in some districts, *i.e.* Mymensingh, Chittagong, Rangpur, and Noakhali.

As usual, foot-and-mouth disease caused a very few deaths, the total number being 433 against 497 of the previous year.

Hæmorrhagic septicæmia broke out rather badly in the districts of Faridpur, Khulna, and Mymensingh, where 146, 348 and 202 animals were reported to have succumbed to it.

Preventive Inoculation. One hundred and forty-six outbreaks of rinderpest, 23 of hæmorrhagic septicæmia,

and three of anthrax at which inoculation could be undertaken were reported, and the total number of cattle inoculated was 21,705, *viz.*, rinderpest 19,113, hæmorrhagic septicæmia 2,407, anthrax 185.

The death-rate among the inoculated was practically nothing, being 46 in all.

In some districts the villages are still opposed to inoculation, and the department has considerable trouble in overcoming their prejudices. In some cases the co-operation of even the literate classes is also unobtainable. It is hoped that every one will take interest in these matters and help the department by reporting outbreaks whenever they occur. Co-operation of the officers of other departments of Government, such as the Co-operative Credit Society, Settlement, Forest and Excise, who are generally required to tour in the villages, is also necessary to deal with outbreaks. They should report to this department the existence of cattle diseases, and impress on the raiyats the benefit of inoculation.

Under the recent orders of Government Rs. 5,251-12 was paid to the Imperial Bacteriologist, Muktesar, on account of the cost of serum supplied to this province during the year. Of this, Rs. 876-12 was recovered from the District Boards in West Bengal, the cost of serum used in East Bengal districts being borne entirely by Government. It is proposed that Government should bear the expense for the whole of the new province.

Veterinary Assistants. During the year there were 37 itinerating veterinary assistants working in the province, and 11 stationary assistants placed in charge of dispensaries who made tours in the districts either at fixed periods or at the time of outbreaks. They visited 10,409 villages and treated 52,705 patients against 8,055 and 52,403 patients respectively of the previous year.

Hospitals and Dispensaries. The number of working hospitals and dispensaries during the year was 18. The dispensaries at Sodepur-Pinjrappole, Howrah and Cooch Behar are managed privately, and the others by local bodies. The total number of patients treated at the dispensaries was 22,106 against 17,289 of the previous year. Of these 4,921 were in and 17,185 out-patients.

BREEDING OPERATION.

The number of stud bulls at present serving in the various districts of the province is 37 the property of the Government, and 26 the property of Local bodies. These bulls are mostly kept by the local bodies at the headquarters station for the use of the town people generally, and by the Jail authorities for the jail cattle only. They are too few in number to be of any appreciable benefit to the public. Applications were received during the year for bulls, but could not be complied with for want of suitable animals.

No part of the province as now constituted is suitable for breeding purposes. The raiyats show very little interest in the selection of bulls, with the result that immature, debilitated and badly shaped animals are generally mated, and that a very large amount of in-breeding takes place.

In spite of our determined and continued efforts, practically very little progress in this direction has been effected. For some years Brahmini bulls from Bihar were supplied. But this practice of depriving certain districts of their good bulls, was not a commendable one and was objected to by the people. In districts in which bulls are stationed the inhabitants make very little use of them, and even when they do so, fail to benefit through ignorance, half-starving the cow and calf. Feeding alone will improve the local cattle considerably, but this point is difficult to drive home, as it

necessitates extra expenditure on the part of the owner with no appreciable result to be seen for a considerable time. The rise of price of agricultural stock is also responsible for a certain amount of deterioration, because people, instead of keeping good calves for bulls, castrate them.

To remedy these, and to really improve the breed, a dairy and breeding farm is being started experimentally in connection with the agricultural farm at Rangpur, and, if it proves a success, it is hoped the plan will be adopted in connection with other agricultural farms.

Horse and pony stallion. There was no horse or pony stallion in the province.

Subordinate Establishment. There were 5 Inspectors and 62 Veterinary assistants at the close of the year against 5 and 59 respectively of the previous year.

Staff Veterinary Assistants. Of the four Staff Veterinary Assistants sanctioned for the province, the services of one were placed under the disposal of the Director of Agriculture, Bengal, in connection with the cattle survey operation. Three only were therefore actually employed by this department. All these men have on the whole worked fairly well and have justified their appointments. I consider staff veterinary assistant a most useful section of the department. It acts as a training and sorting ground for possible inspectors. They are employed on various important duties, especially attending and helping veterinary assistants and inspectors with outbreaks of contagious diseases.

Reserve Veterinary Assistants. There were seven leave reserve originally sanctioned for Bengal. Of these, five were taken to Bihar on the reconstitution of the provinces, leaving two only for the two divisions of West Bengal, and one was received from East Bengal and Assam. These three men were, however, found to be insufficient and disproportionate to the strength of the subordinate staff. Sanction has therefore been obtained during the current year for the appointment of three more men under this head. The work of all the reserve men employed during the year was satisfactory.

Veterinary Assistants. Of the 55 assistants employed, 18 were stationary and 37 itinerant. On the whole the assistants have worked fairly well. I wish they would all take keener interest in their work itself, and that I saw less tendency in some of them to do just enough to escape reprimand.

General remarks. In many districts there is urgent need for the employment of additional veterinary assistants, the number of men already posted being quite inadequate for the amount of work and the large area to be covered. In practically all cases where this is most necessary the district boards have rejected the proposal to post extra men on the ground of lack of funds. There is no scarcity of men, as many more graduates pass out of the Bengal Veterinary College than employment can be found for. Thus it is possible to pick the best men in order of merit and general fitness for the posts vacant.

Cattle poisoning is still a very common practice and the cause of serious loss annually, and it seems practically impossible to detect the culprits. The attention of the district officers has been drawn to this matter.

Breeding and improvement of cattle in this province is particularly bad, and the result of attempts to remedy it most discouraging, owing to the absolute indifference of the owners to the condition of the cattle they have.

The people know literally nothing about breeding, and do not trouble to use the stud bulls where provided, nor feed the cow when often served, nor the calf when born; under such conditions the best cattle would degenerate to the present standard. Better than literature and lectures, perhaps small demonstration farms rearing Bengali cattle will drive home to them the improvement and consequent profit to be made out of

care and feeding of cattle. Until the care of cattle is understood, the purchase and distribution of selected bulls will be productive of little or no result.

P. J. KERR, M.R.C.V.S., I.C.V.D.,
Supt., Civil Vety. Dept., Bengal.

The following notes occur in Resolution—No. 2706 T—R. of the Revenue Department:

In last year's resolution on the work of the Veterinary Department the Governor in Council noticed with satisfaction the excellent results achieved in the Raymond Research Laboratory, and His Excellency is glad to see that steady progress is still being maintained.

The report of the Civil Veterinary Department shows a further considerable decline in the mortality of bovines from contagious diseases. This is attributed to less actual disease and also to better reporting on the part of police officers, whereby the prompt and effective attendance of veterinary assistants was secured. This is satisfactory, but the system of reporting is still far from perfect, and the possibility of improving it has been under the consideration of Government during the year.

The Governor in Council is satisfied that the Director of Agriculture and the officers of the Veterinary Department are giving the vital question of the improvement of cattle breeding the attention it deserves, and His Excellency recognises that progress must inevitably be slow.

The Governor in Council desires to acknowledge his appreciation of the services of Major Smith, the Principal of the College, and of Mr. Kerr, the Superintendent of the Veterinary Department. The opinions expressed by these officers regarding the work of their subordinates have been duly noted.

By order of the Governor in Council,

H. F. SAMMAN,
Offg. Secretary to the Govt. of Bengal.
Darjeeling, 14th Oct., 1913.

Sterilized Milk: Bovine Tuberculosis.

Mr. ROBERT MOND gave an address to a large body of Mid-Cheshire farmers, at Knutsford, on Feb 25th, in the course of which he said:—

"The report of the Inter-Departmental Committee on Physical Deterioration (1904) brought out the fact that the natural food of infants—human milk, was becoming a very scarce and rapidly diminishing commodity. The report continued that in these circumstances it is obvious that the question of the possible alternatives to breast feeding becomes of the greatest importance. They were informed by the highest authorities that modified cows' milk is by far the best.

Two years previous to the appointment of this committee we had started a small temporary hospital with the object of studying the scientific modification of cows' milk so as to provide the individual infant with a food meeting its physiological requirements. Much the best work had been done in this direction by Dr. Rotch, Professor of the Diseases of Children, Harvard University, and we therefore took his work as a starting point.

We had realised the urgent need of a hospital properly equipped for dealing with the treatment of babies suffering from malnutrition, and for the study of the factors involved in nutrition and malnutrition. In September, 1907, we entered into occupation of the Infants Hospital, Vincent Square, which was designed and built to meet the special requirements, and since then we have been able to treat over 15,000 babies. At the same time, under the able direction of Dr. Ralph

Vincent in the Research Laboratory, we have succeeded in largely increasing our knowledge in regard to the chemical and bacteriological changes undergone by milk in the alimentary canal of the infant.

For the last five years the milk for the hospital has been supplied from my own farm. I think it may interest you if I give you a short account of the steps taken to obtain a clean milk for infants.

When I entered in possession of the farm I found two well-built cow-byres, each capable of holding 16 cows, provided with wooden mangers and posts, the tiled roof and resting on hay; rough walls, irregular shaped trusses for holding up the roof and a partly cemented and partly cobbled floor, with no windows or ventilation, except the doors at the ends, and each connected with open yards. They were erected a century ago and were in a good state of repair.

For the production of a reasonably clean article it was essential that the place where the cows were milked should be capable of being kept scrupulously clean, and certainly should not be the place where the cows are housed during the winter months. I therefore decided to cover in the open yard by the cheapest method available, and to use the byres only for feeding and milking. The wood-work of the troughs and posts was replaced by earthenware and sherardized iron. The brick walls were covered with cement. The roof was boarded with match boarding which was coated with a solution of Stockholm tar and turpentine. Windows, ventilation, and a good water supply were provided. As it was found that the cows dragged in straw from the open yards, a cobbled foot scraper, surrounded with semi-circular iron railings, was added, and this prevented the cows from crowding each other when entering the milking shed. When a cow is found to be annoying the others in the open yard she is tied up.

The close relationship between the hospital and the farm enables us to study the effects on the milk supplied to delicate infants of some of the food stuffs given to the cows, and we have found that it is advisable to feed these cows with only from 5 to 10 lbs. of mangels, and that substitutes, like oil cake and brewery grains, must be carefully excluded, as they introduce irritant bodies into the milk, which affect the digestion of the babies. Experiments are still being carried on in this direction.

The milk from each cow is milked into a narrow-top milk-pail with a lid which is sterilised before use. These cans have been carefully adjusted to be all of the same weight, so as to facilitate the weighing of the milk each morning and evening.

The average milk of the morning and evening's milking is daily tested for butter fat, and once a fortnight the milk of each individual cow is tested both in the morning and evening. This enables us to eliminate all those cows which fall short in their total milk production, and we replace any shortage in cows by purchasing heavy milking stock. By this means I was enabled to produce last year about 850 gallons per cow.

As regards the cows themselves, of which I have 30 in milk, I am gradually endeavouring to build up a herd of pedigree dairy shorthorns. My first bull I got from Lord Rothschild's herd at Tring, and I am now using his son from a pedigree cow with Bates strain, and a young bull from the celebrated herd of Mr. Sanday.

Any cow, which for any reason is suspected of being in a bad state of health is removed to one of the isolation wards. These wards were originally oast houses, which are so common in Kent, and they have been altered to meet their present purpose. We find these also suitable for calving.

Before milking, the cows are carefully groomed and the hind quarters and udders are washed in order to prevent stray hairs, dirt and dust falling into the milk.

The whole building, including the roof, is also sprayed. The men wear light overalls and a cap, which are changed and washed twice a week and are sterilised in a steam cupboard before each milking. The men are provided with a changing room (where they put on their white overalls) which is fitted with a hot and cold water supply, so that they can thoroughly clean their hands. They are examined once a week by the doctor so as to ensure that they should have no chapped or sore hands, and that the health of themselves or their family should not be prejudicial to the milk.

The milk is brought to the dairy, which also has cement walls and a match boarded ceiling. The cream separators and the cooling apparatus are so arranged that both ordinary water and brine from the refrigerating plant can be used for chilling the milk. After trying various types of cream separators I have adopted Mey's as the most satisfactory for my purpose.

Opening out of the dairy there is a room constructed of tongued and grooved 2in. timber, in which all vessels, after being properly washed in the dairy, are sterilised under steam pressure, whilst the large valve placed on the top of this chamber, which can be opened from the outside, allows the steam to blow off rapidly, and the vessels inside are left hot and dry.

This chamber I found absolutely essential, as the ordinary cleaning of vessels with hot water, owing to its gradual cooling, fostered the growth of bacilli detrimental to milk as a result of the exposure of these vessels to air.

A small refrigerating plant worked on the carbonic acid principle, supplied by Messrs. West and Benyon, is used for chilling the milk, whilst a Cochrane steam boiler, as used on trawlers, supplies the large volume of high-pressure steam for sterilising purposes.

To facilitate the work of the farm the cooling is done during the afternoon and the milk is stored in a churn, provided with an air wall, which is placed in a refrigerating chamber, so as to be ready to be sent up to the hospital next morning.

To ensure the purity of the milk, samples are sent down to my private laboratory. These samples are taken in sterilised bottles. Directly they are received in the laboratory they are placed in sterilised flasks. These flasks are then placed in the incubator, which is kept at a temperature of 68° F. The most essential point of the incubation is the time that it takes a sample of milk to curdle, and not only to curdle but what is the nature of the curd which has been produced. These are points which are most essential, because many samples may curdle in 48 hours and produce a good curd, whilst others may take 78 hours to produce—and produce what is called a gaseous curd. This we regard as a very bad sample of milk, although it may have taken longer to curdle. By the production of this gaseous curd we at once assume that there was some foreign matter come into the milk through unforeseen circumstances, and on these results obtained we inform the bailliff, and he makes then a minute investigation of the herd after washing and during the time of milking in order to eliminate these defects.

This short description of what has been found necessary to ensure a supply of milk of the highest quality, suitable for delicate infants, ought to make it clear that the necessary alterations and installations are not beyond the means of those of you who obtain the milk of a fair number of cows. In cases where the milk can be delivered within a few hours of milking, say three to four, to the customer, the necessity of cooling is not so great. I have found on referring to the practices of the Copenhagen Milk Supply Company (which is daily supplying some 6000 gallons to the town of Copenhagen, and since its foundation some 24 years ago by Dr. Busck has steadily grown and has adopted practices as

to cooling and feeding similar to those which I have introduced on my farm) that during this period it has succeeded in retailing milk at

10d. per gallon the sealed can,
11½d. " " in bottles for general purposes,
13½d. " " children's milk cooled,
and subsequently

Infant's milk at 16d. per gallon,
besides paying 5% dividend. This proves that with a suitably organised agency the supply of good pure chilled milk is practically attainable.

The score-card for the production of pure milk which has been prepared in the Department of Dairy Industry, College of Agriculture, Cornell University, by Prof. Raymond Pearson, is in extended use in the United States, and I commend this to your attention.

In my opinion, differentiation should be made between milk specially provided for babies and invalids and the ordinary milk of commerce. Where milk is the sole or chief article of consumption it is of the utmost importance that it should be treated with the greatest possible precaution. It is to this type of milk, produced under careful supervision of the board of veterinary and medical advisers, that the term "certified milk" should be applied, and I see no reason why a legitimately higher price should not be charged for this milk, covering the extra expense incurred in its production.

A factor on which I lay the greatest importance is the installation of efficient refrigerating machinery for cooling the milk and keeping it below 40° F. where it is not possible to supply the milk to the customer within a comparatively few hours after milking. At the certified milk farms or at the creameries of the co-operative dairy associations in America, Germany, and Denmark a sufficient stock of natural ice is kept, or a refrigerating plant is installed. Following the valuable suggestion made to me by Prof. Geddes, Edinburgh, I should like to call milk thus treated "chilled milk" to distinguish it from milk which has been insufficiently cooled by ordinary water cooling.

The keeping qualities of milk thus cooled, either at the farm or at a central depot, if it is within easy reach of the farm, are greatly increased, and the fact that milk thus cooled can be stored for several days should balance the inequalities of deliveries and help to pay for the extra expense involved.

Cows' milk as an admirable raw material for the provision of food for babies. You all know that cows' milk changes its composition from the time of calving. These changes are consonant with the requirements of the calf for whose benefit the milk is produced. Similar changes take place in human milk, and the problem of the physician or mother or nurse is how to convert the average cows' milk into that particular type of milk which will best agree with the individual infant. The following table shows the composition of human milk and that of cows' milk:—

	Human	Cow
Fat	4.00	4.00
Milk sugar	7.00	4.50
Whey-proteins	1.00	1.00
Caseinogen	0.50	2.75
Water	87.25	87.00

The excess of curd in cows' milk, and the deficiency of milk sugar are the factors that have to be dealt with. A method was devised in the research laboratory some time ago by Dr. Ralph Vincent which has been extensively used in the out-patient department of the Hospital. It is known as the "fat-whey" method. Milk is treated with Rennet, but all the time the milk is stirred so as to prevent the curd, when it forms, entangling the fat globules within it. The curd is then pressed down to a lump at the bottom of the jug. By this means we have obtained a fluid which contains all the

ingredients of cows' milk except the curd. The "fat-whey" is then heated to 150° F. in order to kill the rennet, and, after it is cooled, a suitable proportion of whole milk is added. The whole milk is not heated at all.

Where you have to deal with very delicate infants, such as those in the hospital, great refinements are required. These are dealt with in the milk laboratory where modifications are provided. For further details I must refer you to Dr. Vincent's "Nutrition of the Infant." By the use of this method the blind fumbling from one inadequate food to another, that so unfortunately prevails to-day, is avoided. Science takes the place of empiricism.

As milk is a very rich food it is not surprising to find that it contains a very large number of bacteria. Some of these reach the milk from the teats; others are introduced by manure, dust, or by water with which the milk may come in contact. For our purpose we can roughly group the bacteria into those which form acid by acting on the milk sugar and those which putrefy the milk by acting on the proteins.

As long as the acid-forming bacteria are active the putrefying bacilli are inert, a fact which has long been made use of in the preservation of boiled foods, such as pickles. All bacteria in milk are destroyed by boiling, but the spores of the putrefactive bacilli are not destroyed. These spores form bacilli again in periods varying from 12 to 24 hours under suitable conditions; but as the acid-forming bacilli do not form spores, they are destroyed and consequently their protective action is lost. The investigations carried out at the Infants Hospital have shown that boiled milk is responsible for the most dangerous forms of infantile diarrhoea.

It is also clear that milk is liable to contamination by specific pathogenic or disease-producing organisms, such as the typhoid and diphtheria bacilli. It appears that the tubercle bacillus is usually not found in milk unless the udder of the cow is tuberculous, and here let me state my conviction that a cow suffering from a diseased udder, whatever the cause of the disease may be, should be absolutely excluded. Her milk should be prohibited as unfit for human consumption. The tuberculin test, however, is a very different thing.

Tubercular infection is, both in cattle and in human beings, extremely common. From a statement in *Le Matin* I learn that at a recent examination in the French Army two-thirds of all the recruits were found to react to the tuberculin test. Pathologists who have had an opportunity of examining thousands of cases find that the number of those who have not contracted the infection at some time of their life is extremely few.

Agricultural statistics have proved that 20 to 25 per cent. of the cattle in the different countries of Europe are reacting at the time of the test. It is only amongst babies that tuberculosis is of rare occurrence, and carefully compiled statistics prove that the number of those contracting the infection steadily increases up to about ten years of age. Tuberculosis is a highly infectious disease, and is chiefly communicable through the breathing organs by the inhalation of tubercular dust. For instance, in the slums of New York they found that three-quarters of all the children in the same flat with a tuberculous patient reacted. Whether bovine tuberculosis is communicable to human beings is a very debatable point. The opportunities of infection are so many and the instances where hundreds of children have for years been fed on milk from tuberculous cows without any marked effect is well known. With a mixed supply the danger of the conveyance of tuberculosis by means of milk must be almost infinitesimal. This has been tacitly acknowledged by all the medical authorities of the world, for none of them advise the boiling of butter.

In connection with the subject, I have attempted within the last two years to study the action of repeated and increased doses of tuberculin on cows which reacted. In two cases where the cows were finally slaughtered the disease was in a very advanced stage, and Mr. Pugh, the veterinary surgeon, considered that the tuberculin had accelerated the progress of the disease. In the rest strikingly beneficial results have been achieved; for the cows are now well, and do not react to the test although they have been frequently tested. But I desire to accumulate further experience before feeling myself justified in drawing definite conclusions from the results obtained. It may interest you to learn that in none of these cows was it possible to find tubercle bacilli in the milk; although in the case of the two cows which were slaughtered there was scarcely an internal organ which was not extensively involved, the udders and their lymphatic glands were perfectly healthy.

In reply to a question Mr. Mond said that in France, out of every 1000, 660 reacted to the tuberculin test, whereas only nine out of every 1000 showed sufficient clinical signs of the disease as to make it worth while to take active steps to segregate them or put them under treatment. In Germany it had been found that of the people in sanatoria 70 per cent. of the cases could be cured. In the case of England the percentage was also a very high one. And he had no doubt that when they got their statistics in a satisfactory manner they would find that the number of cows that reacted to the tuberculin test was very small in relation to those which did not. It might be higher, but he would be surprised if more than five per cent. were suffering from anything which might be decently called tuberculosis. If a cow reacted to the tuberculin test he strongly advised it being watched and put on a strengthened diet so as to fortify it against the disease, and unless emaciation or other unfavourable symptoms supervene, the animal was quite as safe as any they could put their hands on.

Mr. Hailwood asked: Should the milk from an infected animal be sterilised, or put through the refrigerator? Which was the safer?

Mr. Mond said it was impossible for the baby to get a large quantity of the valuable foodstuffs in milk from sterilised milk, and consequently there was bad bone structure and other things, including the condition known as pigeon-chested, undeveloped lungs, and a consequential restriction of the flow of blood; and when the baby, the child, or the grown up walked down the street and received into the lungs a nice piece of tuberculous dust that speedily grew, and then they had the regulation tuberculous patient in the regulation sanatorium under the regulation conditions. The whole thing worked out like clock-work, and consequently his advice was not to sterilise. As evidence of the fact that a tuberculous herd of cattle did not give tuberculosis to those who drank the milk he must refer to the special herd of cattle which provided the richest families in New York with milk, which was drunk in large quantities by the children. When the tuberculin test was applied 45 per cent. of the cattle was found tuberculous and slaughtered. The doctors who had been treating the children formed a committee and carefully examined the hundreds of children who had been having the milk regularly, and of the lot there was only one girl of thirteen who showed signs of tuberculosis, and no one knew where she had got it from.

He would readily admit that if he fed a baby with milk from one or two particular cows, one of which was highly tuberculous, and continually gave the child doses, it might be possible for it to receive the infection. But unless the child had been consistently fed with milk from a cow suffering from tuberculosis of the udder, infection was rare.

In answer to Sir Kenneth Crossley, Mr. Mond said

when he got cows at the dairy show they reacted, but that did not trouble him, and he would have no compunction in sending them to the sale yard.

In reply to Dr. Picton:—He knew of no source in England where he could buy stock which would be eugenically resistant to tuberculosis.

In answer to Mr. Hailwood:—Boiling milk, or even Pasteurising, was responsible for the killing of a large number of babies. Of course they must not give a child cold milk so as to give it a cold, but they could bring it up to the temperature of the human body.

Mr. Speakman: A great many of the things suggested by Mr. Mond could possibly be carried out by the large farmer, but very difficult for the small farmer and the smallholder, and he asked what Mr. Mond suggested to achieve the result.

Mr. Mond suggested co-operation. "In every other country, and in the most outlandish place, the principle of the co-operative system was in practice. In England there were sixteen co-operative credit banks dragging out a most miserable existence. With the co-operative system they could do everything, and without it they could do nothing at all."

Mr. W. Clarkson. They were told to-day that it would be well to have the cows tested every two or three months. When Sir John M'Fadyen was with them he said that if they had their cows tested and found that they were clear of tuberculosis, they would not have a tuberculous cow as long as they lived if they did not introduce one into the stock. He was with Mr. Mond in the opinion that if they had their cows tested tomorrow they would not be sure that they would be free at Christmas.

As to co-operation amongst farmers and smallholders, farmers had to milk twice a day, they had to look after the crops, and had to meet the agents twice a year (Laughter), whether there was co-operation or not. He would like to know how farmers were to manage who got up at five o'clock and had forty cows to milk and to get it to the station, if they had to wash and groom the cows before milking, as suggested by Mr. Mond. Especially when they remembered that Mr. Lloyd George was to introduce a Bill whereby labourers need not commence until seven o'clock. And yet people would want their milk at 7.30.

Mr. J. Sadler would like Mr. Mond to give his opinion as to the milk of a cow which was admittedly tuberculous, but which had not tuberculous udder. Was there any risk or danger either to children or anyone else from the consumption of such milk?

Mr. Mond said that highly tuberculous cows like the two he had killed, and which did not have tuberculous udders, produced perfectly safe milk, but the milk required watching because they did not know when the udder would become tuberculous. Tuberculous udder, except in a few cases, seemed to be the last phase of tuberculosis. As long as the udder was not tuberculous the milk was as good as any other milk.

In response to other questions, Mr. Mond stated that out of the cows which reacted to the tuberculin test there were only about one or two per cent. which really had tuberculosis. The tuberculin reactions did not necessarily mean that the cow was tuberculous.

Mr. Peter Mee inquired if farmers ran the risk of spreading the disease by placing bone manure or bone powder on the land. Mr. Mond said if the bones were boiled there there was no danger as tuberculous bacilli were absolutely destroyed in an excessive temperature.

Mr. Farish asked if it was possible for tuberculosis to be transmitted from the cow to the calf. Mr. Mond urged that tuberculosis was a highly infectious disease and consequently a tuberculous cow was a very great danger to the rest of the stock.

Mr. Burgess asked if a calf could be born with the disease. Mr. Mond said it was unlikely unless there

was present a tuberculous uterus, but a calf might contract the disease in the first three or four hours of life.

The Chairman: Because a cow reacted to the tuberculin test it did not necessarily mean that the cow had the disease. [Mr. Mond: Exactly]. The tuberculin test was not reliable, and always went against the seller.

Horse Failing to Lie in Stall.

In the Perth Sheriff Court, Sheriff Sym has issued his decision in an action by Charles Taylor, coal merchant, Methven, against Alexander Macdonald, Dalquhach, Milnathort, for £15 5s., being loss sustained by the pursuer in respect that on 6th October, 1913, he purchased from the defender at the price of £26 at Macdonald, Fraser and Co's. sale, Perth, a brown horse, seven years old, warranted in all farm work, and free from vice. The said horse, it was averred, was disconform to the warranty and the conditions of sale in respect that it was affected in its wind and failed to lie down in the stall. The horse was sold by consent of both parties at Perth on the 7th November, and realised £13.

The Sheriff in granting absolvitor, with expenses, in favour of the defender, states: The horse which is the subject of this case was sold under this warranty, namely, "Warranted in all farm work and free from vice," and it must be taken along with this fact that the conditions of sale provide "Unless a special warranty is given as to soundness, buyers will be held as satisfying themselves in all respects as to soundness in lithe and limb. This, however, shall not be held as applying to any radical defect in constitution or wind which may not be visible, but which unfits the animals for the purpose for which it is sold." The buyer states that the horse was not according to this warranty in respect, first, that he had a vice. The alleged vice is that he did not lie down in his stable at night, and it is maintained that if a horse bought at this auction does not lie down during the three days which the buyer has in which to give notice, he may be rejected as having a vice. It is often the case that if a horse is of a nervous character, or suffers from any slight illness such as cold, he may not lie down at first in a new place. My view as to this fault of not lying down is just what is expressed in *Elephant on Horses*, on page 96 of the 4th edition. "It occasionally happens that a horse will seldom or never lie down in the stable, but sometimes continues in apparent good health and fitness, and works well; but generally his legs swell, or he becomes fatigued sooner than other horses. It is a bad habit, and one decidedly injurious to his health, and so tending to impair his usefulness. It is a vice." It is very difficult to apply this to a three days' warranty. I think the truth about this horse is that he does lie down, but that for a time about the time of the sale he did not lie down in his new surroundings when he had a cold and was put to a kind of work which involved a great deal of strain. The chief difficulty I have had on this point is that after he was sent to the mart of Macdonald and Fraser he did not lie down for some time. On the whole I cannot affirm that he can be rejected for a vice, and I notice that there is no evidence at all that he suffers in appearance or health from not lying down for a time. The other matter refers to the horse's wind. I think if he had been warranted sound that I could not have said that he was a sound horse at the time of sale because there was a temporary unsoundness at all events from cold. He ought to have been returned. That, however, is not the question. It is stated he suffered from a radical defect in wind, not visible, but unfitting him for the purpose for which he was sold. I do not doubt that his wind was affected at the time he

was examined by Mr. Reynard and a man from Macdonald and Fraser, but I attribute that to the cold which the pursuer's man says that he had somewhat severely when in the pursuer's stable. He is not a roarer, and I scarcely see how that comes into the case. If there be some affection of wind which could not be readily observed at the time of sale, I think it must be very slight, for there is much evidence entirely favourable in his health in all respects. I cannot affirm that this horse does not come up to the warranty which I have quoted. In this view it becomes unnecessary to consider the defence that this horse was retained by the pursuer and worked after he had been definitely rejected. Pursuer's agent explained his summons on this head, and I assume that he did so successfully but give no opinion upon it. The first day's ploughing work that the horse did for the pursuer was certainly after he had rejected him, and I think his conduct in this respect was not prudent, but I do not require to decide on this view of the case. On the pursuer's side the case seemed to me quite honest, and his statement of his fault to the horse quite moderately put, but it is a horse which I think might be sold again with the warranty which he has, unless some change has passed upon him since.—N.B.A.

Meat Inspection.

For years past there has been widespread dissatisfaction with the methods of inspection of meat. It has been frequently complained that many of the inspectors have not the necessary qualifications and experience, that different standards are applied by the inspectors under the different local authorities, and that frequently meat which should be condemned is allowed to be sold, while much meat is condemned which, if properly cooked, is quite wholesome. In the result producers and consumers alike sustain loss. The Scottish Chamber of Agriculture and other agricultural bodies have repeatedly urged that the Local Government Board should take steps to improve matters, and especially that they should insist on a proper and more or less uniform system of inspection by competent officials. Though tardily, the Local Government Board are showing signs of awakening to the requirements of the matter. The first symptom of this was the recent appointment of Dr. Leighton as a Veterinary Medical Inspector to their staff, followed by their instruction to him to "conduct a full inquiry into the question of establishing a uniform system of standard of meat inspection for Scotland, and to present a report thereon." They have now invited the Scottish Chamber and other bodies to submit their views on the question, which we learn is likely to be done.

The Association of Veterinary Officers of Health have, however, indicated that it would be more satisfactory that a Commission consisting of Dr. Leighton, as representing the Local Government Board and the medical profession, a representative of the consumer, the butcher, the stockowner, and the veterinary profession should be appointed to make the proposed inquiry. It is more likely, however, that these separate interests will be invited to submit evidence.—*Scotsman*.

The Board of Control of Toronto announce that a plebiscite may be taken upon the question: "Are you in favour of the City engaging in the dead meat trade to supply retailers, and of raising 200,000 by an issue of debentures to carry on this business?" If the project should be favoured by the people, it is understood that the city will kill live stock at the new civic abattoir, and endeavour to compete with the private companies who now supply retailers.

Plant Diseases—National Inspectors.

Speaking at the annual dinner of the Kent Farmers' Union at Maidstone, on Saturday night, 14th inst., Sir Sydney Olivier, Permanent Secretary of the Board of Agriculture, made a definite statement as to the policy the Board had decided to pursue in future under the Diseases of Plants and Pests Act. He said the system of having merely county inspectors was not satisfactory.

It was proposed to strengthen the Board's inspectorate and deal with plant diseases in the same way as they dealt with diseases of animals. Probably twenty or thirty additional inspectors would be appointed in the course of the next year to cope with and stamp out outbreaks of plant disease wherever they might occur. This would be done without expense to the counties. —*Daily Telegraph.*

Medical Research under Insurance Act.

A Medical Research Committee to administer the funds made available under the National Insurance Act for the purposes of research has been constituted. Amongst the first members of the new body we note the name of Dr. William Bulloch, Bacteriologist to the London Hospital, and Professor of Bacteriology in the University of London.

An Advisory Council of Research is also constituted which includes the names of Dr. Sheridan Delépine, Sir John M'Fadyean, Sir Stewart Stockman, and Dr. G. Sims Woodhead.

It is laid down that the Medical Research Committee shall from time to time prepare schemes for research,

including, if they think fit, schemes for inquiries and the collection and publication of information and statistics, and shall submit such schemes to the Chairman of the National Health Insurance Joint Committee for his approval. Before approving any scheme so submitted to him, the Chairman of the Joint Committee will consult the Advisory Council for Research.

Members of the Research Committee are to hold office for three years.

Foot-and-Mouth Disease.

The Irish Department of Agriculture on Sunday last issued a notice stating that three outbreaks of foot-and-mouth disease have been discovered in the County Cork—at Ballynacourty, near Kinsale, at Douglas, and at Ballynacrusa, near Queenstown. The Department has made the usual orders regarding the movements of stock in these districts.

The Cattle Market at Liverpool was closed on Monday owing to the outbreak of foot-and-mouth disease in two districts in that city. In an Everton shippin five out of ten animals were affected, while a considerable number of a herd of upwards of twenty cows in a Walton shippin were also discovered to be suffering.

Two suspected cases of foot-and-mouth disease are reported from Toghher and Ballygarvan, both in Cork rural district, and quite near that city. All the infected areas are now patrolled by police. Owing to the closing down order the food supply of the city is seriously

threatened, and it was estimated that the quantity of meat at the disposal of the butchers would not last over Wednesday.

The existence of foot-and-mouth disease was confirmed on Wednesday, 4th inst., on premises near Conway, Carnarvonshire.

R.V.C., London v. R.V.C., Dublin.

This annual Rugby match between the colleges was played at Ballsbridge, Dublin, on Saturday, Feb. 21. After a close game London won by three points to nil—a penalty goal kicked by Bennett in the first half. Considerable interest was shown in this match, as the colleges were playing for a cup presented by Professor and Mrs. Wooldridge of London. Last year (the first of the competition) the match resulted in a draw, so that the London College is the first to possess the cup. The match was refereed by Mr. Louis Magee the famous Irish International. On Saturday evening the teams were entertained at a dinner at the Gresham Hotel and after that went to the Theatre Royal.

The following played for the respective teams:—

R.V.C. London.—Full-back: L. P. Pugh; Three-quarters: S. C. Bennett, G. Barnett, H. D. Neave, L. Jeffrey; Half-backs: W. Gibson, J. Coleman; Forwards: G. H. Melck (captain), W. A. Macgregor, H. B. Williams, J. Barlow, E. C. Bowes, H. Edwards, E. V. Hunt, D. E. McRae.

R.V.C. Dublin.—Full-back: T. O'Brien (captain); Three-quarters: T. F. Donworth, Morris, Peatt, Doyle; Half-backs: J. Bell, E. M. Elligott; Forwards: L. Hilliard, J. Malone, C. Ryan, Mettam, Fennelly, Cunningham, Barry.

Personal.

GOLDING.—On Feb. 23rd at Old Cross, Hertford, the wife of Walter W. Golding, M.R.C.V.S., of a daughter.

MR. R. J. HICKES, F.R.C.V.S., Market Weighton, Yorkshire, has been appointed a Justice of the Peace for the East Riding of Yorkshire.

Prof. J. PENBERTHY, Newnham; Messrs. F. AULTON, Tutbury; W. J. HATTON, Richmond; R. RIMMER, Kendall; and H. H. TRUMAN, March, acted as Veterinary Inspectors at the 35th Annual Shire Horse Show held recently in London.

Dr. R. T. LEIPER, Helminthologist of the London School of Tropical Medicine and Wandsworth Scholar, has left London for the East, with Surgeon E. L. Atkinson, R.N., and Mr. Cherry-Garrard, both of whom accompanied the Antarctic Expedition. The object of the expedition is to ascertain the mode of spread of trematode diseases of man, especially bilharziasis; investigations will also be made into ankylostomiasis. Dr. Leiper, it will be remembered, contributed a paper at the Carnarvon meeting of the N.V.A. and quite recently an address with lantern demonstration at a meeting of the Central Society.

Prior to the discovery of Australia 130 years ago the British farmer had very little experience with the production of fine wools. In Australia, however, he found a soil and climate more suitable for the Spanish Merino than for the British Mutton breeds to which he had been accustomed in the United Kingdom. He introduced Spanish Merino to the Australian pastures, and by practical breeding he has in the course of a century built up not only the greatest flock of sheep possessed by any one country, but a flock which produces a fleece which tops the wool markets of the world. Australian wool is without equal anywhere.

ARMY VETERINARY SERVICE.

INDIAN CIVIL VETERINARY DEPARTMENT.

Major A. S. Trydell. Dated Jan. 30.

OBITUARY

H. W. LEECH, M.R.C.V.S., Worthing.

Graduated, Lond: May, 1891.

DAVID R. SOWERBY, M.R.C.V.S., Anlaby Road, Hull.

Edin: April, 1871

Mr. Sowerby died on Feb. 26th, from diabetes. Aged 67 years.

GILBERT BONE, V.S., (retired) died on Feb. 15th, at 5 Market Street, Alton, Hants., from cardiac disease with bronchitis, at the age of 76 years.

Mrs. GAMGEE, widow of Professor John Gamgee, M.R.C.V.S., of Edinburgh, died on Thursday, February 19th, in her 90th year at Brook House, North Stoke, Wallingford, Berks. the residence of her nephew, Mr. Harold Hartley, in whose home she had passed the declining years of her life.

She was the daughter of Captain T. Hartley, 23rd Royal Welsh Fusiliers, who served under Wellington during his Irish administration, and afterwards went through the Peninsular War under him. Captain Hartley was severely wounded at Badajoz and was subsequently invalided home. Professor Gamgee was the well-known authority on veterinary matters and cattle plagues. It was largely through his exertions that the great plague, both here and in the United States in the 'seventies, was stamped out. Mrs. Gamgee accompanied him during his travels and had many stories to tell of adventures in the West 40 years ago. She retained her faculties almost to the last.—*The Times*.

PARNELL.—On February 27th, at 15, Cromartie Road, Hornsey Rise, N., Catherine Victoria Parnell, widow of the late Charles Parnell, M.R.C.V.S., aged 83 years.

TWO PRE-ASEPTIC LAPAROTOMIES.

Dear Sir,

I was much interested with Professor Reynolds' lecture at Grantham on Hernia in the Dog, and his description of the antiseptic and aseptic methods of operation with a great number of details which I think will be very difficult to remember at the time. Certainly I think the aseptic method of operation is the best, but how seldom can that be carried out in a country practice.

I will here describe, for the amusement, and I also hope for the benefit of one or more of your numerous readers, how I operated on two cases of scrotal hernia—a Clydesdale colt and Clydesdale foal.

The colt was foaled with scrotal hernia of the near side; this got very large, and I was called in by the owner to try and reduce it. I threw the animal, then a few weeks old, manipulated the part and got the bowel nicely back into the abdomen, then I gathered the loose skin tightly up, put a skewer—not aseptic—through it, and tied a strong piece of string on the upper side of the skewer sufficient to stop circulation in the dependant skin. In about a fortnight the dead skin came off, and the colt looked much better for a little while; but gradually the skin stretched and the hernia was soon as bad as ever, so I tried the same method again, but without success. The owner, a farmer, then became tired of the colt; he did not like to see him although he cost ten guineas to get. He asked me if I would have him as a gift as he was determined to keep him no longer. I said "Certainly," and thanked him for the handsome present. I sent him to my brother's farm. In a short while the hernia became strangulated and the poor animal rolled about in agony all night; I was sent for, as they said the colt had colic. When I saw what was the matter I had the colt thrown and worked the part well with my hands, and got it nicely reduced. I decided then to operate somewhat after the manner of Professor Reynolds. I had mentioned the case to the late Mr. Chivas, of Corbridge, who asked me to let him come whenever I operated upon him, so I wrote to him, and arranged to have it done at once. I took him out to the farm, we threw the colt, Mr. Chivas chloroformed him (not with proper muzzle, for I am speaking now of 25 years ago). I first castrated the colt, then reduced the hernia, scraped the edges where the bowel came through, and was going to suture him up when my friend said, "Hunter, I have never had my hand in a living horse's inside like you have, let me put my hand inside of him." I said, "double up your shirt sleeves and wash your hand and arm in this antiseptic fluid, and you shall." He did so, and after putting his hand well in and over the bowels he said "Now, Hunter, he'll die." "Well," I said, "you are consoling."

I finished the operation, and in a short while he came out of the chloroform and was steadied into his box. My brother went to look at him before he went to bed, and in going round him the colt let out, but fortunately missed my brother, who told me about it next morning when I went to see the colt. I said, "after that Mr. Chivas will be wrong, and he won't die," and sure enough he made a first class recovery, and I sold him to a client 18 months after, for whom he did well.

My next attempt to operate was on the foal. The farmer sent for me in a hurry, saying his foal, five days old, was very ill, so I went at once and saw it was a matter of life or death. I got a little clean warm water and poured a little carbolic acid amongst it, had the foal turned on to his back and held by two men, but gave no anæsthetic. I castrated the foal—he was the youngest I ever did castrate—returned the bowel, and sutured up the inguinal opening, and finished with a stitch or two in the scrotum. The poor thing was lifted on to its legs and made an uneventful recovery. This animal was sold when 2½ years old on Newcastle Cow Hill Fair for £50.

So you see it is not always essential to be aseptic, but I do say come as near to it as you can.—Yours truly,

WM. HUNTER.

Newcastle-upon-Tyne.

A CORRECTION.

On page 561 of last week's issue I am reported as having made a remark, the meaning of which is unintelligible. The remark I did make was, "If veterinary surgeons had more generally joined local associations in the past, then there would have been less need for forming separate veterinary inspectors associations, as work necessary to be done by them could have been done through the local associations."—Yours faithfully,

E. BRAYLEY REYNOLDS.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1340.

MARCH 14, 1914

VOL. XXVI.

ASEPSIS.

Recently there has been a little discussion upon asepsis, and the difficulties of obtaining it in veterinary practice. Undoubtedly the difficulties are great, and often insurmountable. On the other hand, every experienced practitioner knows that numberless serious operations have been performed under conditions which were anything but aseptic. Perhaps the recognition of these two truths accounted for much of the total indifference to asepsis that was very common amongst veterinary surgeons for many years. Perhaps even to-day the same recognition may lead some men to forget the golden rule of "Be aseptic when you can," when they might advantageously observe it.

Medical men know quite well that, even in human surgery, it is often impossible to ensure complete asepsis when operating in a general practice. This applies much more forcibly to veterinary operations, especially to emergency ones. But a medical man, though often working under far from ideal conditions, nevertheless frequently obtains perfect results. And similarly a veterinary surgeon, even more unfavourably placed, may do a great deal to minimise sepsis by observing a few simple rules.

The advantages of anaesthesia from the point of view of asepsis are obvious, as are also those of the modern methods of skin sterilisation with iodine or petrol. Of course, the operator ought to touch nothing that has not been sterilised, and all clinicians know that it is often impossible to keep to this rule in our work, but the regular immersion of the hands in a disinfectant after contamination will generally avert sepsis. Every practitioner knows these rules, but the difficulty is to observe them on many occasions in practice. When consciously operating under unfavourable conditions, a man is apt to think it useless to try to follow the Listerian precepts. But by sedulously keeping them in mind he may really succeed, under most conditions, in performing a wonderfully close approximation to an aseptic operation.

The advance of surgical and bacteriological knowledge has taught us that bacterial contamination during an operation is only possibly and not necessarily harmful, and it has simplified the technique of our asepsis. The first lesson should encourage us to operate, even under adverse circumstances, and the simplified technique helps us towards the aseptic ideal.

PRELIMINARY REPORT OF THE ETIOLOGY OF CAT INFLUENZA.

By J. BASIL BUXTON, F.R.C.V.S., D.V.H., Veterinary Superintendent, Wellcome Physiological Research Laboratories, Herne Hill, London, S.E.

The object of this note is to characterise an organism which I believe to be hitherto undescribed, which is obtainable from cats suffering from influenza, and appears to have a causal relation to this condition.

Clinicians have on several occasions called attention to the fact that there exists among cats a disease which, while resembling the respiratory form of "distemper" in some respects, yet shows certain pathological differences, and always presents a definite chain of symptoms. This disease has received the name of "Cat Influenza"; probably because its characteristic is a respiratory catarrh. It has been noticed particularly among animals that have returned from shows, those which have been purchased from dealers, and with special frequency among cats, especially the more delicate breeds, which are kept in numbers together in a warm moist atmosphere, particularly if the ventilation is insufficient. Its occurrence among animals living in the open is extremely uncommon. My attention was first directed to this disease by observing that the majority of cats at these laboratories, if kept for any length of time in the common cat-house developed it. The incubation period appears to be usually from ten to fourteen days, and apparently one attack confers but slight immunity. Adult cats may, and frequently do, suffer from as virulent an attack as kittens when brought into an area of infection.

The onset is usually mild in character, and the animal only has periodic sneezing attacks. There is at this stage no nasal or conjunctival discharge. In old cats, and those which have suffered from a previous attack, the infection may end here, or subsequent to this the animal may have a slimy discharge from the mouth, a common indication of sore throat, and show great difficulty in swallowing. All food is refused for from four days to a week, and then there is apparently a sudden and complete recovery. In young animals, and those suffering from a more virulent attack, on the third day from the onset of the sneezing there is a watery discharge from the eyes and marked photophobia, the discharge later becoming muco-purulent. At about this time there is also a profuse nasal discharge of a similar character, great difficulty in swallowing, and all food, even milk, is refused. Usually this condition persists for several days, and

is followed by resolution if the animal's strength can be maintained. In some cases, however, the infection extends, involves the pulmonary parenchyma, and death takes place in from 24 to 48 hours after the first signs of pneumonia. I have been fortunate in having at my disposal an almost continuous epidemic, so that the disease was seen in all ages and stages. It is extremely uncommon to find animals affected with influenza suffering from diarrhoea—there seems, indeed, to be a tendency towards constipation.

On post-mortem examination the lesions are found to be confined entirely to the respiratory tract. There is marked injection of the mucous membrane of the pharynx, larynx, and trachea with an abundant secretion of viscid, and sometimes frothy mucus. When the lungs are affected there is a typical croupous pneumonia.

In the early stages of the disease I was able in almost every case to isolate in pure culture from the smaller bronchi, and frequently from the trachea or organism of which the characteristics are given below, and which, so far as I have been able to ascertain, has not been previously described. In the later stages this is rarely possible. When the lungs are involved the organism can invariably be recovered from that situation in pure culture. In advanced cases also the organism can be recovered from the heart blood. The serum of cats suffering from this disease has been examined for agglutinating and complement binding properties with this organism, and has always shown a higher agglutinating and complement binding titre than has that from apparently healthy cats used as controls.

It seems probable that the discharge from the eyes and nose in the later stages owes its mucopurulent character to secondary organisms, because after the onset of these symptoms it is practically impossible to recover the organism from the upper air passages in pure culture.

MORPHOLOGY OF THE ORGANISM ISOLATED FROM CASES OF CAT INFLUENZA.

A short bacillus from 1.5 microns to 2.5 microns in length and about .3 of a micron in breadth, rarely found in chains except in artificial media, when they are not composed of more than three or four elements. It shows marked brownian movement, but is not progressively motile, and is aerobic in habit.

STAINING REACTIONS.

The organism does not stain readily with the ordinary aniline dyes but best with Kühne's methylene blue or fuchsin.

CULTURAL CHARACTERS.

Plain agar stroke. In 24 hours at 37° C. there is a moderate growth which is raised, with a moist surface and almost colourless. After 48 hours the growth tends to spread and is greyish-white in colour, and shows a faint yellow tinge at the margin. This yellow colouration becomes more marked in older cultures, and is characteristic of the organism.

Blood agar stroke. The growth is similar in appearance to that on ordinary agar, but shows a greater tendency to the yellow colouration.

Potato. After 24 hours at 37° C. the growth is very meagre and scarcely visible. In 72 hours it is fairly well marked and shows a faint yellow colour.

Gelatin stroke resembles the growth on agar.

Gelatin stab. Growth takes place at the surface and about half of the way down the needle track, but does not show any peculiar character and the gelatin is not liquefied.

Broth. After 24 hours there is a moderate turbidity. After 48 hours a rich growth and some sediment in the bottom of the tube. There is no odour.

Milk is not usually coagulated at the end of 24 hours, two strains, however, show a slight coagulation after from 36 to 48 hours.

EXPERIMENTAL INFECTION.

It has been found possible to transmit the disease to healthy cats experimentally with a pure culture of this organism—a typical result being obtained by injecting a suspension in saline into the nostrils.

A further communication concerning experimental infection, protection and serum diagnosis will be made at a later date.

EASTERN COUNTIES VETERINARY MEDICAL SOCIETY. [NATIONAL V.M.A.—SOUTHERN BRANCH].

The annual meeting was held on February 24th, at the Bell Hotel, Norwich. Mr. W. L. Little, Yarmouth, a vice-president, was voted to the chair in the absence of the President (Mr. F. B. O. Taylor) who has left the district for Stratford-on-Avon. Present: Prof. G. H. Wooldridge, London; Messrs. W. Shipley, D. S. Jack, H. F. Downe, F. Morton Wallis, W. Waters, Sydney Smith, sen., A. McTurk, G. McIntyre, A. C. Holl, M. Bray, H. Buckingham, J. Robertson, H. V. Low, and Sidney Smith, jun., hon. sec. and treas.

Letters regretting absence were received from Sir John McFadyean, Messrs. H. P. Standley, N. Almond, F. T. G. Hobday, A. H. Santy, F. L. Gooch, E. H. Leach, J. E. Kitchin, J. Hammond, T. G. Heatley, P. Turner, H. E. Wilkinson, J. F. Thurston, J. K. Gooch, A. Holl, E. Margaron, W. E. Livock, J. Cleveland, W. J. Browning, W. Turtill, C. C. Nesling, T. Love, J. Bee, A. F. Castle, T. J. Faithfull, and Captain Bone, A.V.C.

The minutes of the last meeting were taken as read on the proposition of Mr. Shipley.

NEW MEMBER.

Mr. BAXTER, Downham Market, who had been proposed and seconded at a meeting of the Committee, was elected.

Correspondence.—The HON. SEC. reported an acknowledgment from Mrs. W. M. Reeman of the wreath sent by the Society, and a letter from Mr. F. B. O. Taylor thanking the members for their good wishes on his new venture, and saying how glad he had been to do what he could for the Society as its hon. sec. for a few years.

SECRETARY'S REPORT.

The HON. SEC., in his third annual report, said that again they had been rather unfortunate in the matter of a

President, as Mr. Taylor, very shortly after he was elected, left the district. It was a notable fact that the members had been entirely responsible for the papers and discussions at the meetings. Mr. Shipley introduced "Parasitic Mange," Mr. Castle read a paper on "Sterility in the Mare," and Mr. Waters read an interesting paper on "A Few Cases." Two new members had been elected, but unfortunately two prominent members—Mr. W. M. Reeman and Mr. W. Bower—both of whom had held the office of President, had died. The balance sheet was a favourable one, although a second donation of ten guineas to the International Veterinary Congress was made, also five guineas to the Victoria Veterinary Benevolent Fund. The balance in hand was £20 19s. 6d., compared with £22 13s. 1d. last year. One subscription was outstanding, and half-a-dozen letters had failed to evoke any reply. There had been a good demand for the Society's instruments, especially for the new tooth cutters, which had been out 15 times, the sandcrack instruments twice, and the écraseur and Robinson's tooth forceps once each. As he was resigning, he took that opportunity to thank all the members for the support they had given him during the three years he had held the office of secretary. He did not regret the time given to the work, but he thought he had done his share, and it was time for someone else to take on the work.

Mr. WALLIS proposed the adoption of the report and balance-sheet. Mr. Robertson seconded, and this was agreed to.

ELECTION OF OFFICERS.

President.—The Hon. Sec. said the Committee unanimously recommended that Mr. W. L. Little be asked to accept the presidency for the coming year. Mr. Waters proposed, and Mr. Smith, sen., seconded, and this was carried.

Mr. LITTLE said he realised that the president accepted some responsibility, and he could not have taken the office unless he felt he had the support, individual and collective, of all the members. He hoped they would resolve to unite to make a success of the Society. There were several ways in which they could help. There were members of the profession living in the district who were not members of the Society. They should be button-holed and brought to our meetings. Then they would not be long before they made up their minds to join. They could help the Secretary by taking notice of his requests—often quite easy to forget. In making him head of their Society they had honoured him in such a manner that he did not know how they could honour him more, and he thanked them for it most heartily.

Vice-presidents.—Messrs. T. E. BARCHAM, J. BARR, E. A. HUDSON were proposed by Mr. Shipley. Mr. Waters seconded and this was carried.

Auditors.—Messrs. W. SHIPLEY and T. G. HEATLEY. Proposed by Mr. Robertson and carried.

Hon. Sec. and Treas.—Mr. A. C. HOLL. Proposed by Mr. S. Smith, jun., seconded by Mr. W. Shipley, and carried.

Committee.—The Committee was re-elected except that Mr. Sidney Smith, jun., will take the place of Mr. J. Barr, the other members being Messrs. Sidney Smith, sen., T. E. Auger, J. K. Gooch, H. P. Standley, H. Low and W. Waters.

The Instruments.—Mr. SIDNEY SMITH, JUN., said he would be willing to take charge still of the instruments as he was conveniently situated as to trains, and it might assist the new secretary, who lived in the country. The suggestion was approved.

Mr. SHIPLEY moved that one pound be given to Mr. Smith's man for keeping the instruments clean and in order, as they were always sent out well, and it meant a certain amount of trouble.

Mr. WATERS seconded, and this was agreed to. Mr. SMITH, on behalf of his man, expressed his thanks.

THE NATIONAL VETERINARY ASSOCIATION.

Mr. SHIPLEY proposed that the affiliation fee of one shilling per member be sent to the National Veterinary Association. Mr. Robertson seconded, and this having been carried it was resolved that Messrs. M. Wallis, S. Smith, jun., and the new Hon. Sec. be the Society's representatives on the Council of the N.V.A.

V.V.B. Fund.—Mr. WALLIS proposed that 5 guineas again be given to the Victoria Veterinary Benevolent Fund. Mr. Buckingham seconded, and this was agreed.

Royal Sanitary Institute.—The question of sending a delegate to the Blackpool Congress in July was referred to the Committee on the motion of Mr. Shipley, seconded by Mr. Morton Wallis.

HUNTING FUND.

The Hon. Sec. read a circular with reference to a memorial to the late Mr. William Hunting, and reminded the meeting he was an honorary associate of the Society. He moved they show their sympathy by subscribing five guineas. Mr. Shipley seconded, and this was agreed to.

COUNCIL ELECTION.

The Hon. Sec. said Mr. Shipley came up for election again this year owing to his being drawn in the ballot to take the place of a deceased member. He moved that the Society nominate Mr. Shipley as candidate, and give him their support.

Mr. WALLIS seconded, and said he hoped everyone would do their utmost to support Mr. Shipley.

Mr. SHIPLEY said he would be glad to have their help as he did not like to go in for a thing and then be kicked out unless anyone thought it was time for him to go.

The motion was unanimously adopted.

Summer Meeting.—Mr. WALLIS proposed that the next meeting be held at Colchester, and he hoped Norfolk and Suffolk members would make an effort to attend. Mr. Shipley seconded, and this was carried.

POST-MORTEM SPECIMENS.

Mr. WATERS presented a large thrombus or clot he removed from a three-year-old cart filly affected with sclerostoma. During life this filly showed every symptom of thrombosis, but though he examined carefully per rectum, he was unable to demonstrate anything. He made a post-mortem and found this thrombus in the anterior division of the mesenteric artery. It was interesting owing to its position, being the one place where it could not be demonstrated during life. This filly starved herself to death, and had probably been ailing for three or four months. All the other arteries were perfectly healthy.

Mr. Waters also brought a wild rabbit's skull which had extraordinary teeth, the result probably of the incisor teeth not meeting one another during life. This rabbit had also broken a hind leg, which set in a false joint at the hock, and despite all its afflictions when caught on his brother's farm, was in good order.

Prof. WOOLDRIDGE said the thrombus specimen was quite an unusual one on account of its enormous size, the largest in his experience. It was usually found in the anterior mesenteric artery.

The Professor then exhibited the largest bladder calculus he had ever seen, taken from a retriever on post-mortem. He never saw the dog during life. The calculus, he believed, weighed about 12 ounces.

Next he showed two specimens of navicular bones which he thought might be of interest. He had previously shown one specimen at the meeting of the Central Veterinary Society. The animal had picked up a

nail and was slaughtered nine days later. The nail went through the frog, tendon, and navicular bursa, and actually punctured the navicular bone. He did not think it any use attempting to treat the case.

Since then he had come across a case in which he was asked to act as referee for an insurance company. This horse picked up a nail last October, and was only killed a week or ten days ago, and from the foot he took the second navicular bone shown. The horse was acutely lame, but there had been some little discharge from the heel above the coronet, which would close, and there would not be much discharge, but in a fortnight or three weeks the horse would get more acutely lame, another slight abscess form and burst. That had gone on all this time. The owners wanted to have the horse slaughtered, but the insurance company would not give permission. He gave it as his opinion that the case was not worth treatment, and it was destroyed. The foot was sent him and on dissecting it he found the extensor pedis in exactly the condition he had described at the Central as likely to occur in long-standing cases of this nature. At the back of the navicular bone the tendon was adherent, and there was exostosis all round the rim of it, but the joints were not implicated. The horse would walk moderately, but if he touched his toe he hopped with it in the air. There was some acute inflammatory phenomena in the space above the navicular bone, and immediately behind the coronet bone. It was from there that the discharge found its way out at the back of the heel.

Mr. WALLIS said he had one case, and the horse was shot next day. The bone was broken in two. This horse had picked up one of those square French nails—an abominable thing.

Mr. McTURK exhibited a specimen of double intussusception in the dog, obtained on post-mortem from a greyhound three or four months old, which was thought to have worms, but he found only one worm in the bowel. This pup had been ailing for about a fortnight, and was found dead one morning. It had probably been dosed for worms, and he did not know whether invagination of the bowel was subsequent to it, or whether that might account for no worms being discovered in the intestines.

The PRESIDENT proposed a vote of thanks to the gentlemen who had brought the specimens which, he said, added greatly to the interest of the meeting. He was glad that on this occasion they had more specimens than usual.

Mr. SMITH, SEN., seconded the vote of thanks, and it was carried.

PURPURA HÆMORRHAGICA.

By Prof. WOOLDRIDGE, R.V. Coll: London.

It is very difficult to say what is really the best name for this affection since the precise etiology is unknown. Under these circumstances it is probably best to call it by one or other of the most pronounced symptoms, and if so then either Petechial fever or Anasarcous fever should commend themselves as being about the most appropriate. Some English writers (Williams and Robertson) in former times have described the condition as "Scarlatina," but as there is not any resemblance to or association with that disease in the human subject, nor is it transmissible to man, the name is open to very great objection.

Etiology. As I have just anticipated, the true exciting cause of this affection of the horse is unknown. It is often said to be a microbic affection, and an infective disease; by some it is said to be a septicæmia due either to an ultra-visible virus, or to a streptococcus; or a staphylococcus; by others it is said to be due to a bacillus or to a pasteurella. It may be that the local

lesions are caused by a plugging of some of the capillaries with organisms.

When one gets so many of these theories suggested and with comparatively little experimental evidence to support any of them, one is usually safe to conclude that although there may be plenty of conjecture on the subject, there is really little or no exact knowledge. Against the theory of specific microbic origin is the fact that no definite micro-organism has yet been isolated capable of producing the affection, and moreover transfusions of blood from affected to healthy horses and inoculations of discharges from affected animals have all been uniformly negative. But although the exciting causes of petechial fever are obscure, there are certain predisposing causes which are frequently in operation and with which we are all quite familiar. Although purpura is said to occur occasionally as a primary affection, it is far more frequently a sequel to or a complication of some well marked debilitating disease, such as strangles and influenza, while cases are recorded following various infected wounds, chronic abscesses and suppurating lymphatic glands. Dieckerhoff, whose views on purpura are always worthy of consideration, regards the disease as an auto-intoxication arising from various primary foci, such as suppurative catarrh, suppurating lymphatic glands, etc., due to micrococci, and causing irritation or other injury to the vessel walls, so as to lead to hæmorrhage. Cadeac considers it to be due to the absorption of any bacterial toxin having a vaso-dilatory action.

I am inclined to the belief that the reported primary cases of purpura are really secondary, but that the primary condition may have escaped observation, for the mildness or severity of the primary affection even when observed, appears to bear no indication of the probability or otherwise of an attack of purpura. An animal may have a comparatively mild attack of strangles or influenza, and appear to be doing quite well, and suddenly develop purpura hæmorrhagica; while other horses in the same stables may have a very severe attack of the primary affection and yet make an uneventful and uncomplicated recovery. In such stables there may be a single case of petechial fever, or there may be several, but one is quite unable to find any causes operating in the affected that are not also present in those that escape the unfortunate sequel.

Clinically, the disease is often associated with bad hygienic conditions such as dirty stables, badly ventilated and badly drained, and with bad flooring, and sewage contaminated water. By many it is thought to be directly attributable to such conditions. But purpura hæmorrhagica may occur in ideal stables where none of these bad conditions obtain, and again debilitating diseases as strangles and influenza are quite common in the worst stables without purpura occurring as a sequel. Such conditions then can only be regarded as contributory inasmuch as they tend to reduce the vitality of an animal and mitigate against his making a good and complete recovery from his primary complaint.

The condition, then, would appear to be due to an exhausted state of the animal's vitality through previous disease, producing alterations in the constitution of the blood, such as a reduction of the fibrin-forming elements, and this together with great loss of tone of the heart and the capillaries favours hæmorrhages and transfusions.

Animals affected. On this point I should particularly like the experience of the members of the Society. I have not seen the condition in any other animal than the horse, and though the donkey and mule are susceptible to most equine affections, I have not met with it in either case. Nor have I seen it in cattle, though it is stated to occur by various Continental authorities. In cattle I have seen cases of anasarca of the limbs, and

under the sternum and abdomen, which might possibly have some resemblance to the equine affection, but I have usually regarded them as due to local causes and much more amenable to treatment; and moreover they have not been accompanied by the petechial markings on the visible mucous membranes so typical of the condition in the horse.

Symptoms. Apart from the common history of previous disease from which the patient may appear to be making a good recovery, the special symptoms of purpura hæmorrhagica are usually developed rather suddenly, and may be well marked when first observed, sometimes they appear gradually and in succession. The most characteristic features consist of petechial markings on the visible mucous membranes, and cedematous swellings of dependent parts. The petechiae may be seen best on the nasal mucous membranes, the conjunctiva over the membrana nictitans, and inside the lips. If the latter are completely everted the ecchymoses are generally very obvious. In the mare they may also be seen on the mucous membrane of the vulva. They consist of blood spots varying in size from that of a split pea to the size of half-a-crown, or larger where several have coalesced. A nasal discharge may accompany them and may be slightly blood tinged. They occur suddenly and may disappear as suddenly, sometimes reappearing.

The swellings are more or less characteristic and, as already stated, they affect principally the dependent parts; the muzzle is usually one of the first seats, then one or more limbs, the eyelids, and under the breast and abdomen. They are cold and painless, and easily pit on digital pressure. The upper margin on the limbs usually has a sharp line of demarcation suggestive of the effect that would be produced by tying a cord round the upper part of the limb. A similar sharp demarcation is present at the anterior margin of abdominal swellings. At the muzzle the swellings, beginning at the nostrils and lips, extend upwards and then usually end abruptly, and if a headstall is on, its weight, even if loosely fitting, may produce a groove in the swelling. A curious feature in some cases is the sudden disappearance of a swelling in one region, and at the same time the appearance of one in another place. In many cases there exudes into the surface of the skin droplets of a sero-sanguineous fluid with no tendency to coagulate, and in horses with a light skin, as greys or creams, petechial markings may be seen.

There is usually considerable depression, the head hangs down and increases the cedema; the pulse is frequent, soft, feeble, and sometimes irregular. The internal temperature is rarely very high, it usually oscillates between 102 and 104° F. The appetite, which was probably improving on his apparent recovery from his primary affection, again fails, and this may be further intensified by the swollen lips interfering with prehension. The swelling of the nostrils may cause marked dyspnoea, and even asphyxia in exaggerated cases if tracheotomy is not performed. The swelling of the limbs interferes with flexion of the joints, causing difficulty in moving about, sometimes giving rise to fissures about the knees, hocks, and pasterns. The cedema under the body and elsewhere may so interfere with the local cutaneous circulation as to cause large sloughs of the skin and the development of large open wounds, which may become infected and lead to serious complications. Other systematic symptoms depend on what internal organs are implicated. One of the worst complications is a suddenly occurring cedema of the lungs, which will probably kill from asphyxia. Also pneumonia may occur as the result of saliva, food, or even drenches passing down the trachea. Such cases are usually septic and fatal. The alimentary tract may also be involved and enteritis produced, with diarrhoea and colicky pains. Such cases are also very unfavoura-

ble and usually terminate fatally. The urine is often rather scanty and albuminous, and in the male micturition may be difficult from a swollen sheath or pendulous penis. Nervous symptoms are also recorded, and vary from paraplegia when the spinal cord is affected, to fits and convulsions or coma when the meninges and brain are involved. Such cases are always fatal.

Diagnosis is very difficult, and should be guarded. The affection is fatal in about 50 per cent. of cases. Sometimes all the characteristic symptoms will disappear in 24 hours and the horse make a complete recovery. In other cases, when all appears to be going well the patient suddenly becomes worse and dies. The best indications are the gradual improvement in heart and general circulation, the gradual return of the appetite and reduction of the swellings, the absence of marked dyspnoea and of the colicky pains. In the more favourable cases a long period of convalescence—a month or six weeks is absolutely essential to a good recovery, and it is here that one is frequently handicapped by the owner, who thinks that a horse that has returned to his appetite a few days or a week is necessarily quite fit to go back to work. If a horse is sent to work too soon he is very likely to get a relapse of some kind, either pulmonary or intestinal, and will probably die.

In fatal cases death may be due to a variety of causes, viz.:—cedema of the brain, asphyxia from cedema of the lungs or from the swollen nose, pneumonia, enteritis, exhaustion, or from septic infection of sloughs of the skin.

Treatment. In the first place provide the best possible hygienic conditions, a nice warm loose box with plenty of fresh air, and well drained.

Careful nursing and judicious feeding are of the highest importance. Foods should be easily digestible and of a laxative or demulcent nature. They should be offered in small quantities, and frequently changed. Amongst the best are linseed mashes well boiled, oatmeal gruel, eggs and milk, hay-tea and barley water. A little green meat if available, and a little steamed meadow hay with a good aroma. To all or any of these may be added a little extract of malt. Of medicinal agents, stimulants may be useful, such as brandy, ether or port wine, but the chief objection to them is that they will have to be given as a drench, and I do not approve of drenching at all if it can possibly be avoided. The same applies to the old fashioned and well spoken of remedy *Ol. tereb. ʒii* in a pint of milk given twice daily. Potassium chlorate is another of the old remedies and it can be given in the drinking water (too depressant; may cause hæmolysis).

Each of these agents is highly spoken of by some practitioners and just as highly condemned by others. For my own part I care for neither; *Liq. ferri perchlor.* in doses of ʒss. or ʒi. b.i.d. is often recommended, and is useful. Adrenalin is given sometimes in doses of ʒi. of the 1-1000 sol. hypodermically, but where there is already a danger of sloughing of the skin I regard hypodermic injections of any kind as too risky. The medicinal treatment I prefer consists in the intra-tracheal injection of Lugol's solution of Iodine as recommended by Dieckerhoff. The solution consists of *I1*, *K1* 5, *H2O* 100, and the dose is from ʒss. to ʒii. twice daily for the first two or three days, and once daily for several days afterwards. The head must be raised and the strong sterile needle inserted between the rings of the trachea. The fluid must be injected very slowly indeed, and then should not cause a fit of coughing. Combined with this, if it is possible to ball the horse and he can swallow fairly easily, I recommend *Potass. iodid. ʒii.*, and *Acid aceto-salicyl.* and *Pulv. nucis vom.* aa ʒi. in bolus twice daily, or as an alternative in electuary. If that is not practicable omit *Pulv. nucis vom.* and give the other in the drinking water or other foods. Fresh nuclein in ʒss. doses daily hypodermically is very

good. It appears to increase leucocytes in number and vigour.

Collargol has been recommended very strongly, but it does not appear to have answered as well as anticipated. It is given intravenously at the jugular—doses of gr. vi.-xii. in 1% solution in sterile water.

Various vaccines and sera have been used, but I doubt if they are any good, as the specific organism—if there is one—has not yet been isolated. Polyvalent, anti-streptococcus, and antistaphylococcus vaccines and sera are the kind used. (Jensen's polyvalent serum, *Veterinary Record*, 21/2/14.)

Local treatment may be required, but the swellings must not be scarified to relieve the oedema, as that only increases the probability of sloughs. If sloughs have occurred then treat them with ordinary antiseptic emollient and protective dressings. Moreover, do not attempt to reduce the swellings with pressure bandages. Use bandages for warmth if necessary, but let them be quite loosely applied. They are better not used at all. Your client may want some local application. If so give him a mild, harmless one, as a lead lotion.

One more point, and that is that if the nasal swellings threaten to asphyxiate then tracheotomy may be performed, but do not be in too big a hurry owing to the great dangers from infection in this condition. Yet do not hesitate if it is really needed: use discretion.

When you have done your best you must consider yourself and your client fortunate if you save more than the half of your cases.

DISCUSSION.

The PRESIDENT said they were under a debt of gratitude to Prof. Wooldridge for coming so far to give them such an interesting paper. If not one of the most fatal diseases they had to deal with, it certainly was one of the most troublesome. He had hoped the Professor would have something satisfactory to tell them as to the etiology of the disease. It was very necessary to ascertain the cause, but at present even the nature of it was hardly known. It seemed to him to be an affection of the blood capillaries rather than of the blood itself, and brought on by some debilitating disease. They did not get purpura unless an animal had already been debilitated, generally by some suppurative disease. Prof. Wooldridge estimated 50 per cent. of deaths, but this seemed rather high. He might have been rather fortunate, though he had kept no strict record. In *The Record* a writer spoke of a mortality of 40 per cent. which he also considered a little high, because mild cases of purpura occurred with a few petechiae in the nostrils, and a few swellings about the nostrils and legs; these would get well. If they restricted themselves to bad cases, with huge swellings on the head or limbs, then 50 per cent. was rather low. He thought they got more mild cases than bad ones. In the old days, before stables were kept in the hygienic state they are now, the cases were treated by half-suffocating the patients, and they nearly all died—which was not to be wondered at. Prof. Wooldridge attributed death to asphyxia, but in his opinion this was not the case. Suffocation did not often happen now because they adopted tracheotomy. When the lungs were affected it might be what one would call pneumonia. He was glad to hear the Professor say he did not believe in scarifying the swellings. Some people considered scarification necessary, but he did not remember a case in which it was necessary and had never seen it done.

Mr. WALLIS said he was able to pat himself on the back after what the Professor had said, because it agreed with his practice. He thoroughly agreed with what was said about hypodermic injections, for these invariably meant a large swelling which gave a good deal of trouble, and probably sloughing, whatever

measures they took to make the wound thoroughly aseptic. He believed in Nuclein, and in preference to giving it hypodermically had given it in milk. In the last case he had, finding a mare would drink milk instead of water he gave 5 per cent. Nuclein in milk and she took it nicely. He was obliged to perform tracheotomy as he was living twelve miles off, and he dare not leave the mare the night through, and the farmer was able by means of a very small funnel and six or eight inches of $\frac{1}{4}$ -inch tube to give the solution through it very slowly night and morning, half-an-ounce at a time. This was instead of his having to go over and inject it into the trachea. He had found no trouble in healing, and regarded this as partly due to the constant use of Iodine, and also when the tube was removed being very particular to swab out twice a day with cotton wool, and dress with Tincture of iodine on each side. Desiccated malt extract was a very useful thing, and if dissolved in warm water and put into milk, horses would take it when otherwise they would not touch it. It was a very good digestive and stimulant. In big cart horses he had found great relief from hay bandages, not put on tightly, to keep up the temperature rather than to exercise any pressure. The bandages were put on at least once or twice a day, and he had always found them beneficial. Feeding was a very difficult matter, and they had to exercise their ingenuity to get their patients to take sufficient. He did not believe in drenching if they could get medicine into them in any other way.

Mr. Low said he had a case a fortnight or three weeks ago. The horse was very bad with pneumonia and pleurisy, and on some days got on as well as possible, but there was always some lingering symptom he did not like. He watched very carefully and said the horse might get some other trouble or have a relapse. He got a message to go at once. One of his assistants went and reported that the horse had all four legs swollen up as big as his body with a temperature of 105, and pulse 80. He went next morning and found the horse had the typical symptoms of purpura. He gave Iodine and Iodide of potassium as a draught, continued it for several days, and the horse got better for a week. Then he had a relapse, with pulse up to 100, and seemed like dying, but the treatment was continued, and next day he was very much better. This went on for a week and then the horse got down in his box and could not get up. It was a small box with no roof to pull him up. He turned him round, gave him a push, and eventually he got up, blowing very hard, pulse up tremendously, and all the symptoms as bad as they could be. He continued the treatment, telling the attendant to give the Iodine and Iodide of potassium solution a tablespoonful at a time, and not to hurry if it took him half-an-hour. From that time the horse had improved and made a complete recovery. He had treated several other cases similarly with success.

He had another case in which the horse had tremendously swollen limbs and never moved once in 56 hours. He made a good recovery, and was sold for £50, although the owner had offered to sell it for 30s. when ill.

Mr. BUCKINGHAM asked whether Prof. Wooldridge had observed on post-mortem any lesions on the endocardium or even in the pericardium. Had he any experience of giving a dose of physic in the early stages of purpura?

Mr. SYDNEY SMITH, junr., asked Prof. Wooldridge if exercise was not of value in regulating the swellings. He had found in a few cases he had that a reasonable amount of daily exercise had been of considerable benefit.

Mr. SHIPLEY said there had been an attempt to give this disease five or six names, and the Professor really

styled it a petechial fever. It was most unfortunate that ridiculous names should be given to the different diseases. Was purpura a fever? Was it generally denoted by a temperature? In his experience it was not. It would be much better if they left out fever, as in milk fever and other things, and he thought they should stick to the old title. There was one symptom, or series of symptoms, not mentioned which occurred frequently—the skin lesions. He had seen many cases where the animal appeared to have something like urticaria, elevation of the hair in patches without any huge swellings about limbs or head, but petechial spots in the membranes and other symptoms of purpura. In several cases of recovery hair came off in round patches like ringworm. In one year he had eight or ten similar cases. Last year in Yarmouth there were many cases of purpura, and many died, but they were not of the kind he had just described. The colic and so-called pneumonia he was not quite prepared to accept as pneumonia, and he believed this was borne out by post-mortems. The colicky pains and apparent pneumonia was nothing more than hæmorrhages into the bowels and lungs, and they did not get real pneumonia as the cause of death. He had made post-mortems whenever possible. He did not agree with Prof. Wooldridge at all in regard to feeding. He did not believe soft foods or laxatives were indicated in cases of purpura. It was difficult to know what to give, but his view was that laxatives or anything which put the bowels into an excitable condition tended to hæmorrhage, and should be avoided. A dose of physic he would look upon as deadly poison. He heard prescribed balls of nux vomica and other things, but he wanted to know the object in giving this and potassium iodide. What was the object of giving iodine in any form? He appreciated that iodine was useful, but Prof. Wooldridge should tell them why he prescribed iodine, or why they had used turpentine. Collargol was suggested, and he would like to know what it was and its therapeutic action. They ought to know a little more about the drugs they used, and why they used them. As to tracheotomy, if there was any suggestion of huge swellings about the head or nostrils, and any interference with respiration, the sooner they used a tracheotomy tube the better, because this put the parts affected at rest and gave a better chance of recovery. His experience had not been that it was difficult to get healing. Prof. Wooldridge, practising in a big city, had very difficult conditions. In a country town they had a much better chance of dealing with their animals—in better air, with better stable room, and not so much danger of infection from septic matter as in big cities. If there was any doubt in swelling of the head in purpura they should insert a tracheotomy tube, which made the administration of Lugol's solution easier, and saved the trouble and danger of frequent subcutaneous injections.

Mr. ROBERTSON thought it would be very bad practice to push in hypodermic injections night and morning; tracheotomy was much better. He wondered how it would be to leave in a big tube as they did for husk in calves, for two or three days.

Prof. WOOLDRIDGE, in reply, thanked the members for the reception given to his paper. Nobody apparently had referred to the occurrence of purpura in the ox, ass or mule, and he took it nobody had had experience of it in these animals—(Several members: That is so)—but on the Continent it was said to occur not infrequently in cattle. He had seen cases of swollen extremities in cattle that might be confused with it, but had never seen purpura hæmorrhagica in the ox. Mr. Little thought most deaths occurred through pneumonia, not from suffocation; and Mr. Shipley did not think death arose from pneumonia. There they had two different views. In his own opinion death occurred from either, but under different conditions. In the majority of

cases death was not the result of pneumonia, and he did not wish to convey that. In the vast majority of cases it was due to œdema of the lungs, the same condition attacking the lungs as in the subcutaneous tissues and the mucous membranes. Pneumonia occurred only in those long drawn out cases, not in those that died within a week. In cases where they got œdema of the lungs they also got those small hæmorrhages corresponding with what they saw on the membranes, and sometimes even larger. They got them in the lungs as large as a walnut. Local lesions occurred in the course of this well-marked œdema, and death then resulted from suffocation. Mr. Little thought he meant suffocation from swellings in the nose, but he had not that in mind. Asphyxia was more frequent from œdema of the lungs. He was glad Mr. Wallis agreed with his deprecation of hypodermic injections where they could be avoided. He had been inconsistent, for he recommended it should be avoided, and later on referred to nuclein which might be given hypodermically, but he found one got better results from its use hypodermically than when given in any other way. Mr. Wallis got his case to take it voluntarily, and nearly all their patients would do so. It might be better and safer to follow Mr. Wallis suggestion and let it be given by the mouth, or even per rectum. Given in a little warm normal saline of blood heat it could be absorbed from the rectum just as easily as from the stomach. He was rather interested in Mr. Wallis' use of hay bandages and recommended them very strongly in swollen legs from lymphangitis, with a certain amount of pressure, but he had not resorted to them in purpura because pressure was contra-indicated. Mr. Low's cases were very interesting, and he was struck with the benefit derived from larger internal doses of iodine, but Mr. Bloye, of Plymouth, said he had no good results from this treatment. That made it difficult for them to choose what was the best method. Mr. Buckingham asked if he had observed lesions of the endocardium, and he regretted that he did not refer in his paper to post-mortem appearances in cases that had died from purpura. These ecchymoses might occur all over the body. They might be found in the peritoneum, the pleura, and the endocardium, also in the muscular tissues, and sometimes in the liver substance and kidneys. When there were any in the kidneys they had albuminuria. The suggestion of a dose of physic struck him in the same way that it did Mr. Shipley, and he would regard it as highly dangerous. He would like to ask Mr. Buckingham if he gave it.

Mr. BUCKINGHAM said it was an idea amongst practitioners in his younger days, twenty or more years ago when he heard it recommended, but he had never seen it carried out. He had not resorted to it himself.

Prof. WOOLDRIDGE said he never regarded a dose of physic as indicated, although there might be a little arrest in the passage of the fæces, but this might be due to the patient having been off his feed from the original infection, and not having much ingesta to pass. Physic was not required, and was very likely to set up superpurgation. He would hesitate very considerably before using it. Mr. Sidney Smith, jun., wanted to know whether exercise was of any advantage. He thought it was not, and that it was contra-indicated. With a horse so debilitated, the more near approach to complete rest that could be given the better. (Edematous legs from lymphangitis, puffy and gummy legs were a different thing. As a horse became convalescent, then a little judicious exercise gradually progressive was indicated, but not until then. He was glad to find Mr. Shipley in such fighting form. He was in excellent trim. He wanted to know if purpura was a fever, and his reply was emphatically, Yes, but not a high fever. The normal temperature was 99 to 101°, anything over that was a febrile temperature. The average range of temperature in purpura is 102 to 104°, sometimes 106°.

Mr. Low quoted 105°. He thought they were justified in regarding it as a fever in the large majority of cases. The main objection to the term purpura, as applied to the horse, was that the same name applied to a disease in the human being with which there was no connection or association. He certainly omitted reference to the symptom of urticaria on the skin, though he had seen it, and should have referred to it. It would occur in most cases if they saw them early. It was often the first stage to the more pronounced swelling of the skin. In some cases the more pronounced swelling did not occur, and the local lesions were quite small and limited and suggested urticaria, rather like circular weals of hair sticking up. He had not seen the hair coming off in patches like ringworm. It was interesting, and he would look out for it in future. If he had had his attention drawn to it he would probably have thought it was a case complicated with ringworm. The objection Mr. Shipley pointed out with regard to pneumonia causing death he had already referred to. He agreed with him absolutely. The condition Mr. Shipley referred to was œdema of the lungs. Mr. Shipley did not care for soft foods, and thought they were not indicated because they tended to produce hæmorrhages, but the Professor said he could not see how a bland, non-irritant demulcent passing through the intestines could produce hæmorrhages. On this point he was afraid he and Mr. Shipley would continue to hold divergent views. When it came to feeding a horse with purpura on hard dry foods he would often refuse to touch them. He could not manipulate them with his lips, prehension was interfered with, and they had to resort to something he could partly suck and slop up. He would take all risk of producing possible hæmorrhages into intestines by a demulcent. The question as to the action of drugs employed was most pertinent. He refused to use any drug unless he could see a probability of some good arising therapeutically. He did not believe in the indiscriminate use of any drug because it had been said to do some good. Those were the reasons why he should object to turpentine which was thought to screw up the capillaries and stop hæmorrhages. He could not see how any advantage could arise from Potassium chlorate or from Liq. ferri perchlor. Potass. chlor. was recommended because it was thought that purpura had something to do with the lack of oxygen, and because Potass. chlor. when heated in a test tube yielded oxygen. So it was thought it would yield something similar in the blood when administered. If the blood required oxygen it would get it from the air inspired. Then there was the danger of producing hæmolysis and a depressant action in an already depressed animal. As to Pot. iod., Aceto-salicylic acid, and Nux vomica, he did not know any drugs which reduced œdema so well. Aceto-salicylic acid had come forward as one of the best febrifuges they possessed; and it diminished the chance of a suddenly rising high temperature and acted as a general internal antiseptic to diminish or overcome the ill-effects of possible secondary infection. They all knew the effect of nux vomica as an excellent tonic, and it was for its tonic effect that he used it. Mr. Shipley asked what Collargol was. It was a colloidal preparation of silver, non-irritant and antiseptic, and for that reason it was injected intravenously. Reports seemed to say it had come up to expectations.

Mr. Shipley joined issue with him on the question of tracheotomy. He still thought it unwise to perform tracheotomy when there was some slight swelling of the face and nose. If, however, there was real necessity through the respiration being affected, then tracheotomy should be performed. He could see it was easy to use Luzol's solution through the tracheal wound, but the effects of a minute puncture were very much less than the large wound necessary for tracheotomy. There was a greater danger in the towns with regard to some of

these wounds than there was in the country and the stables were not so well looked after. In the towns they were more in the hands of the stablemen whose ideas of cleanliness were far removed from one's own. The danger from the tracheotomy wound was far and away greater than from intra-tracheal needle punctures, and that was just the difference between the two methods.

A vote of thanks was unanimously passed to Prof. Wooldridge.

On the motion of Mr. W. Waters, the retiring Hon. Sec. and Treas. (Mr. Sidney Smith, jun.) was thanked for his services during the past year.

ELECTRICITY FOR PATIENTS.

The PRESIDENT handed round for examination a new appliance termed an electro-neurotome for the purpose of administering a mild current of electricity in cases of rheumatism. A dry battery is carried with the appliance which can be very easily used for a period up to fifteen minutes daily. Thus far it had been found that the cases on which it was used had all improved. Only a weak current was advisable and horses did not object to it so much as might have been imagined.

The meeting ended with a vote of thanks to the President.

A. C. HOLL, M.R.C.V.S., Hon. Sec.

LANCASHIRE VETERINARY MEDICAL ASSOCIATION.

(NATIONAL V.M.A.—NORTHERN BRANCH.)

The fifty-second annual meeting was held at the Grand Hotel, Manchester, on Friday, February 20th. The President, G. H. Locke, Esq., in the chair.

Minutes. On the proposal of Mr. Pillers, seconded by Mr. Packman, the minutes of the last annual meeting were taken as read.

Nominations: Elections. Mr. ROBERT ISHERWOOD, Warrington, and Mr. CHARLES WENTWORTH ELAM, Liverpool, were nominated for membership by Mr. Pillers.

The following were unanimously elected members: Messrs. E. H. CURBISHLEY, Alderley Edge, and W. P. RUTHVEN, New Mills, were proposed by Mr. G. H. Locke, seconded by Mr. Brittlebank.

Mr. C. BLACKHURST, Broughton, Preston, proposed by Mr. Packman, seconded by Mr. Brittlebank.

Balance Sheet. Mr. STENT, in presenting the balance sheet, assumed that every member had received a copy. The cash in the bank at the commencement of the year £28 15s. 7d. The year had been rather more expensive than usual inasmuch as five meetings had been held, including a special one, and the affiliation fee to the National V.M.A. was an additional item. There was £17 10s. 9d. outstanding for arrears of subscriptions. The year closed with a deficit of £1 18s. 2d. The number of members showed a slight increase, the number being 94, and he hoped they would soon make this into one hundred.

Mr. TAYLOR, as one of the auditors, moved that the balance sheet, as presented, be adopted. Mr. Packman seconded, and it was carried.

Mr. BRITTLEBANK, in discussing the balance sheet, said the Council felt they would have to consider the financial position of the Association with a view to cutting down expenses. The question of arrears of subscriptions should not occur to the extent it does.

After some discussion as to economising on the item of dinners provided at each meeting, Mr. Brittlebank gave notice of motion of alteration of the rules at the

next meeting. The alterations would be considered by the Council.

WILLIAM HUNTING MEMORIAL FUND.

Mr. TAYLOR whilst feeling somewhat diffident owing to the financial position of the Association, gave notice that he intends to move that a donation be made to the William Hunting Memorial Fund. He regretted to see that so few men in the North had subscribed individually. Mr. Hunting was a bulwark in the profession. There had been no public recognition of his eminent services in veterinary and sanitary science and in public health hygiene during his life, and the least they could do was to perpetuate his memory in some tangible form. Parliament had failed to take cognisance of his abilities and efforts. The veterinary profession held Mr. Hunting in high esteem, and they should see to it that their subscriptions were considerably increased before the fund closed.

PRESIDENTIAL ADDRESS.

Mr. G. H. LOCKE, M.R.C.V.S., Manchester.

Gentlemen,—My first duty on taking the chair is to thank you most sincerely for the honour you have conferred on me by re-electing me your President for the ensuing year. Knowing full well that I follow men of far greater attainments, I feel very diffident, more especially as it is the International year; still, it will always be my earnest desire to further the interests of the Lancashire Association, and so keep up to the high position it holds in the veterinary world.

I rely upon the officers and members for their indulgence and support during my year of office, and wish to place on record my high appreciation of the services rendered by our officers during the past year.

As I have already mentioned we are to be favoured with the International Veterinary Congress being held within our shores this year; the programme has already been published. It is not my purpose to criticise the list of papers, as one must recognise the difficulty in arranging for a conference of such magnitude, but it seems a matter of regret that the ordinary practitioner of this country should be so scantily represented. Surely at a time such as this when our bovine population is becoming increasingly valuable, a section might have been devoted to the consideration of some of those presumably non-specific diseases so commonly met with in every-day practice, and about which much more information is desirable. In passing I should like to mention how pleased the Association is that our worthy Hon. Sec. (Mr. J. W. Brittlebank) has been honoured by an invitation to read a paper on the Public Health question, and, on your behalf, I tender him our heartiest congratulations. I am glad that the response to the appeal for funds has been so far satisfactory, but I understand that the amount required is not yet complete, and I hope that it will not be long before the omission to subscribe, on the part of some of our members, is rectified. It is only reasonable that all ought to take a share, however small, when the honour of their profession is at stake.

Unfortunately we are not supported by our Government as is the case in many other countries, and we ought to feel very proud of the position we hold as a profession, considering we have had no financial assistance. It was very gratifying to read in the recent speech at Crewe by Mr. Runciman, his promise of a scheme whereby financial assistance may be forthcoming for the education of the Veterinary student. He also congratulated the country on its freedom from serious outbreaks of contagious disease, but little credit is given our profession for the part it takes, and has taken, in the control and stamping out of those diseases.

One cannot but view with concern the state of the finances of the R.C.V.S., and hope that every member of the profession will leave no stone unturned to get the Bill now before Parliament, placed on the Statute Book. The future of our profession is so deeply involved in the passing of this measure.

It is pleasing to note the excellent work which is being done at home and abroad by the members of the Army Veterinary Corps, and if only the people responsible would place the question of the supply of remounts under the absolute control of the A.V.C. some proposal of national benefit might accrue.

It was very gratifying to note that two veterinarians were included in the New Year's honours list.

As you are all aware, the newly constituted National Veterinary Association is now an accomplished fact, and has already given evidence of its power to serve the interests of the profession.

There can be no doubt that the profession is undergoing great changes, and, in many ways in the direction of progress, but if we are to obtain the full measure of our deserts our professional motto must be made a real and not a fictitious one. To secure real unity I consider it the duty of every veterinary surgeon, old and young, to join some association such as ours, all of which are now welded under one great central body. One does not know whether to be too pessimistic about the future, for as surely as one field of activity ceases to be lucrative, then another will open, if we are alive to our opportunities.

May I be pardoned in closing in once more reminding those who are not already members of the National Benevolent and Defence Society the advisability of joining as soon as possible; one never knows when its services may be required in either department, and if we are fortunate to never need assistance in any form, it is some consolation to know that we are assisting and doing a little to help our less fortunate brother.

I thank you, gentlemen, for your kind attention, and in conclusion express the hope that you will, by your attendance and support at the meetings, help to make the ensuing year as successful as any previous one.

Mr. McKINNA heartily proposed that the best thanks of the Society be given to the President for his address. Mr. Carter expressed pleasure in seconding, and it was carried with applause.

THE DINNER.

For the second year in succession ladies were invited and were well represented. The attendance of members included the President, Messrs. Carter, McKinna, Taylor, Noël Pillers, Spruell, Packman, Heyes, Noar, Stent, Woods, Wolstenholme, Brittlebank, Clarkson, Garnett.

The visitors included Prof. Bradley, Prof. Delépine, Dr. Niven, the following members of the Manchester City Council: Alderman Jones, Alderman Turnbull, Councillors Kay, Chantler, and Bowie, also S. H. Renshaw, J.P., J. H. Stennett, J. Rowland Albinson, W. Vernon; Messrs. G. W. Carter, F. P. Carter, Taylor, jun., R. Rogers.

Apologies for absence were received from Messrs. Mattinson, Abson, Lawson, Hughes and Sumner.

The PRESIDENT gave the toast "The King," accompanied with musical honours, Madame Conway admirably taking the solo.

The PRESIDENT also gave "The Queen, Queen Alexandra, the Prince of Wales, and other Members of the Royal Family." This toast was loyally responded to.

The next item was a duet "Watchman, what of the night?" which was well rendered by Madame Conway and Mr. Hudson.

Mr. PACKMAN, in giving the toast of "The Imperial Forces," said he understood it to embrace three branches of the Service, namely, the Navy, the Army, and the

Voluntary Forces. The Navy has undoubtedly an untarnished record, and he felt sure he was voicing the earnest desire of everyone present in hoping that nothing would happen in the future to weaken or destroy its glorious history of which every Englishman was justly proud. The second line of defence—the Army—whilst not numerically strong, compared with our continental rivals, they had in the past held their own, and to use a sporting phrase, the light weight has usually come out on top. The science of warfare has made great progress, and in future the enemy would have to be met not only on land and water, but also under water and in the air.

To the third line of defence—our voluntary forces—he thought a deep debt of gratitude was owing. The men gave up their time and leisure for the good of their country. Much was being done to make this branch popular, and he hoped the efforts would be crowned with success. He coupled with the toast the name of Lieut. Heyes.

Mr. Vernon then sang "Songs and Operas in Rag-time."

Mr. HEYES felt some embarrassment in responding on behalf of the Imperial Forces. However, the toast had been proposed in such kindly terms and responded to so generously that he felt it incumbent upon him to thank them on behalf of the Forces, of which he was a humble member. Being a member of the Territorial Force he was, as it were, only a distant relative of the Army and Navy, but he believed the praise bestowed on these two branches was justified.

It is, he said, the ambition of the Territorial Force to come up to the standard of excellence possessed by the Regular Forces. Whilst there were difficulties in the way, they had the right spirit permeating the men, and it was their desire by training to show the young men of to-day how to be of service to the country, and also to better themselves in every way. The veterinary section of the Territorial Force is not very strong, but is improving, and he hoped to see the day when it will compare favourably with the R.A.V.C.

Mr. McKINNA, in the absence of Mr. Sumner, proposed the toast of "The Medical Profession." In doing so he said it was a great honour to propose a toast to a profession to which they owed so much. In the tottering days of the veterinary profession—in its early history, the medical profession came to their aid, both as teachers and examiners. Up to the present the relationship had been most harmonious, and he congratulated Manchester in particular on the goodwill which existed in the city between the two professions.

The medical profession had passed through stirring times during the past year, but they still seemed happy, and he hoped they would become happier in the future. It was gratifying to him to hear his own profession referred to as the sister profession, because each had its own work to do, and there need be no jealousy between them. He coupled with the toast the name of Prof. Delépine.

The song "Glorious Devon" was rendered by Mr. Taylor, jun.

Prof. DELEPINE said it was not always the case that the younger sister was ready to recognise the merits of the elder sister; there is usually a tinge of jealousy, but when the friendship which should exist between sisters is able to overcome that feeling, then the friendship is true. It is well recognised by both professions that it is better to fight together, shoulder to shoulder, than to be standing alone, each wanting to possess more than the other. He would remind them of the way in which some of the distinguished members of the veterinary profession are recognised almost as members of his own profession. To mention only a few such as Chauveau, Nocard, Ostertag, Bang, and M'Fadyean. The way in which these names are used constantly by

the medical profession was sufficient indication of the regard in which they were held. What had been said by Mr. McKinna might be reciprocated. It is true the medical profession had the advantage of age, and also true that they had done their best to help when opportunity arose, sometimes in a selfish way, but, he thought, more often unselfishly.

There are changes taking place in the minds of people in this country; not more than ten or twelve years ago there was a time when a man had passed through the medical curriculum giving him entry into the medical profession, everything had been done both for ordinary practice and other services. At the present time there is an application for an additional Charter in which the Royal College of Veterinary Surgeons applies for powers for post-graduate courses and post-graduate diploma in Veterinary State Medicine. This is an instance where the medical profession has shown its insight into the wants of the veterinary profession, and it is in this part of the kingdom that members of the medical profession have appreciated the need of that special training. It was about ten years ago that a movement was started at the Victoria University, at the instigation of members of the veterinary profession, to provide means of obtaining post-graduate training, and they went further and arranged a course in Veterinary State Medicine with a suitable diploma. This was only one instance which passed through his mind, but was a good example of the way in which the medical profession had closely followed the work in which the veterinary profession was closely interested. They were extremely grateful for the kind way in which their efforts had been interpreted. There is work for each to do, work which could not be done by both.

He thanked them for the handsome way in which the toast had been responded to, and begged to assure them that the medical profession will continue to do its best in foul weather as well as in fine.

A character sketch was next given by Mr. Vernon "Jewish Impersonations."

Mr. PILLERS rose with the greatest pleasure to propose the important toast of "The City of Manchester," but at the same time confessed his inability to properly express his opinion of the high place which the city occupies in commerce, politics and science. As Britishers they could not help but realise the importance of Manchester goods throughout the entire world, and it would be a sorry day for the world at large if an earthquake were to engulf Manchester. As Englishmen they looked upon Manchester as one of the foremost cities of the land, and associated with it men of greatness in all spheres of commercial, scientific, and social life. One need only recall the names of Dalton, Owen, Bright, and Cobden. As Lancashire men we talk of the "Liverpool gentleman" and the "Manchester man," but after all he did not think there could be a ny greater honour than to be called a "man." Our Scotch friends who have come here, never to return, would bear him out when he said "A man's a man for a'that." On his way to that function he saw several times the posters "Manchester goods for Manchester docks." He feared, however, the Scotsman had infringed on that patent, and made it read "Scotsmen for all docks."

As sanitarians, and the veterinary profession claimed to be this, they looked upon Manchester in the most favourable light. Great difficulties have to be overcome in sanitation and in progress, and no town has succeeded in doing this better than Manchester. He would mention her great sewage scheme and the way insanitary areas were dealt with. More particularly was Manchester to be praised for her school for training veterinarians in public health work. Her system of meat inspection is what the veterinarian has always been aiming at, and in the attempt to obtain a pure milk supply she is the pioneer. They sincerely hoped that

when other towns sought advice in these matters, and this must often happen, Manchester will say the best method is to employ properly trained public health veterinary surgeons.

There are a few little things that do not please the veterinary profession, but they would be ungrateful to mention horses and the association of slaughter-houses and meat markets with premises where refuse destruction is carried out.

He had pleasure in associating with the toast the names of Alderman Turnbull (member of the Sanitary Committee), and Councillor Chantler (Deputy Chairman of the Markets Committee).

Mr. Kershaw then sang "The Trumpeter," and for a well deserved encore "I hear you calling me."

Mr. Alderman TURNBULL expressed very special pleasure on his own behalf, and also for his *confrères* on the City Council in being present that night. The proposer of the toast had mentioned a few of Manchester's illustrious men, but there were other illustrious men and women living to-day who have done, and are doing a very great deal towards the prosperity and progress of the city. Amongst others, he would mention Dr. Niven, the esteemed medical officer of health, than whom no man had done more for the improvement of Manchester. Also he would mention Mr. Brittlebank, whose work in connection with a pure milk supply was so very valuable. Prof. Delépine had also, as much as anyone, greatly assisted the city to attain its splendid position in regard to public health matters. Coupled with these gentlemen he would like to mention the veterinary surgeons employed by the Markets Committee in looking after the welfare of the food supply of the citizens. They had need to be proud of Manchester, and, personally, he was proud to state that he had been identified with it for over 60 years.

Manchester has a population of about 800,000, and the turnover in connection with its finances was something like 15½ million pounds. Banking returns showed that Manchester stands ahead of every other great city in the United Kingdom except London, and is quite equal to Liverpool, Leeds, Bradford, and Sheffield put together. This success was, he thought, largely attributable to the Ship Canal.

He thought also that the city tramway system was the finest in the kingdom, and mentioned that last year one hundred thousand pounds was contributed from the profits to the relief of the rates. The Gas Committee, with a progressive and energetic Chairman in Councillor Kay, handed over last year £60,000 in relief of the rates. The Electricity Committee also showed a profit and gave over £24,000, so that taking these facts into consideration they had cause to be proud of their representatives, and of their public men. There were something like 21,000 officials employed, being equal to the population of many a good-sized town; this would give some idea of the enormous amount of work to be done. He thanked them heartily for their reception.

Councillor CHANTLER also responded to the toast. In so doing he regretted the absence of the Lord Mayor, for he was sure they would have had an entertaining speech from him, and as Chairman of the Markets Committee the Lord Mayor would, no doubt have had something to say of the work of that Committee. The Corporation of Manchester fulfilled not only a useful but an indispensable service, and a review of its history would show a record of steady advancement and progress all along the line. Time was when gentlemen of high position in the city occupied seats in the Council, but whilst they could not claim this at present it is nevertheless true that those who are now occupying positions of Aldermen and Councillors are doing their duty manfully, and with a disinterestedness worthy of the highest praise.

The work of the Sanitary Committee and other committees had been referred to, but he wished to speak about the Markets Committee, for it was in connection with this Committee that the veterinary surgeons were most closely identified. He was quite sure that what he was about to say would be acquiesced in so far as Dr. Niven was concerned because he is a professional man, but he (Mr. Chantler) had always thought that the veterinary profession was far too modest a body and did not think enough of itself. Time was when the medical profession as well as the veterinary profession, in days long gone by, were not looked upon with the same favour and not regarded as the absolute necessity they are to-day. The veterinary profession now holds a position second in importance to no other profession in the whole world.

Remembering the Acts of Parliaments which have been passed and which had to be administered by the veterinary profession, he thought he was justified in repeating that the profession was too modest. It would not be a bad thing, he said, if there was to be another kind of Health Insurance Act brought into being. The last Act had stirred up the medical profession to a remarkable extent, and if the veterinary profession had to come up against a similar experience it would awaken them to a sense of their responsibilities.

The Markets Committee of the Manchester Corporation is responsible for the administration of the Diseases of Animals Acts and the Orders of the Board of Agriculture and Fisheries thereunder, and is responsible regarding the sale and exposure for sale of unwholesome meat. For many years past the Committee have acted on the policy of employing veterinary surgeons for the inspection of slaughter-houses, that being consistent with the practice followed by governments or other authorities in the United States, on the Continent, and in our Colonies. In connection with his position on the Markets Committee he had had occasion to go on the Continent and could not help being struck with the large part that the veterinary profession, in one way or another, played in the work of the authorities of the great towns there. His Committee believed that the veterinary surgeon is the man best fitted for this class of work by reason of his training, and following out this policy they are employing five veterinary surgeons, in addition to other inspectors. During recent years the duties have been greatly extended in Manchester, and if time permitted he could give statistics showing the enormous amount of work done by these men.

They recognised the distinction between the veterinary surgeon and the medical practitioner and, without disrespect to the latter, see a distinct difference. One looks after the health of human being and is trained for it, the other is trained for looking after the health of animals. There was a time when they had not these Acts of Parliament relating to diseases of animals, etc., but the position is now entirely changed. The duties of the veterinary profession are of sufficient importance to warrant greater recognition from Government departments, and they ought to have a paid veterinary adviser to the Local Government Board. This is becoming recognised in many large cities who employ veterinary surgeons for the inspection of meat and other food. He took it that the objects of their Association were to strengthen their position as a professional body, and he thought they should look to these Government authorities to advance their position.

He went on to refer to the proposed rebuilding of the Manchester abattoirs, and touched briefly on the number of animals slaughtered yearly, and also the volume of trade in chilled and frozen meat.

Dr. NIVEN, in proposing "The Veterinary Profession," said he first of all desired to thank the Association for the honour in asking him to propose this important

toast, and supposed they did so because of the intimate relations which exist between the medical profession and the veterinary profession. It is impossible for a medical officer of health to carry out many important parts of his work unless he has, as a colleague, a veterinary surgeon who can carry out important duties both clinical and pathological. The fact is that the work of the Public Health veterinarian is inextricably bound up with that of the medical officer of health, and it is impossible for the latter to pursue his inquiries into the causes of disease which afflict human beings unless he has all the knowledge which the best veterinary skill can afford him in arriving at the causes which have brought about these diseases in man. Therefore he thought no greater misfortune could occur to any community than to sever those intimate relations which should exist between a Public Health department and the veterinary service. The fact is that any small feeling there is of jealousy exists only in petty and foolish minds. There is no encroachment on the sphere of any veterinary surgeon *by any medical officer who understands his business*. Their spheres of labour lay entirely apart, and there was quite enough for each to do, but it is necessary that the medical officer of health should have sufficient knowledge of the work that the veterinary surgeon is doing to understand the steps which he takes, and to carry out intelligently the administration depending upon his work, but that is all the encroachment which is, or ought to be necessary. Suppose this relationship is severed, see what happens—the veterinary inspector acts independently and the medical officer has no clue as to the manner in which dangerous material is being distributed in the city and bringing about disease with which he has to deal. It is important that the Public Health department should be in the closest relationship with the veterinary service of the city. He wished to make this quite clear before going on to say that although there may have been little jealousies, the medical profession recognises the growth and usefulness of the veterinary profession, and wishes it well in all its works and ambitions. Both are engaged with the same problems and the same difficulties, whether in practice or in scientific pursuits, with the same prospects of new advances and valuable work still to be done.

He would remind them of the history of the Panama Canal. What would have been the use of all the capital and lavish expenditure in the construction of that canal without the intervention of medical skill. It was entirely medical skill which enabled that work to be carried through, and which saved enormous sums of money. The economic value of proper medical work was very great.

There is the same great prospect opening out in Africa for the work of the veterinary service as the result of their research into the diseases of animals.

He had no doubt, whatever, that the prospect of that great ambition now held up would in a few years be fulfilled. He would ask, "What is it makes the wealth of the community?" It is the health of the individuals. It is the training, health, vigour, and intelligence of each unit. That is why the Germans go ahead—because they are splendidly trained, they have made tremendous efforts, they have been favoured in that their cities are new and well constructed. They have trained young people strenuously and well. Every individual scores a little, and these little add up to large amounts in the great competition of nations. That is where these great efforts in hygiene save wealth. It is not entirely so, but to a large extent. It is the same with the work of the veterinary profession, the higher intelligence of the individual, the more care and skill exercised in dealing with individual animals the more rapidly does the country's wealth in that domain increase. So that he held when one of their members—Mr. Holburn—advocated

the more careful training of the practitioner, that was an expression of opinion which many of them would share. He ventured to say that when that effort is put forth that alone will add greatly to the country's welfare. He thought the wealth of the country is largely made by these two professions. He wished to thank Alderman Turnbull for his kind remarks, and in conclusion had great pleasure in proposing the toast coupling with it the name of Mr. Carter, the President of the R.C.V.S.

Mr. CARTER, wearing his chain of office as President of the R.C.V.S., in response, took the opportunity of expressing his grateful thanks to every member of the Lancashire V.M.A. for the loyal support given to him in the election of Council. After being on the Council some 16 or 17 years, and being so near the presidency, it meant a great deal to him to have the support given which had enabled him to be in the position of addressing them as President. He esteemed the honour, which was not only a personal honour, but an honour to his native town. It was also an honour when he remembered that in a big county like Lancashire there were only four practising veterinary surgeons who had occupied the same position; these were John Lawson, Thomas Greaves, Alex. Lawson, and Sam Locke.

The function of the Royal College is the protection of the privileges of the profession, and the protection of the community against fraudulent quackery, which is, unfortunately, prevalent in our towns. It is also a protection against imposters and usurpers.

The profession of medicine, in which he included human and veterinary medicine, was founded on the highest ideals, and the veterinary profession must live up to those ideals. It rests with them to prove their worthiness in discharging them creditably, and to retain unmarred the great possessions handed down by their forefathers. The training that must now necessarily be gone through is comprehensive, and must in itself be one of the best means of exercising the highest intellectual powers. There is no career and no profession in which theory and practice so harmoniously combine as the practise of medicine. Is it not a fact that in our daily life through the act of practice the mind is kept healthy and vigorous. The progress of medicine and knowledge of surgery in recent years has indeed made rapid strides, and in great measure such progress is due to the investigation and manifestation of diseases in the lower animals, for it is upon a knowledge of the lower animal that the two professions are so dependent for their protective skill.

As Dr. Niven had mentioned, he (Mr. Carter) would like to see a still closer alliance of the two professions whereby they could go on hand-in-hand endeavouring to combat disease in the higher and lower animals alike. Pathology had brought into clear relief the intimate relationship between human and veterinary medicine; bacteriology has more particularly contributed to this end by demonstrating hitherto unsuspected channels of infection. It could thus be plainly seen that it is in the interests of the community, and of the public health in particular, that the two professions should work together, for each had much to learn from the other.

The Royal College were at the present time considering in what way the Fellowship degree could be made more desirable, and it was proposed that the qualification for such a degree after obtaining Membership shall be two years instead of five as formerly. There is also a regulation for a new diploma in Veterinary State Medicine, of which Prof. Delépine had made mention. He could assure Prof. Delépine there is no jealousy in this matter at all. All they wanted to do in the development of this new degree was simply for specialising purposes. This diploma can be taken twelve months after obtaining the Membership diploma. The scheme acts in attracting greater numbers with commensurate

advantages. This has been fully recognised in Germany and other Continental countries, and in America where State aid is generously dealt out for the veterinary schools. Unfortunately this country suffered for that want.

He was convinced that the President of the Board of Agriculture, Mr. Runciman, was kindly disposed to the veterinary profession. Speaking recently before the Farmers' Union, he made an important announcement with regard to the future work of his Committee when he said if a few thousand pounds were spent on the veterinary profession they might stamp out swine fever, thereby saving tens of thousands in compensation. The compensation paid in cases of swine fever amounted to something like fifty or sixty thousand pounds a year. Provision would have to be made for an efficient organised veterinary service, fully equipped for research and administrative work. The result would be a greater freedom from harmful diseases. Speaking with regard to the financial position, he said this was not satisfactory, and such a state of embarrassment should not be, especially in a country which boasts of the excellence of its live stock, and in which stock raising yields two-thirds of the total agricultural revenue. It is the duty of the State to see that adequate provision is made for purging our herds and flocks of disease, as well as safeguarding them from scourges from outside sources.

The veterinary profession is self supporting, and without substantial assistance from the National Exchequer it is not equal to undertaking the public work that belongs to it, and with which they are competent to deal. The Tuberculosis Order, he said, came into operation last May and was, in his opinion, the thin edge of the wedge, and would eventually lead to considerable activity in this disease of tuberculosis.

He wished to refer to the work done in Manchester in regard to the supply of pure milk, and mentioned that in Birmingham there are thirty herds of cattle under the supervision of the Corporation veterinary surgeon. Tuberculin is injected twice a year; the milk supply is pure, and goes to the Infirmary and other public institutions. This is a matter worthy of emulation by all our large cities and towns.

He would urge the necessity of stricter supervision, and it is only right that the veterinary surgeon should be the one appointed to undertake such work.

Mr. Woods proposed "The President." He said that fortunately for him this toast did not require many words, because they all knew the President so well. When a few years ago he advised Mr. Locke that the quickest way to obtain the confidence of his colleagues was to become grey and bald he did not expect his advice to be taken literally.

He knew of no more difficult position in which a young man could be placed than to have to succeed to a large practice carried out by a distinguished father. All at once the advice that he has been used to ceases, the few words of encouragement as to diagnosis and treatment are wanting. It is a time of very considerable anxiety to every young man, for a number of years, to have to undertake such a practice after such a father as Mr. Sam Locke. He was a man of very high ideals, and it is because the members of the Association know that the son is carrying aloft the torch handed on to him by his father that they have asked him two years in succession to act as President.

Mr. Locke, responding, felt at a loss to express his thanks for the kind words of Mr. Woods, and also to the Society for the honour conferred upon him a second time. He felt this to be a greater honour from the fact that the International Congress is to be held in London this year. He would continue to do his best to uphold the honour of the Lancashire V.M.A. In conclusion he desired to thank Mr. Brittlebank for the great assistance rendered.

"Our Guests." Mr. BRITTLEBANK, on rising to propose this toast, said that he always considered that one of the essential qualifications for any secretary was to be seen but not heard too much, but he could not deny the very great pleasure it gave him to submit this toast, particularly when he had to couple with it the name of his old friend Principal Bradley. A gathering such as theirs that evening would be but comparatively poor without the society of their many friends, and on behalf of their Association he thanked all those friends who were present for the great pleasure it had been to see them again at their festive board. The speeches that had been made that evening had reached a very high standard which he could not essay to maintain, but as their Secretary he perhaps might be allowed to depart for a moment from the subject matter of the toast. One of the previous speakers had, in a very laudatory and excellent speech, referred to the fact that in his opinion the veterinary profession was far too modest a body and did not think enough of itself. For his part he thought that a certain measure of modesty was rather to be acclaimed than otherwise, but really analysed, the measure of the so-called modesty of any corporate body was in direct ratio to their power to assert themselves. Unfortunately the veterinary profession was numerically small and financially poor, both collectively and individually, but he could assure the previous speaker that so far as their ambitions were concerned they were unbounded. As a profession they knew quite well what they wanted, and he hoped that they were generally attaining their ends, but he would respectfully suggest that what they required more than advice, is actual material assistance from those who have the power to give it. These remarks he admitted were not strictly in relation to the toast he had to propose, but the Lancashire Veterinary Medical Association, now an integral part of the National Veterinary Association, had in the past, and would in the future continue to do all in their power to advance the interests of their profession.

He would remind all present of the great part which Dr. Bradley had played in carrying through the scheme of federating the various veterinary societies of the country under the National Association. He was sure that it would prove of incalculable benefit to the profession in the years to come. Dr. Bradley had by force of character and the high standard of his work established himself in a high position in the profession, and as an old student at the New Veterinary College he was proud to see him at the head of the Royal (Dick) Veterinary College, an institution which had a great past, but he ventured to say had an even greater future under the wise government of his old friend. He submitted with great pleasure the toast coupled with the name of Dr. Bradley.

Dr. O. CHARNOCK BRADLEY, in responding to the toast of "Our Guests," said that blessings were almost daily being showered upon the veterinary profession by those in high places. Though blessings were highly appreciated, he could not help thinking that veterinary science was something like the field of Emerson's Cape Cod farmer, and stood in need of something more substantial than blessings. Veterinary science was undoubtedly moving, and moving rapidly. The goal was sometimes evident, sometimes hidden, but the fact that mattered was that they were not standing still.

"The Ladies" was proposed by Mr. TAYLOR, whose witty remarks were much enjoyed.

Mr. HOUGHTON replied, and thanked Mr. Taylor for his very kindly remarks. On behalf of the ladies, he wished to say how much they enjoyed being there, and that they sincerely hoped that the practice commenced last year of having the ladies present at their dinner would not be discontinued.

J. W. BRITTLEBANK, Hon. Sec.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, March 9, 1914
 Note.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

Foot-and-Mouth Disease.

The Department of Agriculture and Technical Instruction for Ireland on Sunday night announced that five additional cases of foot-and-mouth disease have been confirmed within the County Cork scheduled district. Two of these have occurred near Cloyne on separate farms in the occupation of one owner. Two others are located near Waterfall and Queenstown respectively, and the remaining case has occurred at Fermoy. All appear to be traceable to the same source as the earlier cases.

Prosecutions under the Tuberculosis Order.

At the County Police Court, Carlisle, on Saturday last, four local farmers were prosecuted for failing to comply with the regulations of the new Tuberculosis Order for Animals.

The first case was that of Thomas W. Wood, Tower Farm, Rickerby, who was charged with having in his possession a cow suffering from tuberculosis of the udder, and failing to give notice to the Local Authority on the 16th February.

Jonathan Scott Bowden, Chief Veterinary Inspector for the County, in his evidence stated that this cow had an indurated udder, the teat of which was slit for the purpose of allowing matter to escape. The lungs were bad, while its temperature was 103.2°. The cow was tuberculous, and this was quite apparent to any observer. On making a post-mortem examination he found that the animal was tuberculous in every internal organ. It seemed to have been suffering from tuberculosis for some six months, and the disease on the udder must have been going on for three months at least.

Cross-examined: This was a dairy cow, and the injury to the udder must have been apparent for three months; since it was in a caseated condition, and such a condition could not develop in a fortnight. Of course, it was quite feasible that the man might have passed it. Mr. Wood never was anything but open in giving information, while all his cows seemed to be well looked after. When he made his examination he thought the animals were well tended. The farmer was not asked to diagnose, but to give information to those who could.

By Mr. Main: I feel confident that the disease must have been apparent for nearly three months. The udder was enlarged, while the shape was all "lopsided," and should have attracted the owner's attention.

By Dr. Barnes: The teat was slit to allow of the escape of the broken down matter, which was evil-smelling.

Robert Craig Robinson, Veterinary Inspector, stated that he examined it and found it diseased with extensive induration of the udder, which was quite patent to the eye of the ordinary observer. The udder was quite deformed. In a post-mortem examination he found the internal organs tuberculous, and in an advanced stage. The carcass was afterwards condemned. This condition of the udder must have taken three months to develop, and was chronic.

By Mr. Main: The defendant would only cut the teat when he found that the animal was suffering.

Similar charges were brought against Jonathan Stalker, Sceughmire, Orton; John Chaplow, Scotby Shields; and John Henderson, Crookdyke, Rockliffe.

The fines and costs were as follows:—Wood, £8 5s. 8d.; Chaplow, £7 12s. 6d.; Henderson, £8 6s. 6d.; and Stalker, £3 13s. 6d. The total for the four cases was £25 18s. 2d.—*Carlisle Journal*.

* Number of bovine animals suffering from tuberculosis of the udder, tuberculosis with emaciation, or giving tuberculous milk, in respect of which notice of intention to slaughter has been received.

Rabies in India.

Bangalore, Jan. 26.

Corporal Gardiner, 44th Field Battery, who recently arrived here from Bellary, died at the station hospital last night of hydrophobia contracted, it is presumed, from the bite of his pet monkey which had been bitten by a mad dog at Bellary six months ago. Nineteen other men of the same Battery who were bitten by the same monkey were despatched to the Pasteur Institute, Coonoor, last night.

In addition to the nineteen men of the 44th Battery, fifteen others, medical officers and men, who dealt with the late Corporal Gardiner during his illness are leaving to-night for the Pasteur Institute. The deceased soldier showed symptoms of hydrophobia early on Saturday morning in barracks, and was removed to hospital where the spasms became more frequent and increasingly severe. A specialist was summoned from Poona, who performed tracheotomy. Chloroform was also administered to relieve the spasms, followed up by oxygen, but the remedies failed.—*The Statesman* (Calcutta.)

The Register R.C.V.S., 1914.

The new edition contains the revised Bye-laws as passed by the Council last year, together with the draft Regulations for the proposed new Diploma in Veterinary State Medicine, and the new Regulations for the Fellowship Degree (p. 79), also the revised Syllabus for the Professional Examinations (p. 87).

In addition to the extracts from Acts and Orders published in previous editions, the Tuberculosis Order, 1913, is given—a very useful addition for country practitioners.

Among minor improvements are noted a list of abbreviations employed in the Register of Members (p. 130) and the list of "Existing Practitioners" (p. 371) has been reset in a more readable form. The number of the latter is reduced from 218 to 188—the most marked reduction for several years past. The number of members has fallen from 3441 to 3408. This represents a total reduction of registered veterinary surgeons of 63.

As in previous issues, the Registrar calls attention to the fact that 24 members have omitted to supply him with their change of address. A list of the delinquents is given at p. 309, with the warning that their names will be removed unless their address is received before the end of the year.

The book contains, as in recent issues, Calendar, Acts, Charters, Lists of Officers, Council, Examiners, Fellows, Honorary Associates, and Members; and in appendices, lists of schools, prizes, examination questions, regulations for admission to the Government services, annual report, 1913.

Price 3s. 6d. post free from the offices of the College.

Cossack Horses.

Cossack horses of a good type are bred in large numbers—and the work of breeding them seems to pay—in the district of Turkistan, and they are extensively used for military purposes. History affirms that they originate from the wild Tartary horses "found in countless thousands on the edges of vast deserts." Some mares of this class have lately been bought for Germany, and will probably be put to thoroughbred sires; it is hoped to obtain as the result horses suitable for the light cavalry, possessing some speed and great stamina, whilst being as tough and game as were their wild, unshod progenitors. Also imported into Germany is a Turkoman sire that has never been shod. His hoofs are described as never having needed protection of any kind, being naturally as hard as iron.

One of the most noted experimental animal breeders in Russia is M. Falz-Fein, who has an enormous estate, where he produces some extraordinary results. He has immense numbers of horses, cattle, camels, antelopes, sheep, zebras, and, in fact, almost every animal that can be crossed for the purpose of investigation and study, the object being to discover what can be usefully done in that way.—*Live Stock Journal*.

The American V.M.A. and the International Congress.

Our cousins across the water are making arrangements for an Official Tour of Europe in connection with the Congress, and have issued an attractive itinerary.

The tour leaves New York June 13th: arrives New York August 22nd.

The Committee consists of Dr. L. VAN ES, Fargo North Dakota; Dr. ALEX. LIAUTARD, Paris; Dr. J. R. MOHLER, Washington, District of Columbia; Dr. V. A.,

MOORE, Ithaca, New York; Dr. W. H. DALRYMPLE, Baton Rouge, Louisiana; Dr. PAUL FISCHER, Columbus Ohio. Under the direction of Dr. ADOLPH EICHORN.

The management is in the hands of the Bureau of University Travel, Boston, Mass.

The circular says: "The fiftieth anniversary of the first International Veterinary Congress is to meet in London during the coming summer. A special effort is being made to furnish a program replete with the best in possession of the veterinary profession and make it a fitting semi-centennial of fifty years of progress. American veterinarians should make every possible effort to attend this meeting. It is very probable that the American Veterinary Association will not hold its regular annual meeting in September, as has been the custom the past few years, but it will probably meet in New Orleans during the week of the holidays. This will give the members an especial opportunity for attending both meetings." It is signed by C. J. MARSHALL, President American V.M.A.

The party is timed to leave New York June 13, arrive Antwerp June 22. Where more than one day is to be spent we have indicated by figures.

BRUSSELS (2 days), Veterinary College and municipal abattoirs. Experimental Station and Agricultural School of Gembloux the largest and best in Belgium; PARIS (4), The famous Veterinary School at Alfort. The Pasteur Institute and laboratories. Abattoirs and stockyards of La Villette; VERSAILLES; BERN (2), Serum Institute of Bern, City sights; INTERLAKEN; LUCERNE RIGI; ZURICH, Veterinary College, City abattoir; ST. GOTHARD PASS; MILAN (2), Veterinary College, and abattoirs; VENICE; FIUME; MEZÖHEGYES, One of the best government breeding farms of thoroughbred stock in the world; BUDAPEST (2), Municipal abattoirs, Veterinary College, Hog Cholera Serum Institute; KISBERBARBOLNA, Highest type of Hungarian livestock; VIENNA (3), Veterinary College, Hygienic Institute, Abattoirs and stockyards; DRESDEN (3), Finest municipal abattoirs and stockyards in the world, Veterinary College; LEIPSI, Veterinary Institute under direction of Prof. Eber, abattoir and stockyard; BERLIN (4), Veterinary College, abattoirs and stockyards, German Serum Society, Imperial Board of Health Laboratories at Gross Lichterfelde; HANNOVER, Veterinary College, abattoirs and stockyards; UTRECHT (2), Veterinary College and University; AMSTERDAM; ROTTERDAM, Government Serum Institute; LEYDEN, Abattoir and Holstein cattle; CAMBRIDGE; LONDON (6), The International Veterinary Congress; EDINBURGH (2) Veterinary College; THE TROSSACHS; GLASGOW, Municipal abattoirs and stockyards; LIVERPOOL; BOSTON.

The price of the tour is 595 dols.

Special sight-seeing programs will be arranged in the cities visited for the entertainment of the ladies of the party.

MR. MOND ON TUBERCULOSIS IN COWS.

Dear Sir,

Your condemnation of Mr. Mond for expressing his views on tuberculosis, leaves out of account the fact that it has never yet been definitely proved that any human being has been infected by the consumption of cow's milk; that it is difficult to infect bovines with human bacilli; that the experiments by subcutaneous, intra-venous and intra-peritoneal injection of vast quantities of virulent sputum often failed; that some subjects were poisoned but not infected with tuberculosis; that some lesions proved retrogressive although this virulent material was employed, and that none were infected by natural means.

Neither Koch nor anyone else who has studied the subject would say that a dentition abrasion in an infant's mouth might not afford an entrance for a stray bacillus, but what are the chances? Surely the available statistics give the answer! I do not think it will be denied that three times as much cows milk is consumed by infants to-day as was taken by a previous generation whose mothers recognised their duty, and it cannot be denied that the returns of deaths from tuberculosis have fallen by fifty per cent. If the cow, as often asserted without any evidence whatever, is the chief cause of tuberculosis in human beings, then we ought to have three times as many cases, instead of fifty per cent. less.

HAROLD LEENEY,

[Quite so. But apparently we differ from Mr. Leeney as to the suitability of such statements to the audience at Knutsford.]

ERRATA, pp. 486: 487.

On page 486, 2nd column, first sentence under "Sarcopic Mange in the Dog," in smaller type, 3rd line, Acariasis should read *Otacariasis*.

On page 487, 1st col., under Sarcopic Notodres, 15th line, in the sentence, The eggs are '1 m.m. long and 0.7 mm. broad, should read '0.7 mm. broad.

On page 487, 2nd col., 21st line, "Over these areas the skin," should read *the coat*.

On page 487, 2nd col., under "Development of the Sarcopes," in line 12, "vary from 19 to 40," should read 10 to 40.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1341.

MARCH 21, 1914.

VOL. XXVI.

TOXICOLOGY.

The profession could do with more such papers as that upon castor seed poisoning which Prof. Lander has just given to the Central Society. In itself, the paper adds a little to our knowledge of one poison. More than that, it may induce practitioners to take an increased interest in toxicology. Some are perhaps disposed to neglect it, but there are not many subjects which better deserve attention from clinicians.

Prof. Lander said "Although recorded cases in the veterinary literature are very few, cases of castor seed poisoning may, and do, occur from time to time." The words might be applied with equal truth to a great many other vegetable poisons, and some mineral ones. We all know the diagnostic difficulties which so frequently attend cases of poisoning in practice—difficulties chiefly arising from the indistinctive character of the symptoms. In most cases the symptoms, however acute they may be, do not conclusively indicate poisoning at all, and usually they do not even suggest the exact poison concerned. Unless there are some circumstances in the case which arouse and support suspicion, it is quite possible for either accidental or malicious poisoning to occur unrecognised; and it is probable that both do so occur more frequently than we suppose.

Considering these difficulties, and the great variety of substances that may be toxic to animals, it is clear that no clinician can hope to ever attain more than a comparatively fragmentary and imperfect knowledge of toxicology for guidance in his practice.

The subject will always include some of the most difficult cases met with in our everyday work, and therefore a toxicological paper by an expert cannot fail to be helpful. For obvious reasons, such papers seldom excite brisk discussion, but that does not detract from their special value.

THE SUPPLY OF VETERINARY PRACTITIONERS.

There are now only 3408 members on our Register. How many of them are engaged in independent private practice in this kingdom? Probably no one could answer the question exactly, but a little thought suggests that the number must be surprisingly small. Some hundreds are abroad. Many at home are in the public services, or retained by various bodies; some are assistants; and some not in practice at all. A careful analysis of the Register, if it could be made, might indicate that the national supply of private practitioners is already beginning to fall short of the demand.

LUNG PUNCTURE IN PULMONARY TUBERCULOSIS AN AID TO DIAGNOSIS.

The more methods the clinician can bring to his assistance, speaking generally, the better is he in a position to eliminate the risk of error, the result being a more accurate diagnosis.

In pulmonary tuberculosis to obtain a positive diagnosis the tubercle bacilli must be identified. This, as we all know, in some cases is not an easy matter owing to the fact that the *materies morbi* is not always obtainable through the usual channels, and in addition, when it is obtained, it runs the risk of becoming contaminated with other alien acid-fast bacteria which simulate in appearance Koch's bacillus, thereby tending to lead to errors in diagnosis. Realising these difficulties in dealing with non-expectorating animals it occurred to me that it might be expedient to aspirate the *materies morbi* from the lung directly through the chest wall. In this way an excellent method is adopted to detain the germ-laden material which has had the risk of contamination, by acid-fast bacteria, reduced to a minimum. It is scarcely necessary, however, to point out that the same difficulty is here encountered which one meets with in collecting material from other organs, *i.e.* the bacilli may be so few in number as to escape the most diligent microscopical investigation, or they may be absent from that particular collection altogether.

Centrifugalising the material will facilitate the demonstration of the bacilli in the former instance, while in the latter several lung punctures may be carried out in the same subject at the same time.

Modus operandi. A careful physical examination (auscultation and percussion) should be made of the most prominently diseased area and located. The hair should be clipped over this region and the skin well scrubbed with strong tincture of iodine. At the point of entrance of the needle a drop of pure lysol is now applied. The animal is then caught by the nose and horns and held by an attendant. Five to ten cc. of sterile broth or water is taken up and the needle of the aspirator then plunged boldly into the lung parenchyma between the ribs, taking care the seat of puncture is as far removed from the posterior border of the rib as possible, the object being to evade injury of the intercostal artery and vein. The needle having been driven home the fluid is now steadily injected, and after the elapse of about a minute, aspirated. It is impossible to abstract all the fluid which has been injected, nor is this even necessary. The needle may have penetrated a small bronchi or pulmonary vessel, either of which are capable drainage channels. If it

enters a purulent infective cyst and the pus is fairly liquid, little or none of the infected fluid is here aspirated, the aspirate being almost entirely composed of the morbid material.

If a pulmonary blood vessel has been struck, the collection may be made up wholly of blood which will offer, as a rule, in itself a small chance of contributing to an accurate diagnosis. This should be discarded, and another area explored. In other cases the aspirate medium may present a sero-sanguinous appearance, while held in suspension, is often found lung *debris*. In some instances the lung tissues appear to block the point of the needle, thwarting all aspiratory efforts. Simple rotation of the needle will sometimes overcome this difficulty; should this fail, however, I do not hesitate to move the needle laterally with the view of breaking down part of the lung structure, and re-aspirate. The material thus collected should then be centrifugalised in fine tapering tubes, and stained by carbol fuchsin, etc., in the usual way.

Case I.—A shorthorn cow suffering from catarrhal pneumonia, had three punctures, two in the left and one in the right lung, and the three resultant fluids mixed, centrifugalised and examined. Tubercle bacilli were found, the field showing three small collections and two distinct isolated bacilli.

Case II.—Shorthorn cow, recently calved, showing pneumonic symptoms. An area of dullness in the lower third of the right lung was detected, and a puncture was made between the 8th and 9th ribs and about 10 c.c. of thick pus aspirated. From this I was able to demonstrate a fair number of tubercle bacilli.

Case III.—Devon steer, two years old, in good condition but suffering from a more or less persistent cough and emphysematous respiration. An area of dullness was detected on the right lung, and aspiration produced a sanguino-purulent material. From this no tubercle bacilli were detected. Seven days later lung puncture was again performed, 5 c.c. were again aspirated two inches from the seat of the original puncture, while the left lung, showing a distinct rhoncus, was punctured and material collected. The two collections mixed, centrifugalised, and specimen stained, when examined revealed the presence of many tubercle bacilli.

Case IV.—Devon bull, with persistent cough and showing symptoms of broncho-pneumonia. Four punctures were made, two in each lung, but no morbid material could be aspirated. I presume the needle was too short, necessitating the procuring of a longer needle.

Some few days later a puncture on each lung was made, a semi-sanguinous fluid, somewhat chocolate looking in colour, with solid lung particles in suspension was aspirated, the fluid treated in the usual way, and although four smears were made the results were negative.

Case V.—Shorthorn cow, with a healthy history and in good condition, had calved four days previously, and was suffering from septic retention of the afterbirth. This was removed and the womb irrigated. Two days later pronounced pneumonic

symptoms set in, probably due to septic infection. Two punctures in each lung were performed, with the result that a sanguinous brown-looking aspirate was obtained. From this three slides were examined with negative results. The animal died three days later. A post-mortem examination was made, the mediastinal and prepectoral glands were enormously enlarged and caseating. Scrapings from these revealed the tubercle bacilli in great abundance.

CONCLUSIONS.

I consider lung puncture is a most valuable aid to the diagnosis of pulmonary tuberculosis. It is a simple operation, and if carried out with antiseptic precautions, carries with it no risky sequelæ. I have, in addition to the cases above related, punctured the lungs of 12 equines and four bovines without any untoward results. In the case of one horse I have made nine punctures in 24 hours, all of these with the object of making vaccines.

In the five cases recorded here, each animal was in good condition, and in the first three cases where a positive diagnosis was made, there were pronounced pulmonary symptoms, none of which, however, the most experienced clinician could interpret as belonging specially to tuberculosis. I therefore consider lung puncture a valuable asset in obscure and non-suspicious cases, as well as in those showing pronounced tubercular symptoms and lesions. Needless to add, the aspirator must be sterilised before use. I prefer the injection of broth to that of water, the former has more consistency, and if a bacterial culture is required, an excellent nutrient medium is at once obtained. When the puncture is performed for diagnostic purposes only, sterile water does quite well. In both cases the fluid media should be raised to blood heat before injection.

From post-mortems I have made, I have noted that the entrance of the needle through the parietal and visceral pleura is indicated by a small scar, without any signs of a radiating pleurisy or even adhesions.

In the lungs I have seen at the seat of puncture sometimes a small blood clot, and a slight diffused discolouration of the tissues where the fluid media has penetrated, but beyond these there is nothing to show the lung tissue had been tampered with from without.

WM. SCOTT, F.R.C.V.S., F.R.M.S.

Bridgwater.

ABSTRACTS FROM FOREIGN JOURNALS

AUTO-SERO-THERAPY IN VETERINARY OPHTHALMOLOGY.

Pruneau, an Army veterinary surgeon, has published (*Recueil de Méd. Vét. d'Alfort*) an article upon this subject. He has seen auto-sero-therapy applied with very good results in cases of iritis and phlyctenular kerato-conjunctivitis in human ophthalmology, and therefore tried it in a case of specific ophthalmia in a horse, with most successful results.

The affected horse had violent conjunctivitis and photophobia. Lachrymation and hypotonus were present. The anterior chamber of the eye was opaque, and contained a fairly abundant collection of pus. The iris was opaque and dull, the ciliary region was sensitive, and the background of the eye could not be illuminated.

The horse received a first injection of 3 c.c. of serum. Twenty-four hours later there was no more lachrymation, the photophobia had almost wholly disappeared, and it was possible to illuminate the background of the eye. The pupil was still opaque and somewhat suffused, but the vessels proceeding from it were distinctly visible. The day after this (thus two days after the first dose) the horse received a second 3 c.c. of serum. Two days later he appeared cured, the pus in the anterior chamber of the eye was insignificant, the iris reacted to light and became dilated upon the injection of cocaine, so that it could be seen that no synechia were present.

The author has also applied this treatment in the case of another horse, suffering from pseudo-membranous conjunctivitis. Complete recovery was obtained after two days.

The technique of the treatment is as follows:—

(1) Blood is withdrawn from a superficial vessel by means of a 20 c.c. hypodermic syringe, and is placed in a small wide-necked flask which has previously been subjected to dry sterilisation and hermetically sealed. The flask is then put into a dry place.

(2) Twelve hours after the withdrawal of the blood, it has coagulated and a quantity of serum sufficient for the treatment has exuded from the coagulum. It is better, however, to postpone treatment until twenty-four hours have elapsed. About 3 c.c. to 4 c.c. of the serum is then drawn up with an aseptic syringe, and the flask is closed very carefully. The flask can then be kept for another three or four days in a cool place.

(3) The affected eye is anaesthetised with five or six drops of a sterilised 4 per cent. solution of cocaine, and then washed with lukewarm sterilised physiological salt solution.

Whether the injection can be undertaken upon the standing animal or whether casting is necessary depends upon the degree of the horse's irritability and the perfection of the anaesthesia which has been attained.

(4) The upper eyelid is drawn well upwards: and the needle of the syringe is inserted under the conjunctiva of the eyeball, as far as possible from the edge of the cornea. About 3 c.c. of serum is then injected quite slowly. The resultant oedematous swelling is absorbed in twelve hours at the latest.

(5) The needle is withdrawn by a sudden movement, and the eye is washed with physiological salt solution. A second injection may quite well be given twenty-four hours after the first one.—*Berl. Tier. Woch.*

[The technique of this treatment should be well within the powers of most practitioners.—*Transl.*

MELANOTIC SARCOMA OF A DIGIT WITH CUTANEOUS AND POLYVISCERAL METASTASES IN A DOG.

Samson records (*Journal de Méd. Vét. et de Zoot.*) the case of a dog, five years old, which suddenly became very lame on the left fore limb, and at the same time showed a very distinct tumefaction of the extremity of the internal digit of the same limb. This was treated by baths, poultices, and by point-firing the swelling. The condition became worse, and four months later the animal was walking upon three legs. He suffered a good deal, and lost flesh daily. By that time the internal digit was very inflamed; and its extremity bore a swelling the size of a nut, which was black, malignant-looking, and pierced at its centre by a suppurating cavity.

Samson advised removal of the digit, and the operation was performed with complete success. The resultant wound healed in about a fortnight, and the bearing of the limb soon became normal. The dog, therefore, seemed to be cured.

Eight months later, he was again brought for examination. His intervening history had been good; but he now showed a tumour the size of the fist, uniformly hard and insensitive, situated at the base of the neck in front of the left shoulder, immediately at the entrance of the thorax. This was subjected to both internal and external treatment with iodine. About a fortnight later, the tumour had softened at one point. This was punctured, giving exit to a very abundant black pus. After the wound was cleansed, an examination of its interior showed a mammilated, filamentous, and perfectly black tumour.

Antiseptic treatment did not cause the abscess to close. The tumour augmented in volume, and others appeared at various points—upon the skin, in the region of the right flank, and in the muscles of the abdominal wall. Evidently the case was one of a melanotic tumour undergoing generalisation.

The dog now again lost condition, became dull, completely lost his appetite. Despite treatment by digitalis, iodides, and electrargol, he became worse, and it was finally decided to destroy him.

Post-mortem, it was found that the generalisation of the tumour was very advanced. All the organs were invaded, except the liver.

Histological examination of the metastatic growths, carried out by Prof. Ball, showed that the tumour was a sarcoma of mixed round and spindle celled type.—(*Annales de Méd. Vét.*)

HÆMORRHOIDS IN A HORSE.

Michael Schmidt, a Hungarian veterinary surgeon, records (*Allatorvosi Lapok*) the case of a nine-year-old brown gelding to which he was called. The history was that during defecation the horse groaned painfully, and at the same time a large swelling protruded from the rectum. The faeces were often covered with bloody mucus.

Upon manual exploration, the author discovered a jelly-like warm swelling the size of an apple on the dorsal wall of the rectum. After the administration of a clyster, the swelling was extruded from

the rectum with the ejected water; and it was seen that its surface was dark red, and showed various lacerations and granulations.

The swelling was ligatured with catgut, and laxatives and green food were ordered. On this treatment the horse made a complete recovery.

Such varicose swellings of the rectal wall are rarer in animals than in man, in consequence of the different position, which makes circulatory stasis less common in animals than in man.—(*Berliner Tier. Woch.*)

THE CANINE PIROPLASMOSES OF EUROPE AND AFRICA.

Laveran and Nattan-Larier report (*Annales de l'Institut Pasteur*) the results they have obtained in the comparative inoculation with virus of canine piroplasmoses of French and African origin. They conclude that the two diseases produced are identical; and no means of differentiating between them exists either in their symptoms, their lesions, or their evolution. It can only be said that the African virus is more active than the French one; because the African virus destroyed 17 dogs out of 19 inoculated with it, while only 15 dogs died out of 23 inoculated with the French virus. No difference exists in the morphology of the two piroplasms.

On the other hand, a study of the resistance which dogs which have been immunised against one parasite offer against the other, shows distinct differences. Seven dogs which had been immunised against the French piroplasm all became infected when inoculated with the African one, and six of them died. Two dogs which had been immunised against the African piroplasm were infected by the French one; but the infection was only slight, and both animals recovered.

The authors therefore conclude that *Piroplasma canis* of Europe and *P. canis* of Africa, are, if not two distinct species, at least two clearly distinct varieties.—(*Annales de Méd. Vét.*)

W. R. C.

YORKSHIRE VETERINARY MEDICAL SOCIETY. [NATIONAL V.M.A.—NORTHERN BRANCH].

The annual meeting was held at the Hotel Metropole, Leeds, on Friday, the 30th January, at 4 p.m. Mr. McKinna, of Huddersfield, took the chair in the unavoidable absence through illness of Mr. J. Abson, the President, and the following members were present:—Messrs. S. Wharam, A. W. Mason, H. G. Bowes, and A. McCarmick, Leeds; Geo. Whitehead, Batley; P. Deighton, Selby; H. M. Holland, Keighley; H. Pollard, Wakefield; Percy Abson, Doncaster; J. A. Hodgman, Barnsley; W. Edmondson, Harrogate; C. Pitts, Bradford; F. W. Pawlett, York; J. W. Lazenby, Tadcaster; and J. Clarkson, Hon. Sec., Garforth.

Visitors: Messrs. F. W. Garnett, Windermere; Percy Carter, Bradford; J. H. Carter, Burnley; and Prof. O. C. Bradley, Edinburgh.

The minutes of the previous meeting were taken as read.

On the proposition of the Chairman, seconded by Mr. Wharam, it was decided to send a telegram of sympathy

to the absent President, sympathising with him in his relapse and expressing the meeting's sincere wishes for his speedy recovery.

The SECRETARY stated that a communication had been received from the Sanitary Institute regarding the next Congress to be held at Blackpool in July, and asking whether the Society would join the Congress.

The CHAIRMAN pointed out that their own International Congress would shortly be held, and that of course would overshadow all other matters in the near future.

After some discussion the matter was dropped, and no motion was proposed.

The SECRETARY stated he had received a postcard from Mr. Pratt who had been very seriously ill for some six months past, to the effect that he was better. Mr. Pratt, continued the Secretary, was one of the original founders of the Society, he had presented them with a unique set of pathological specimens and horse-shoes, and was generally held in considerable esteem by the profession. He thought every one present would be very glad to hear of Mr. Pratt's improvement in health.

Mr. S. WHARAM asked why the present meeting was not held in the usual room of the hotel where Mr. Pratt's specimens were exhibited. It was explained the reason was that it was thought that room was not large enough for the annual meeting.

Messrs. S. B. VINE, Settle; P. THEXTON, Pontefract; and E. J. NICHOLSON, Bridlington, were elected as members of the Society on the proposition of the Chairman, seconded by Mr. H. G. Bowes, the latter stating that he had known Mr. Nicholson as a student and felt he would make an excellent member of the Society.

The CHAIRMAN referred to the recent loss the Society has sustained in its list of Honorary Associates through the death of Mr. Hunting, and submitted the names of Dr. Bradley of the Royal Dick College of Glasgow, and Mr. Garnett of Windermere, for enrolment on the Honorary Associates list. With reference to Dr. Bradley, he said that when they took into account his work on comparative anatomy and the work he had done for the profession as a whole, they must feel they were not only honouring him by asking him to allow his name to be enrolled on the list of Associates, but they were also honouring themselves by so doing. Mr. Garnett also was a distinguished member of the profession, and had done a large amount of work in the Council in that thorough manner that characterised everything he took in hand.

The SECRETARY said he wished to associate himself with the remarks of the Chairman. In Dr. Bradley and Mr. Garnett they had two men who were fully entitled to any honour that any society might wish to confer upon them. Mr. Garnett was, he thought he might say, the worker of the profession as regards scientific work, in which he had accomplished a large amount of original research; and everybody knew or should know of the time and labour he had expended in connection with the Council, and in particular with the Parliamentary Committee. At the time of Mr. Garnett's election to that Committee it had held no meeting for something like seven years, but Mr. Garnett had raised it from that position to be the most important Committee of the Council. Dr. Bradley had also done a great amount of work in connection with the amalgamation of the various societies into the National Society.

On being put from the chair the motion was carried unanimously.

Mr. GARNETT briefly thanked the members for the honour conferred upon him, and assured them that any work he had done had been performed simply for the love he entertained for the profession itself.

REPORT OF THE COUNCIL.

The SECRETARY stated that at the last meeting the matter as to the day on which ordinary meetings should be held, after being fully discussed, was put to the vote, with the result that eleven members voted for Friday as the day for holding the meetings, seven for Thursday, and one for Monday. The question was afterwards referred to the Council for consideration, but that body came to the conclusion that it would be inadvisable to change the day, as, if any change were made, the effect might be that more members might find it difficult to attend than was the case at the present time. The recommendation of the Council therefore was that the pay should not be changed.

THE HUNTING FUND.

The CHAIRMAN introduced the question of the the Memorial Fund which was being raised in remembrance of the late Mr. Hunting, than whom no man, he said, since the profession was instituted had better deserved its gratitude. The Council had recommended that a sum of three guineas should be voted to this purpose, and he wished to know if the meeting endorsed that recommendation. [The sum of three guineas was voted to the fund].

INTERESTING CASES.

Mr. H. M. HOLLAND, of Keighley, exhibited a preserved specimen of a large testicle which he had taken from the abdomen of a dog six months ago. When called in to attend the case he thought the dog—a bull dog of the Rodney Stone strain—was suffering from dropsy, and was informed by the owner that whenever the dog made water, he either just previously or just afterwards ejected a small amount of pus-like matter.

The dog was about 2½ years old, but had only had one testicle present in the scrotum during life, and this was a very small one, no bigger than an ordinary filbert nut. He (Mr. Holland) endeavoured to get some fluid away, but was only able to get about a gill; he then felt the presence of the body more distinctly in the abdomen. He thereupon advised the owner to have the animal destroyed, considering it a case of a malignant growth. The dog died, however, before the owner gave him permission to destroy it, and when a post-mortem was made the enlarged testicle which weighed two or three pounds was found in the abdomen. The specimen showed just one half of the testicle. The cysts were full of a gelatinous matter.

The specimen was handed round for inspection, and the Chairman characterised it as a most interesting and remarkable case.

Mr. P. DEIGHTON, of Selby, gave an account of a valuable hunter he had attended for laryngitis whose temperature when he was called in was 106°. During his treatment of the animal, which lasted two or three weeks, there was the greatest difficulty in getting any medicine into the horse at all. As soon as his head was up he began to cough and a ball could not be given. After three weeks treatment, Mr. Deighton called in the services of Mr. Mason of Leeds, but when the latter went to see the horse it was improving, was out, and progressing very well. Mr. Mason suggested blistering the horse's larynx, with the idea of preventing his being a "roarer" after the illness. That was on the Wednesday; on the following Sunday, however, the horse began with colic, and when Mr. Deighton went to see him he was in a very bad state, rolling about, with a temperature of 105°. After spending a long time with the animal endeavouring to relieve its pain, Mr. Deighton left him for about an hour, and when he returned he found what he characterised as the clearest case he had ever seen of purpura hæmorrhagica. There was a well marked line, and his legs were swollen tremend-

ously. The following morning the animal died. On making a post-mortem examination he found all the organs were slightly congested; the liver, which was a very small one, being so rotten that it could not be lifted up. Mr. Deighton remarked that the horse had been coaxed to take Molassine meal in its corn, etc.

Mr. WHARAM asked whether it was suggested that Molassine meal had anything to do with the horse's illness or condition.

Mr. DEIGHTON: When I saw the condition of the liver I thought that might have something to do with it.

Mr. MASON, in referring to the case, said he had rather wondered in the first instance why his friend Mr. Deighton had called in a second opinion, but when he went into the case he understood the peculiar position his friend was in. Here was a valuable hunter which would not eat at all, and yet when he (Mr. Mason) arrived he had a normal temperature and was practically in the pink of condition for a horse recovering from what he might term a low fever. He attributed the animal's collapse to the fact that he was kept in a box of a stable at the end of three stalls, and he thought that was a very unsatisfactory place to keep a horse in when off his food, and in a low state of fever. Had the horse been removed he thought he might have recovered eventually.

Mr. WHARAM asked whether the horse had been hunted during the season or what he had done during the summer, and Mr. Deighton's reply was that he had not been hunted, and had been kept in the box in the summer, but had been shown at several agricultural shows, as his owner wanted to sell him. Besides Molassine meal, the animal had been given Henry's powders, but there were no more powders or Molassine meal anywhere in the place now.

Mr. McCARMICK mentioned a case he had had, somewhat similar to Mr. Deighton's, of a horse which was suffering from catarrh, and there was a great amount of discharge for three weeks. When he went to see the animal he found a well-marked case of purpura hæmorrhagica, with a temperature of 105°. He got the horse into slings at once, gave two injections, and put him on a diet. At the present time the animal was very much better.

Mr. J. H. CARTER said Mr. Holland's case had recalled to his mind a case several years ago, where a dog after urinating gave a copious discharge of pus. After being under his treatment for two or three weeks the animal had to be destroyed, and the post-mortem examination revealed an enormous cyst about the size of a large coconut.

Mr. PERCY CARTER mentioned a case of an enlarged testicle in a dog he had treated only a day or two before, which he said was very similar to Mr. Holland's case, though the testicle in his case was very much smaller, only weighing 11½ ounces. The dog was a beautiful collie about 14 years old, so he was informed, though to look at it did not appear to be more than seven or eight years old, and he found no second testicle. On examination he found tumefaction in the region of the scrotum entirely occupying one side of the groin, and thinking it was some form of tumour he advised the animal's destruction. On a post-mortem he found the large testicle, which he produced for the inspection of the members. Mr. Carter added that the dog's health had not been affected up to that time, and there was not much fluid when the testicle was taken away.

Mr. GARNETT exhibited a bottle of fully developed worms, which he said had been collected from one expulsion at the coughing of a young heifer which he was treating along with others in August. He thought the case was very remarkable in view of the fact that it had always been his experience that worms began to come

about the end of September, or October and November. As this happened at the beginning of August the worms must have been taken up some time in May, and the development of them must have been very rapid indeed. They were all quite adult worms. About 14 of the heifers, which were about six months old, were affected, and one died.

The CHAIRMAN asked Mr. Garnett if he had treated the heifers by intratracheal injection, and the reply was that he had done so.

Mr. CLARKSON referred to a parturition case he had attended where the owner had complained to him that he had been very much troubled with abortion among his cattle, and had thought that the cow in question was aborting four months before, but apparently she had not. Mr. Clarkson's attention was called to the cleansing, which was a tremendous one, and on looking at it he found an imperfectly developed calf of probably four or five months; one calf was alive and the other arrested in his development. He thought this very unusual, because as a rule if one died the remainder came away, but in this instance the cow had carried the other calf completely through.

The CHAIRMAN expressed great satisfaction at the account of the interesting cases they had listened to, and hoped at future meetings this item would not be omitted from the agenda.

Mr. WHITEHEAD proposed a hearty vote of thanks to the gentlemen who had brought the interesting specimens and given the accounts they had listened to with so much pleasure. Mr. Wharam seconded the vote, which was carried unanimously.

Mr. WHARAM said he would like to see the number of instruments purchased by the Society increased. He thought if this were done the usefulness of the Society would be augmented, he proposed that the matter should be referred to the Council.

The SECRETARY pointed out that the same proposition had been made at the last quarterly meeting, and in due course it had come before the Council meeting, but in the absence of Mr. Wharam it had been deferred.

Mr. WHARAM then raised the point of the title of the Association. He thought the title of the Society should be "The Yorkshire Veterinary Society," and that the appellation "medical" should be dropped. He could not see that they gained anything by trenching on the medical profession, and he should like to hear an expression of opinion on the matter from the members there present.

The SECRETARY remarked that the same question had been discussed by the Society before, but he thought it might usefully be brought before the members again, and if Mr. Wharam would give due notice it would be placed on the agenda for consideration at a future meeting.

Mr. POLLARD proposed a vote of thanks to Mr. McKinna for so well fulfilling the office of Chairman at short notice. Mr. Clarkson seconded, and this was carried.

THE ANNUAL DINNER.

At the dinner which followed Mr. J. McKinna (Huddersfield) again presided in the absence of Mr. J. Abson, President. Among the guests were Mr. J. H. Carter, of Burnley, (President of the Royal College of Veterinary Surgeons), Dr. O. C. Bradley (Royal Dick Vet. Coll., Edinburgh); Dr. Arthur Dennison (Chairman of the Sanitary Committee of the Leeds Corporation), Dr. Angus (Assistant M.O.H. for Leeds), Mr. F. W. Garnett, Windermere, and Mr. Thomas, Leeds.

After the usual loyal toasts had been drunk with musical honours,

Dr. ANGUS proposed the toast of "The Veterinary Profession," and said he welcomed that opportunity of

stating how very glad he was as representing the medical profession to meet the sister profession of veterinary surgeons. The veterinary profession, he thought, was more fortunate than the medical profession in the fact that they had the advantage of the one portal system. He regretted, however, that the importance of the veterinary profession to the country at large had not been sufficiently recognised by Government departments and those who held the power of opening the purse strings. He understood a movement was on foot to have the veterinary College incorporated, and he wished them every success in their endeavours in that direction. They in the medical profession would only have been too glad to have been in the position of an incorporated society during the perilous times the profession had passed through in recent years through the introduction of the National Insurance Act. When a society was incorporated it had a much stronger hold upon its individual members, and from that point of view alone it was a desirable thing. He had been informed of the forthcoming International Congress of Veterinary Medicine to be held in London this year, and he wished them every success in their meetings. Such congresses were of the greatest importance in disseminating abroad the advances of medicine and surgery in every country, and he was sure the delegates from other countries would depart with a very high opinion of the veterinary profession in Great Britain. As representing the public health aspect of the question, he should like to see every bond which the medical and veterinary professions had between them still strengthened, as the trend of legislation was more and more in the direction of dealing with matters which concerned them both. The Tuberculosis Order was one instance where, unless the medical and veterinary professions worked hand in hand, very little success would be likely to be attained, and the same thing would hold true, he presumed, when the Milk and Dairies Bill became law. He deplored the lack of endowment and philanthropic encouragement to veterinary science, and he thought philanthropists might profitably devote some part of their gifts to endowing veterinary research work. The question of swine fever was a matter that they had to deal with as a public health department, and they heard a great deal about the woes of pig keepers under the ban of a terrible Board of Agriculture. From what he had read in the daily papers of speeches made at the annual dinners of butchers, meat traders, and so on, it would appear that the Board of Agriculture's methods of treating disease were simply extraordinary. On inquiry from experts in the veterinary profession, however, it would seem that the serum treatment was not so very efficacious as the butchers would have them believe. It was in the direction of investigating the efficacy of serums and vaccines that the Development Fund was going to be devoted and grants made from it to the veterinary profession, and he, for one, was very glad to hear it. Finally, he should like to say that if the veterinary profession were as successful in their treatment of their patients as they were in the treatment of their guests the farmers would live to bless them.

Mr. J. H. CARTER, in responding to the toast, referred to the pleasure he felt at being again invited to be present at the annual meeting and dinner of the Yorkshire Veterinary Society. The Yorkshire Society was one of the most important in the country, and one of the oldest established, and he was proud to know that his father was one of its founders. When he himself obtained his diploma he joined the Society, and it was not until his removal to Lancashire that he had had to sever his membership with the Yorkshire Society. Although the position of the Royal College of Veterinary Surgeons was not encouraging from a financial point of view, he thought there was never a more encouraging future for the veterinary profession than

there was to-day. If the advent of motor cars had had the effect of driving the horse from the streets to some extent, yet on the other hand it provided considerably more accidents, which all meant grist to the mill. The Bill in connection with tuberculosis proposed by the Board of Agriculture in May last should also prove lucrative to the veterinary profession. With regard to the serum treatment of swine fever, the results had not been altogether reassuring on the Continent and America, but that same method was being adopted at the present time on certain farms in this country. With regard to other diseases, such as foot-and-mouth disease, pleuro-pneumonia, and rabies, no other country in the world was so free from those diseases as we in Great Britain were. He thought that spoke well for the veterinary profession of this country. He had recently read in the newspapers that Mr. Runciman had stated he had been considering a scheme which he hoped to put before the Development Commission for strengthening the veterinary profession, and added that it was absolutely necessary that further assistance should be given from the National Fund towards the education of veterinary surgeons. As to the future of the profession he thought that they might possibly be taken over by the powers that be and become paid servants of the State, like another profession he could name. God forbid that we should ever be looked upon as a down trodden profession, robbed of our independence, and all this by the ruthless ravages of rapacious radicalism. The raising of the standard of stock was bound to have the effect of rendering the work of the veterinary surgeon more lucrative. With regard to the International Congress to take place in this country this year he hoped every member of the profession would liberally subscribe towards the fund that had been instituted, because gentlemen from every part of the civilised world would be there in the interests of veterinary science and for the sake of the profession it was important that they should do all they could to lend support to the cause.

Dr. O. C. BRADLEY, in proposing "The Medical Profession," said that the veterinary profession looked to the medical profession for a certain amount of guidance, and followed their lead in more respects than one. They desired that they in the veterinary profession should occupy the same status as the medical profession. He would, however, like to ask: Why could not the medical profession have been happy with the preliminary examination which they had? If this had not been altered the veterinary profession would not have been faced with such a problem themselves. Could not some mode be devised by which they could still lay claim to have as good an entrance examination as the other profession. He could conceive that if they were to depart from the standard which the medical profession had set up, the finger of scorn might be pointed to them. That was a point of course upon which there might be more than one opinion, but he did think that they might find a way out of the difficulty not by raising the standard of the preliminary examination in the orthodox sense, but in altering the nature of the test. He thought every boy ought not to be compelled to pass in a classical language, and the educational value of the preliminary examination might be increased without doing what was generally meant by the expression "raising the standard." It was clear that in the future the two professions would become more and more united, and they would have to work together much more than they had in the past. Problems of public health must be attacked by both professions and not simply by one. He would ask where would extension of civilisation be if the two professions did not work together? Civilisation could not spread without animals; and incidentally it could not extend without men. Obviously the two absolute essentials were men

and animals, or, if he might narrow it down, in other terms, the medical man and the veterinary surgeon.

Dr. DENNISON, in replying to the toast, referred to the operations of the National Insurance Act. Although he did not like it he had got to tolerate it better. From the monetary point of view he thought the medical profession would be paid; and had thought so before the Act came into operation. But, he asked, was money all the professional man wanted? He took it that as members of honourable professions, so long as they had sufficient in the way of necessities to make their lives happy and comfortable, money was by no means the first object in their life. They were not merchants, out to make a lot of money, but they were there in scientific interests, and their first care should be the helping forward of science to obtain further and more extended knowledge whereby to do good to one's fellow men and fellow creatures. Looking round the city they would see that motor cars were being used by medical men at the present day out of all proportion to what had been in use before. That was because of the increased rush because of the increased number of patients to be seen, and he feared the result was that there was not that careful scientific interest taken in each case that there used to be before the Act came into operation. The natural result was that the medical man got slacker in his work, there was neither the interest nor the justification to be found in taking that deep interest in cases, because there was less time available; and, moreover, in many cases it was often found to be some minor ailment that could have been rectified by obtaining a shilling bottle of medicine from the chemist. Again, with all the statistics that the Chancellor of the Exchequer might be able to produce with the large staff of statistical clerks that must be employed to collect the material and compile it, he did not think when it was all there it was going to be of great scientific interest compared with the individual efforts of the members of the profession. He feared that the Act would bring lower class men into the profession who would grasp at the money paid through the agency of the State, at the cost of individual scientific interest and research. With regard to the preliminary examination standard he thought one of the greatest mistakes the medical profession had ever made was in reducing that standard. How it might be varied was a matter for consideration, but to lower the first obstacle in the way he thought was a mistake. There was one matter he would like to mention, and that was the National Conference on Tuberculosis which would be held in July. Why should they not have a veterinary section in these Conferences? They were dependent upon the gentlemen of the veterinary profession to keep the milk supply pure in the country and to look after the meat provision, and he was glad they were being allowed to make experimental research in local areas in regard to swine fever. He understood that Denmark at the present day were sending swine into Great Britain at a very rapidly increasing rate to make up for the decreased number of swine in this country during the last twelve months. It seemed to him barbarous that directly swine fever was found to be in a place an order should be given for the whole lot to be killed. He could not understand why that principle should be kept to so long without any attempt being made at isolating suspicious cases. What had all the killing of swine done in this country in the way of preventing swine fever?

Mr. MASON presented the toast of "Kindred Societies," and remarked that he very much regretted none of their Lancashire friends were present, as it was the first time in the history of the Society he remembered that being the case.

Mr. GARNETT, in responding, touched upon the question of swine fever, and stated that he had been a

member for some years of the Departmental Committee dealing with the subject. He thought it was not possible for a person to deliver an opinion upon the serum treatment unless he had gone into the question and studied it thoroughly. The serum treatment alone gave protection against swine fever at the outside for a period of only 14 days. If serum treatment was taken in conjunction with an inoculation with active disease there was protection to the animal itself which might extend to its life, but it rendered that animal liable to be a "carrier" for the rest of its life to any other animals it might come in contact with. To propose that such a scheme as that should be applied broadcast in England with the removal of all restrictions was absolutely impossible. They were attacking the question of swine fever from a totally different point of view from the way it was being done on the Continent. In Denmark there was practically no swine fever. In Holland, where they had a great amount of it, they did not attempt to prevent it; it was not even a scheduled disease. In Hungary, which was the home of the serum treatment, they had applied the treatment, but with the most stringent regulations. In the United States, where the treatment had been extended to a far greater extent than any other country in the world, the great increase of the disease to-day was attributed to inoculation *plus* natural infection. He thought the remarks that were being made to-day in regard to the Board of Agriculture and their procedure with regard to swine fever were not doing justice to them—simply through a lack of knowledge of the facts.

Mr. CRAWFORD proposed the toast of "The Chairman," to which Mr. McKinna briefly responded.

During the evening the speeches were interspersed with items from an excellent musical programme given by Messrs. J. Holt, W. Hayle, G. R. Lister, and E. E. Johnson.

J. CLARKSON, Hon. Sec.

CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, March 5th, Prof. G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book: Messrs. W. R. Davis, F. J. Taylor, J. B. Buxton, R. Bennett, N. Almond, F. G. Samson, M. Cahill, J. Willett, R. Eaglesham, L. A. Auchterlonie, B. A. McGuire, G. Upton, W. S. Mulvey, Prof. E. B. Reynolds, H. D. Jones, E. L. Stroud, S. H. Slocock, W. L. Harrison, S. L. Slocock, J. W. McIntosh, W. D. Halfhead, T. S. Price, H. King, W. Perryman, A. E. Willett, F. W. Willett, and Hugh A. MacCormack, hon. sec.

Visitors: Prof. Lander, Messrs. J. T. Edwards, W. B. Howe, T. C. Toope, and R. Daubney.

On the motion of Mr. Bennett, seconded by Mr. Stroud, the minutes of the last meeting were taken as read and signed.

Correspondence. The Hon. Sec. stated he had received a communication from Mr. Geo. H. Livesey explaining his inability to attend and present item 6 on the agenda, entitled "A Case of Rupture of the Uterus in the Bitch."

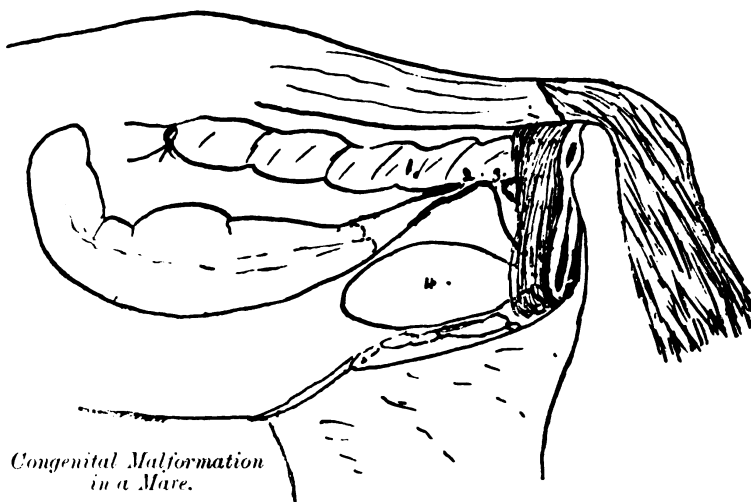

The Hon. Sec. further stated that he had received certain publications from Major Holmes and Dr. Hartley, of the Department of Agriculture, India, relating to rinderpest.

It was decided that the thanks of the Society be tendered to Major Holmes and Dr. Hartley for the above publications.

Nomination. Mr. JOHN BROWNLESS, M.R.C.V.S., St. Mary Abbott's Terrace, Kensington, was nominated, and will come up for election at the next meeting.

SPECIMENS.

Mr. J. B. BUXTON submitted a specimen of strongyle from the fourth stomach of a goat which had set up a fatal gastritis. The case had previously been recorded in *The Veterinary Journal*.

Congenital Malformation in a Mare.

1. Rectum. 2. Vagina opening into rectum. 3. Opening and connection between rectum and vulva. 4. Bladder.

Mr. A. E. WILLETT submitted two cases. The first was that of a mare. Faeces were noticed in the vulva of the mare, and it was thought that a rupture might have occurred. Examination per rectum showed an orifice, with apparently a downward direction, this orifice coming out in the vulva. Feeling further, the speaker had found another orifice, into which he had been able to insert his finger, until he met what he took to be the os uteri. On examination per vulvam he had found no other orifice than that of the urethra. The speaker exhibited a rough sketch.

Mr. PERRYMAN regarded Mr. Willett's diagram with interest. There appeared to be two sinus wounds or false openings, and he would like to know whether the faeces worked down from the front opening towards the uterus; also, if there were any tendency to septic infection of the parts. Was the mare in a condition to pass faeces, both by the rectum and the vagina?

Mr. WILLETT: The animal was in perfect health. He had examined her from the posterior opening. The anterior opening to the vagina seemed to act as a valve, and did not show any tendency to allow the faeces to pass down.

Prof. REYNOLDS desired to ask Mr. Willett how long faeces had been noticed in the vulva, and what was the age of the mare. Did Mr. Willett think, after he had made his examination, that the case was one of congenital deformity, or the result of injury or accident?

In reply to Prof. Reynolds, Mr. Willett said he had no doubt that the deformity was congenital. The driver first noticed faeces in the vulva. The mare was six years old.

The second case was malformed fetus of an Ayrshire cow. The cow had calved on the Friday morning. The cattlemen applied a West's clamp on Sunday morning, and while struggling with this application another foot protruded. The speaker went to see the animal and found another fetus, all four legs in the passage, the hind legs protruding. The next felt, after the hind legs, was an aborted foreleg, further back was a well formed foreleg. He resorted to embryotomy, removing all the legs, the head as a result coming quite easily into the vagina. When the fetus was removed from the cow it was found that the hind legs were growing through the chest—as if in a sitting position—coming out in front of the head. The thorax was turned completely inside out and backwards, so that the false ribs were nearer to the neck. All the abdominal and thoracic organs were external to the body. The embryotomy precluded the possibility of getting a photograph.

The PRESIDENT remarked that, in his experience, the malformation of the genital passages recorded by Mr. Willett was unique, and very interesting. The foetal monstrosity was not quite so rare; he had met with several such cases. Unfortunately it was seldom that the fetuses could be delivered whole so that a good photograph could be obtained.

The speaker (Prof. Wooldridge) then exhibited a series of navicular bones, including one of a horse, seen in consultation with Mr. T. S. Price, injured by picking up a nail, which he had submitted at the previous meeting. At that meeting he had mentioned that in cases where, as a result of a picked-up nail, there was inflammation of the bursa of the navicular with ulceration of the synovial lining of that bursa, the best thing that could occur would be the adhesion of the tendon to the navicular bone, and that, the speaker had indicated, would have been likely to result in permanent lameness. He also said that he saw no advantage in treating cases where it was certain that the navicular bone had been penetrated.

The speaker had since come into possession of the navicular bone of a horse seen with Mr. West and Mr. Stewart which had picked up a nail as far back as October last, and had been under treatment ever since. The animal was still acutely lame, and when slaughtered, Prof. Wooldridge had found that almost the whole of the posterior face was firmly adherent to the flexor pedal tendon, and round the rim of it there was the exostosis which could be plainly seen in the specimen submitted. To his surprise, however, there was no indication of bone disease involving either the coronet or the pedal bone. For a few yards the horse had been able to walk fairly well, but when he struck his toe he would hop along on three legs with the damaged foot suspended high in the air. The post mortem justified the step taken. Above the pedal bone and behind the coronet bone was a cavity containing inflammatory blood-stained exudate. There was a small track on each side which would about admit a coarse knitting needle. On one side the track opened up to the heel; on the other side it was blind, and did not reach the skin.

The third specimen submitted, for which he was indebted to Mr. West and Mr. Southall, represented a case of injury either by a nail or glass—such as broken bottle—although no actual body causing the mischief was found. A suppurating condition of the foot was discovered in August last. The puncture of the foot on the side of the frog was opened, and pus liberated, the horse making an apparently uninterrupted recovery and being set to work in the middle of September. It was improbable that this was connected in any way with the later trouble. At the beginning of January last, however, it again became lame, rather suddenly. The owner, thinking the horse was nail-bound, sent it to the forge

to have the shoe removed and replaced. Nothing was found wrong, and the horse went along better for two or three days, when it became acutely bad. The veterinary surgeon was called in, and found a punctured track between the frog and the bar; this was pared well down and pus liberated. The puncture had evidently been in existence for some days before attention had been called to it. The underrun horn was removed, and good drainage was promoted. In spite of that the horse kept acutely lame, and by the middle of February was not improving. On manipulating and pressing the back of the pastern a considerable quantity of pus spurted out—estimated at an ounce—but no relief followed. The destruction of the horse was then advised. The owner refused this for a fortnight, but a couple of days before slaughter there was a breaking out at the heel. The post-mortem showed that the navicular bone was ulcerated almost completely through, and had the horse attempted to work in that condition the navicular bone itself would have been smashed. The rim of the coronet bone was also affected, and there was erosion and slight exostosis of the pedal bone on the right (outer) wing. Further, there was ossification—with little grooves, probably due to pus—of both cartilages. It was interesting to compare the three navicular bones and work out, from the conditions existing, the advisability of recommending slaughter at an early date in such cases, rather than protract the case and slaughter the animal in the end. It required courage to advise the destruction of a horse worth £80, and it was small wonder that one procrastinated—hoping against hope.

Prof. WOOLDRIDGE also submitted a case of intussusception of the ileum through the ileo-caecal valve into the large intestine of a Pekingese puppy, aged six months. The condition was most frequently associated with worms, but no worms could be found in this puppy. The bowel, except for the affected portion, was healthy. The large bowel had been split open, and the intussusception, resembling a finger lying on the face of the bowel, was exposed. At one end the ileum would be seen and the caecum to one side.

Mr. W. R. DAVIS enquired whether in every case of a gathered nail wounding the frog and followed by escape of synovia the President would advise slaughter. [Prof. Wooldridge replied in the negative].

The PRESIDENT, with further reference to the intussusception case, said that the puppy had suddenly become frantic, and the owner had immediately destroyed him. There had therefore been no opportunity to diagnose or treat the case during life. Probably the trouble had been of very short duration.

Mr. J. W. McINTOSH exhibited two small pieces of bone and two small pieces of charcoal removed from a strangulated scrotal hernia in a little dog, six months old, belonging to himself. The case was unusual. The dog was getting over distemper, and on Tuesday night last the speaker noticed a swelling of the scrotum which, on manipulation, proved hard though not large. He had also asked Prof. Wooldridge to look at the animal, which the Professor did. The case was puzzling, because the animal had been passing faeces freely all day (Thursday) and was quite lively. Prof. Wooldridge operated on the dog, which, however, died within 24 hours, on the Saturday. The swelling was painless.

The PRESIDENT supplemented the remarks of Mr. McIntosh. He had been misled in his diagnosis when he first saw the dog; except for the swelling of the scrotum, there was no indication of strangulated hernia. The dog passed faeces normally and in considerable quantity, was feeding fairly well. All that could be found was that some body in the scrotum crepitated when manipulated. Being a cold and painless swelling, he had been misled as to the condition. Mr. McIntosh had said that he was not certain that there had not been a swelling for some time previously. The dog had not

been examined at all minutely, as there did not seem cause. But for extreme thinness, following distemper, the dog appeared quite happy. It seemed attempting murder to operate there and then. It was therefore suggested that the dog should be got into better condition, and then explored. Next day the animal had a fistula, and, upon operating under A.C.E. anaesthesia it was found that there was an adhesion between the bowel and the base of the scrotum. The adhesions were broken down and the foreign bodies were removed and the bowel sutured. Even then the bowel was decidedly thickened, and could not be returned to the body cavity until the inguinal ring had been materially enlarged. At 2 o'clock the next day the dog collapsed after appearing very bright during the morning, and died in half-an-hour; it was a case of collapse as there had not been time for peritonitis to be established.

Mr. G. UPTON desired to refer to Mr. Willett's remarks, as he had known several cases, particularly with mares that had foaled too young. The slightest rent between the vagina and rectum would set up the trouble. A rent should never be made when a cow was in parturition; hæmorrhage led to a serious state of affairs. He remembered a case of a mare which had torn herself slightly, with the result that a fistula was formed which would not heal; faeces passed through.

POISONING BY CASTOR SEEDS (*RICINUS*).

Prof. G. D. LANDER, D.Sc., Royal Vety. College.

The castor oil plant belongs to the *Euphorbiaceae*, and comprises many varieties of *Ricinus communis*, some of which are cultivated as ornamental hothouse plants. *R. communis* contains the toxine ricine which, according to Stillmark, is also contained in ten other varieties. Probably *Jatropha curcas*, purging nut, or Barbados seed also contains ricine, whilst *Croton tiglium*, belonging to the same order, contains the toxine crotonine. *Abrus precatorius*, the crab's eye or jequirity, containing abrine, is a leguminous plant.

There is a great variation in the size and appearance of varieties of castor seed. At the present moment the seeds purchasable in the London market are of a small variety of the common and well-known drab and mottled seed. I have lately used seeds of this kind obtained through four district agencies. They average 135 seeds to the ounce, whilst specimens of *Ricinus sanguineus* and *Ricinus Zanzibariensis*, with which we have also experimented, averaged 66 and 39 seeds respectively to the ounce.

The relative proportion of husk to seed is important, and is for the specimens we used as follows:

R. communis. *R. sanguineus* *R. Zanzibariensis.*

Husk	30 per cent.	25 per cent.	21 per cent.
Seed	70 "	75 "	79 "

In spite of the well-known dangerous character of the castor oil seeds they are not uncommonly encountered in horse mixtures and in cakes. A cotton cake shown to me recently by Sir John M'Fadyean had with it about 7 per cent. of whole castor seeds, and in the broken material we were also able to find at least 1 per cent. of fragments of husk and endosperm.

Although recorded cases in the veterinary literature are very few, cases of castor seed poisoning may, and do, occur from time to time. Their incidence is not necessarily confined to the cattle practice of the country, but the horse in towns may also be the victim through adulteration of foods. The pressed cake left after the expression of castor oil is, by reason of its ricine content, quite unsuitable as a food, although the usual chemical analysis, which merely displays the percentages of fat, proteins, carbohydrates, etc., would tend to indicate an excellent standard of dietetic value.

Properties of Ricine. The toxine ricine occurs in the endosperm and embryo, but not in the husk of the seed. The decorticated and air-dried seeds give 2.8 per cent. of a ricine preparation by extraction with 10 per cent. salt solution, precipitation by magnesium sulphate, and removal of the salts by dialysis. This preparation is not pure ricine, and no doubt contains a large proportion of albumins.

The active principle is not digested by trypsin. After tryptic digestion the quantity of precipitable albumen becomes almost negligible, although the toxicity is quantitatively preserved. The chemical nature of ricine thus appears to be analagous to that usually ascribed at the present time to the bacterial toxins and ferments, and the name toxalbumen is abandoned. Ricine differs in a marked manner from the bacterial toxins and snake venoms by its relative stability towards the natural fluids and ferments of the alimentary tract. For this reason it is absorbed from the intact alimentary tract, and thus may act as a poison when administered by the mouth. Nevertheless, the toxicity by this channel is at least a hundredfold less than the toxicity when administered by subcutaneous injection.

The toxicity by injection is enormous. According to Ehrlich 1-2000th of a grain per 2lb. body weight; 1 gram (15.43 grains) subcutaneously kills 1½ million guinea-pigs; 3 grains by the mouth is stated to be poisonous to the grown man, and it must be remembered that these figures do not refer to pure ricine but to ricine contaminated with more or less of albumen. Ricine is comparatively thermo-stable, it withstands a dry heat of 110° C., is not destroyed at a moist heat of 50° C., but is so at a moist heat of 100° C.

Symptoms of Poisoning. After injection the first symptom is a rise in temperature and a rapid fall in body weight. The decrease in weight is greater, and about twice as much as that caused by starvation. There are bloody motions, and albumen, and sometimes also blood in the urine. After 24 to 30 hours fatal symptoms suddenly declare themselves, beginning with clonic convulsions, spasmodic movements, weakening of the reflexes, and paralysis; after 15 minutes the convulsions are repeated, and half-an-hour after the onset of fatal symptoms there are dyspnoea and laboured inspirations, and death supervenes. Sometimes the spasms are absent. At the end there are severe central disturbances of the *medulla oblongata*, vaso-motor and respiratory paralysis. The blood pressure sinks. On post-mortem examination there is observed swelling and reddening of the subcutaneous lymph sacs. Great enlargement and reddening of the mesenteric lymph sacs and Peyer's patches, numerous ecchymoses in the intestine, but no ulceration, the spleen greatly enlarged and soft; thromboses are not found. The intestinal ecchymosis is considered to be due to the entrance of ricine from the circulation into the alimentary canal.

These observations, however, have very little value outside the laboratory being observed after injection, for the case likely to arise in practice is that of poisoning by way of the alimentary canal.

The Horse. The horse is very susceptible to poisoning by castor seeds. According to Miessner 450 to 750 grains weight of the seeds, or on the average 600, will fatally poison a horse. Allowing a ricine content of 2.8 per cent. this is equivalent to a dose by the mouth of only 16.8 grains, and again it must be remarked that by far the larger portion of this 2.8 per cent. is not ricine. The actual number of seeds naturally varies with their size.

In the English literature I have only succeeded in finding one case, viz., that published by Broad in *The Veterinary Record* of 1896, p. 226. Broad observed complete loss of appetite, shivering, coldness of the extremities, dejection, abdominal pain, and constipation.

Temperature 103° F. pulse 70. death took place in about three days. One is rather struck by the constipation, as the seeds were presumably not defatted.

In June of last year, Mr. R. Shenton, of Tideswell, sent me a sample of Indian corn, the use of which was supposed to have produced symptoms of poisoning in eight horses. These symptoms were, in Mr. Shenton's own words, "extreme dullness, with well-marked prostration, the eye looking especially dull. Pulse 60-80, temperature ranging from 102° to 104°. Constipation was present in all cases except one, in which there was diarrhoea, and this case rapidly recovered. There was total loss of appetite, and spasm of the diaphragm was a well-marked symptom. In only one case was there marked abdominal pain evinced by the ordinary signs. These symptoms gradually passed off after the administration of laxatives in two to five days."

On investigating the food I found a considerable proportion of broken castor seeds in it, and it was particularly pleasing to observe the excellent general agreement between the symptoms noted in Broad's and Shenton's cases.

CROTON POISONING OF HORSES.

The present occasion seems a good one for putting on record an interesting case of the poisoning of horses by croton. The cases were observed by Messrs. R. E. Godbold, of Sudbury, and Morton Wallis, of Halstead, and I am indebted to my colleague, Prof. Reynolds, for the details.

Croton seeds had been passed through a mill, which was then used for grinding rations for pigs and horses. About 300 pigs had the food, all vomited, and were severely purged, but none died.

Nine horses had the food, as it came from the mill, so that the quantity of croton taken decreased from the first horse onwards.

Symptoms. The pulse was hard, wiry, and quick; breathing accelerated; sweating, pawing, and crouching; constant and very violent purgation; temperature ranged from 103°—105° F. Three grains morphine sulphate in saline, or an equivalent quantity of tincture of opium in drenches of mucilage, corn flour, or arrowroot every few four hours was advised.

Recovery took place in about a fortnight in all cases save one. Unfortunately the carcase in the fatal case was removed before a post-mortem could be made.

The drastic irritant effects of croton oil constitute an important difference between these cases and those of ricine poisoning.

The Ox. Miessner gives the toxic dose of castor seeds for the ox as from 11 to 12½ ounces, that is about 10 times as large a dose as for the horse. This is an interesting illustration in the variation of susceptibility of different genera. The difference is very great and reminds one of the opposite difference in susceptibility to lead, towards which the horse is believed to be ten times as tolerant as the ox.

Mr. J. T. Edwards, M.R.C.V.S., B.Sc., and myself have been experimenting lately on the effects of castor seeds on the ox, and some of our results are interesting. So far as concerns fatal poisoning, our earlier experiments with the ordinary small seeds to which I referred above were not productive of positive results. I shall, therefore, briefly summarise them without giving the full clinical records in detail.
